Headings formatted in ***bold-italic*** have changed since the last version.

- Preface
  - Welcome to the Book! xliii
  - The Book's Structure xliii
  - ***The Trails ..... xliv***
  - About the Updates l
  - ***What's New in Version 8.10? ..... l***
  - Warescription l
  - About the APK Edition li
  - Book Bug Bounty lii
  - Source Code and Its License liii
  - ***Creative Commons and the Four-to-Free (42F) Guarantee ..... liv***
  - Acknowledgments liv
- Key Android Concepts
  - Android Applications 1
  - ***Android Devices 6***
  - Don't Be Scared 10
- Choosing Your Development Toolchain
  - Android Studio 11
  - Eclipse 11
  - IntelliJ IDEA 12
  - Command-Line Builds via Gradle 12
  - Yet Other Alternatives 12
  - IDEs... And This Book 13
  - What We Are Not Covering 13
- Tutorial #1 - Installing the Tools
  - But First, Some Notes About Android's Emulator 15
  - Step #1: Checking Your Hardware 16
  - ***Step #2: Setting Up Java and 32-Bit Linux Support 17***
  - ***Step #3: Install Android Studio 17***
  - Step #4: Install the SDKs and Add-Ons 19
  - In Our Next Episode... 27
- Android and Projects
  - ***Projects and Android Studio 29***
  - Starter Project Generators 35
- Tutorial #2 - Creating a Stub Project

- About Our Tutorial Project 37
- About the Rest of the Tutorials 38
- About Our Tools 38
- Step #1: Importing the Project 38
- Step #2: Get Ready for the x86 Emulator 42
- Step #3: Set Up the AVD 43
- Step #4: Set Up the Device 50
- ***Step #5: Running the Project 55***
- In Our Next Episode... 57

• Getting Around Android Studio
- Navigating The Project Explorer 59
- Running Projects 62
- Viewing Output 63
- Accessing Android Tools 64
- Android Studio and Release Channels 66
- Visit the Trails! 67

• Contents of Android Projects
- What You Get, In General 69
- More About the Directory Structure 72
- What You Get Out Of It 74

• Introducing Gradle and the Manifest
- Gradle: The Big Questions 75
- Obtaining Gradle 77
- Versions of Gradle and the Android Gradle Plugin 79
- Gradle Environment Variables 80
- Examining the Gradle Files 80
- Introducing the Manifest 83
- Things In Common Between the Manifest and Gradle 84
- Other Gradle Items of Note 86
- Where's the GUI? 87
- The Rest of the Manifest 87
- Learning More About Gradle 90
- Visit the Trails! 90

• Tutorial #3 - Manifest Changes
- Some Notes About Relative Paths 91
- Step #1: Supporting Screens 91
- Step #2: Blocking Backups 92
- Step #3: Ignoring Lint 92
- In Our Next Episode... 94

• Some Words About Resources
- String Theory 95

- Got the Picture? 101
- Dimensions 105
- The Resource That Shall Not Be Named... Yet 107

- Icons
  - App Icons... And Everything Else 109
  - Creating an App Icon with the Asset Studio 110
  - Creating Other Icons with the Asset Studio 115
- Tutorial #4 - Adjusting Our Resources
  - Step #1: Changing the Name 117
  - Step #2: Changing the Icon 118
  - Step #3: Running the Result 122
  - In Our Next Episode... 123
- The Theory of Widgets
  - What Are Widgets? 125
  - Size, Margins, and Padding 127
  - What Are Containers? 127
  - The Absolute Positioning Anti-Pattern 128
  - The Theme of This Section: Themes 129
- The Android User Interface
  - The Activity 133
  - Dissecting the Activity 134
  - Using XML-Based Layouts 135
- Basic Widgets
  - Common Concepts 139
  - Introducing the Graphical Layout Editor 142
  - And Now, Some Notes About the Book's Sample Projects 151
  - Assigning Labels 152
  - A Commanding Button 157
  - Fleeting Images 160
  - Fields of Green. Or Other Colors. 166
  - More Common Concepts 169
  - Visit the Trails! 172
- Debugging Your App
  - Get Thee To a Stack Trace 174
  - The Case of the Confounding Class Cast 175
  - Point Break 176
- The Classic Container Classes
  - Introducing the Sampler App 177
  - RTL and Your Layouts 178
  - LinearLayout and the Box Model 179
  - All Things Are Relative 203

- Tabula Rasa 214
- Hey, What About ConstraintLayout? 220
- Turning Back to RTL 221

• Other Common Widgets and Containers
- Just a Box to Check 223
- Don't Like Checkboxes? How About Toggles or Switches? 226
- Turn the Radio Up 230
- Scrollwork 233
- Making Progress with ProgressBars 236
- Framing the Scene 237
- Visit the Trails! 238

• Tutorial #5 - Creating a Layout
- Step #1: Creating a New Layout Resource 239
- Step #2: Defining the UI 240
- In Our Next Episode... 245

• GUI Building, Continued
- Making Your Selection 247
- Including Includes 248
- Preview of Coming Attractions 250

• AdapterViews and Adapters
- Adapting to the Circumstances 251
- Lists of Naughty and Nice 253
- Clicks versus Selections 255
- Spin Control 259
- Grid Your Lions (Or Something Like That...) 262
- Fields: Now With 35% Less Typing! 266
- Customizing the Adapter 270
- Visit the Trails! 279

• The WebView Widget
- Role of WebView 281
- Daddy, Where Do WebViews Come From? 282
- Adding the Widget 282
- Loading Content Via a URL 283
- Links and Redirects 285
- Supporting JavaScript 285
- Alternatives for Loading Content 286
- Listening for Events 287
- Addressing the Link/Redirect Behavior 290
- Visit the Trails! 292

• Defining and Using Styles
- Styles: DIY DRY 293

    - Elements of Style 295
    - Themes: Would a Style By Any Other Name... 298
    - What Happens If You Have No Theme 299
    - Android Studio's Theme Editor 299
- Dependencies
    - What's a Dependency? 305
    - Dependency Scopes 306
    - Depending on a Local JAR 307
    - What's an Artifact? 308
    - Artifacts and Repositories 308
    - Major Library Families from Google 308
    - Requesting Dependencies 309
    - The Android Support Library 312
- Tutorial #6 - Adding a Library
    - Step #1: Getting Rid of Existing Cruft 317
    - Step #2: Requesting New Dependencies 318
    - In Our Next Episode... 320
- Introducing ConstraintLayout
    - Why Another Container? 321
    - Comparing with the Classics 323
    - Getting ConstraintLayout 323
    - Using Widgets and Containers from Libraries 325
    - Using a ConstraintLayout 325
    - Converting Existing Layouts 341
    - Visit the Trails! 343
- The Action Bar
    - Bar Hopping 345
    - Yet Another History Lesson 351
    - Your Action Bar Options 352
    - Setting the Target 354
    - Defining the Resource 355
    - Applying the Resource 358
    - Responding to Events 358
    - The Rest of the Sample Activity 359
    - MENU Key, We Hardly Knew Ye 365
    - Action Bars, Live in Living Color! 366
    - Visit the Trails! 376
- Vector Drawables
    - Getting the Artwork 377
    - VectorDrawableCompat 382
    - Other VectorDrawable Backports 390

- Tutorial #7 - Setting Up the Action Bar
  - Step #1: Adding Some Icons 391
  - Step #2: Defining Some Options 393
  - Step #3: Loading and Responding to Our Options 396
  - Step #4: Supporting Older Devices 397
  - Step #5: Trying It Out 398
  - In Our Next Episode... 400
- Android's Process Model
  - When Processes Are Created 401
  - BACK, HOME, and Your Process 402
  - Termination 403
  - Foreground Means "I Love You" 404
  - You and Your Heap 404
- Activities and Their Lifecycles
  - Creating Your Second (and Third and...) Activity 406
  - Warning! Contains Explicit Intents! 410
  - Using Implicit Intents 412
  - Extra! Extra! 418
  - Pondering Parcelable 419
  - Asynchronicity and Results 421
  - Schroedinger's Activity 421
  - Life, Death, and Your Activity 422
  - When Activities Die 424
  - Walking Through the Lifecycle 425
  - Recycling Activities 428
  - Application: Transcending the Activity 429
  - The Case of the Invisible Activity 430
- Tutorial #8 - Setting Up An Activity
  - Step #1: Creating the Stub Activity Class and Manifest Entry 433
  - Step #2: Launching Our Activity 435
  - In Our Next Episode... 436
- The Tactics of Fragments
  - The Six Questions 437
  - Where You Get Your Fragments From 440
  - Your First Fragment 440
  - The Fragment Lifecycle Methods 444
  - Your First Dynamic Fragment 445
  - Fragments and the Action Bar 448
  - Fragments Within Fragments: Just Say "Maybe" 450
  - Fragments and Multiple Activities 450
- Tutorial #9 - Starting Our Fragments

    - Step #1: Create a SimpleContentFragment 453
    - Step #2: Examining SimpleContentFragment 455
    - In Our Next Episode... 456
- Swiping with ViewPager
    - Pieces of a Pager 457
    - ***Paging Fragments 458***
    - Paging Other Stuff 463
    - Indicators 464
    - Revisiting the Containers Sampler 467
- Tutorial #10 - Rigging Up a ViewPager
    - Step #1: Add a ViewPager to the Layout 475
    - Step #2: Creating a ContentsAdapter 476
    - Step #3: Setting Up the ViewPager 477
    - In Our Next Episode... 480
- Resource Sets and Configurations
    - What's a Configuration? And How Do They Change? 481
    - Configurations and Resource Sets 482
    - Screen Size and Orientation 483
    - Coping with Complexity 486
    - Choosing The Right Resource 487
    - API-Versioned Resources 491
    - ***Default Change Behavior 493***
    - State Saving Scenarios 495
    - Your Options for Configuration Changes 496
    - Blocking Rotations 510
    - And Now, a Word From the Android Project View 511
    - Configuration Challenges 512
- Material Design Basics
    - Your App, in Technicolor! 517
- Dealing with Threads
    - The Main Application Thread 523
    - Getting to the Background 525
    - ***Asyncing Feeling 525***
    - Alternatives to AsyncTask 534
    - And Now, The Caveats 536
    - Event Buses 537
    - Visit the Trails! 545
- Requesting Permissions
    - Frequently-Asked Questions About Permissions 548
    - Characteristics of Permissions 553
    - New Permissions in Old Applications 556

- Android 6.0+ Runtime Permission System 557
- A Simple Runtime Permission Abstraction 569

- Assets, Files, and Data Parsing
  - Packaging Files with Your App 573
  - Files and Android 575
  - Working with Internal Storage 576
  - Working with External Storage 585
  - Removable Storage 592
  - Multiple User Accounts 593
  - Linux Filesystems: You Sync, You Win 593
  - StrictMode: Avoiding Janky Code 595
  - Files, and Your Development Machine 597
  - XML Parsing Options 605
  - JSON Parsing Options 606
  - Using Files with Implicit Intents 606
  - Visit the Trails! 607
- Tutorial #11 - Adding Simple Content
  - Step #1: Adding Some Content 609
  - Step #2: Using SimpleContentFragment 610
  - Step #3: Launching Our Activities, For Real This Time 611
  - Step #4: Getting a Bit More Material 612
  - Step #5: Seeing the Results 614
  - In Our Next Episode... 616
- Tutorial #12 - Displaying the Book
  - Step #1: Adding a Book 617
  - Step #2: Creating a ModelFragment 618
  - Step #3: Defining Our Model 619
  - Step #4: Examining Our Model 621
  - Step #5: Defining Our Event 621
  - Step #6: Loading Our Model 622
  - Step #7: Registering for Events 625
  - Step #8: Adapting the Content 626
  - Step #9: Showing the Content When Loaded 627
  - Step #10: Attaching our ModelFragment 628
  - Step #11: Showing the Content After a Configuration Change 629
  - Step #12: Setting Up StrictMode 630
  - In Our Next Episode... 631
- Using Preferences
  - Getting What You Want 633
  - Stating Your Preference 634
  - Collecting Preferences with PreferenceFragment 635

- Android Studio's Preferences Editor 642
- Types of Preferences 643

- Tutorial #13 - Using Some Preferences
  - Step #1: Defining the Preference XML Files 649
  - Step #2: Creating Our Preference Activity 653
  - Step #3: Adding To Our Action Bar 654
  - Step #4: Launching the Preference Activity 654
  - Step #5: Loading the Preferences 657
  - Step #6: Saving the Last-Read Position 661
  - Step #7: Restoring the Last-Read Position 662
  - Step #8: Keeping the Screen On 663
  - In Our Next Episode... 665
- SQLite Databases
  - Introducing SQLite 667
  - Thinking About Schemas 668
  - Start with a Helper 668
  - Getting Data Out 673
  - The Rest of the CRUD 680
  - Hey, What About Hibernate? 686
  - But, What About Room? 686
  - Visit the Trails! 686
- Tutorial #14 - Saving Notes
  - Step #1: Adding a DatabaseHelper 689
  - Step #2: Examining DatabaseHelper 690
  - Step #3: Creating a NoteFragment 691
  - Step #4: Examining NoteFragment 692
  - Step #5: Creating the NoteActivity 692
  - Step #6: Examining NoteActivity 693
  - Step #7: Add Notes to the Action Bar 694
  - Step #8: Defining a NoteLoadedEvent 696
  - Step #9: Loading a Note from the Database 697
  - Step #10: Loading the Note Into the Fragment 698
  - Step #11: Updating the Database 699
  - Step #12: Saving the Note 700
  - Step #13: Adding a Delete Action Bar Item 702
  - Step #14: Closing the NoteFragment When Deleted 705
  - In Our Next Episode... 710
- Internet Access
  - DIY HTTP 711
  - What About HttpClient? 721
  - HTTP via DownloadManager 724

- Using Third-Party JARs 724
- SSL 725
- Using HTTP Client Libraries 725
- Visit the Trails 751

- Intents, Intent Filters
  - What's Your Intent? 753
  - Stating Your Intent(ions) 755
  - Responding to Implicit Intents 755
  - Requesting Implicit Intents 758
  - ShareActionProvider 762
  - Practice Safe Content Resolution 765
- Broadcasts and Broadcast Receivers
  - The Stopped State 769
  - Example System Broadcasts 770
  - The Order of Things 779
  - Keeping It Local 780
  - Visit the Trails! 780
- Tutorial #15 - Sharing Your Notes
  - Step #1: Adding a ShareActionProvider 781
  - Step #2: Sharing the Note 782
  - Step #3: Testing the Result 784
  - In Our Next Episode... 787
- Services and the Command Pattern
  - Why Services? 789
  - ***Setting Up a Service 790***
  - ***Communicating To Services 793***
  - ***Scenario: The Music Player 795***
  - Communicating From Services 798
  - ***Scenario: The Downloader 801***
  - ***JobIntentService 808***
  - ***IntentService or JobIntentService? 812***
  - Services and Configuration Changes 812
  - ***When Do Services End? 813***
  - ***Background Service Limitations 814***
- Tutorial #16 - Updating the Book
  - Step #1: Adding a Stub DownloadCheckService 819
  - Step #2: Tying the Service Into the Action Bar 820
  - Step #3: Defining Our Event 822
  - Step #4: Defining Our JSON 822
  - Step #5: Defining Our Retrofit Interface 823
  - Step #6: Retrieving Our JSON Via Retrofit 824

    - Step #7: Downloading the Update 826
    - Step #8: Unpacking the Update 827
    - Step #9: Using the Update 831
    - In Our Next Episode... 836
- Large-Screen Strategies and Tactics
    - Objective: Maximum Gain, Minimum Pain 837
    - The Fragment Strategy 837
    - Fragment Example: The List-and-Detail Pattern 846
    - Other Master-Detail Strategies 860
    - Showing More Pages 873
    - Fragment FAQs 879
    - Screen Size and Density Tactics 880
    - Other Considerations 883
- Tutorial #17 - Supporting Large Screens
    - Step #1: Creating Our Layouts 887
    - Step #2: Loading Our Sidebar Widgets 891
    - Step #3: Opening the Sidebar 892
    - Step #4: Loading Content Into the Sidebar 893
    - Step #5: Removing Content From the Sidebar 896
- Backwards Compatibility Strategies and Tactics
    - Think Forwards, Not Backwards 903
    - Aim Where You Are Going 905
    - A Target-Rich Environment 905
    - Lint: It's Not Just For Belly Buttons 906
    - A Little Help From Your Friends 907
    - Avoid the New on the Old 907
    - Testing 911
    - Keeping Track of Changes 911
- System Services
    - What is a System Service? 913
    - What System Services Are There? 914
- Google Play Services
    - What Is Google Play Services? 917
    - What Is In the Play Services SDK? 918
    - Adding Play Services to Your Project 925
- Getting Help
    - Questions. Sometimes, With Answers. 935
    - Heading to the Source 936
- Working with Library Modules
    - Prerequisites 939
    - Creating a Library Module 939

    - Using a Library Module 942
    - Library Modules and the Manifest 942
    - Library Modules and Transitive Dependencies 943
    - Limitations of Library Modules 944
- Gradle and Tasks
    - Key Build-Related Tasks 945
    - Results 948
- Gradle Build Variants
    - Prerequisites 949
    - Objectives of the Project Structure 949
    - Terminology 950
    - Configuring the Stock Build Types 953
    - Adding Build Types 957
    - Adding Product Flavors and Getting Build Variants 957
    - Doing the Splits 959
    - Gradle and Android Studio 961
- Manifest Merger Rules
    - Prerequisites 963
    - Manifest Scenarios 963
    - Pieces of Manifest Generation 965
    - Examining the Merger Results 967
    - Viewing Merged Manifests in Android Studio 967
    - Merging Elements and Attributes 968
    - Employing Placeholders 978
- Signing Your App
    - Prerequisites 983
    - Role of Code Signing 983
    - What Happens In Debug Mode 984
    - Production Signing Keys 985
- Distribution
    - Prerequisites 993
    - Get Ready To Go To Market 993
- Writing a Gradle Plugin
    - Prerequisites 999
    - Customizing a Gradle Build 999
    - Some Use Cases for a Custom Plugin 1000
    - Writing a Plugin 1001
    - Distributing the Plugin 1008
    - Using the Plugin 1010
    - Creating a Real Plugin 1014
- Code Generation

    - Prerequisites 1019
    - What Drives the Custom Code? 1019
    - Java as Poetry 1021
    - Writing a Code Generation Plugin 1022
    - Using the Generated Code 1033
- Advanced Gradle for Android Tips
    - Prerequisites 1035
    - Gradle, DRY 1035
    - Automating APK Version Information 1038
    - ***Adding to BuildConfig 1040***
- Testing with JUnit4
    - Prerequisites 1045
    - Instrumentation Tests and Unit Tests 1045
    - Writing JUnit4 Test Cases 1047
    - Configuring Gradle 1053
    - Running Your Instrumentation Tests 1054
    - Testing Android Library Projects 1059
    - Testing and Runtime Permissions 1059
    - The Android Test Orchestrator 1060
- Testing with Espresso
    - Prerequisites 1065
    - Adding a Shot of Espresso 1066
    - Writing Tests in Espresso 1068
    - The Espresso Test Recorder 1074
    - Stronger Espresso 1079
    - Opting Out of Analytics 1093
    - Waiting for the World to Change 1094
- Testing with UI Automator
    - Prerequisites 1099
    - What Is UI Automator? 1099
    - Why Choose UI Automator Over Alternatives? 1100
    - Gradle and Android Studio Settings 1100
    - Creating a Test Case 1101
    - Running Your Tests 1109
    - Finding Your Widgets 1109
    - Using the UI Automator Viewer 1110
- Measuring Test Coverage
    - Prerequisites 1113
    - Who Tests the Testers? 1113
    - Some Types of Test Coverage 1114
    - Coverage and Your Instrumentation Tests 1116

- Unit Testing
  - Prerequisites 1121
  - I Thought We Were Already Unit Testing? 1122
  - Scenario: Clean Architecture 1122
  - Setting Up Unit Testing 1123
  - Writing POJO Unit Tests 1126
  - Running Unit Tests 1130
  - ***Mocking Android 1135***
- MonkeyRunner and the Test Monkey
  - Prerequisites 1151
  - MonkeyRunner 1151
  - Monkeying Around 1153
- Java 8 Lambda Expressions
  - Prerequisites 1159
  - The Basic Idea 1160
  - Using Lambda Expressions 1161
  - Alternative: Method References 1165
- Rx Basics
  - Prerequisites 1167
  - Life is But a Stream 1167
  - Action and Reaction 1169
  - A Rx For What Ails You 1170
  - Rx and Lambdas 1171
  - ***A Simple Stream 1171***
  - Be Your Own Stream 1173
  - ***Removing the AsyncTask 1175***
  - Lambdas and Lifetimes 1181
  - Streaming from a Resource 1182
  - Error Handling 1183
  - Transmogrification 1184
  - ***Rx-Enabled Libraries 1185***
  - Further Reading 1187
  - What About LiveData? 1188
- Notifications
  - Prerequisites 1191
  - What's a Notification? 1191
  - Notifications and Channels 1194
  - Showing a Simple Notification 1194
  - The Activity-Or-Notification Scenario 1200
  - Big (and Rich) Notifications 1201
  - Foreground Services 1208

- Disabled Notifications 1211
- Advanced Notifications
  - Prerequisites 1215
  - Being a Good Citizen 1215
  - More About Channels 1216
  - Wear? There! 1223
  - Stacking Notifications 1228
  - Avoiding Wear 1234
  - Other Wear-Specific Notification Options 1235
  - Remote Input, On-Device 1249
  - Notification Groups 1254
  - Lockscreen Notifications 1256
  - Priority, Importance, and Heads-Up Notifications 1265
  - Full-Screen Notifications 1268
  - Progress Notifications 1270
  - Custom Views 1279
  - Life After Delete 1282
  - The Mysterious Case of the Missing Number 1283
  - Notifications and MessagingStyle 1283
  - Changes in API Level 23 1288
  - Sounds and Android 7.0 1289
  - Auto-Timeout 1290
  - Colorized Notifications 1291
- Multi-Window Support
  - Prerequisites 1295
  - A History of Windows 1295
  - What The User Sees 1296
  - What Your Code Sees 1298
  - Opting Out 1300
  - Opting In 1300
  - Configuring the Layout 1301
  - Avoiding Stutter 1303
  - Managing the Background 1304
  - How Low Can You Go? 1304
  - Parallel Processing 1305
  - Split-Screen, HOME, and Your Activity 1307
  - Split-Screen and Orientations 1308
  - Forcing Your App Into Multi-Window/Multi-Instance 1308
  - Supporting Legacy Proprietary Multi-Window 1316
  - Freeform Multi-Window Mode 1319
  - Picture-in-Picture 1326

- Multi-Display Support 1330
- Advanced ConstraintLayout
  - Prerequisites 1339
  - Disclosing Your Bias 1339
  - Centering Yourself 1345

Preface

Welcome to the Book!

Thanks!

Thanks for your interest in developing applications for Android! Android has grown from nothing to arguably the world's most popular smartphone OS in a few short years. Whether you are developing applications for the public, for your business or organization, or are just experimenting on your own, I think you will find Android to be an exciting and challenging area for exploration.

And, most of all, thanks for your interest in this book! I sincerely hope you find it useful and at least occasionally entertaining.

The Book's Structure

As you may have noticed, this is a rather large book.

To make this vast quantity of material manageable, the chapters are divided into the *core* chapters and a series of *trails*.

The core chapters represent many key concepts that Android developers need to understand in order to build an app. While an occasional "nice to have" topic will drift into the core — to help illustrate a point, for example — the core chapters generally are fairly essential.

The core chapters are designed to be read in sequence and will interleave both traditional technical book prose with tutorial chapters, to give you hands-on experience with the concepts being discussed. Most of the tutorials can be skipped,

though the first two — covering setting up your SDK environment and creating a project – everybody should read.

The bulk of the chapters are divided into trails, covering some particular general topic, from data storage to advanced UI effects to performance measurement and tuning. Each trail will have several chapters. However, those chapters, and the trails themselves, are not necessarily designed to be read in any order. Each chapter in the trails will point out prerequisite chapters or concepts that you will want to have covered in advance. Hence, these chapters are mostly reference material, for when you specifically want to learn something about a specific topic.

The core chapters will link to chapters in the trails, to show you where you can find material related to the chapter you just read. So between the book's table of contents, this preface, the search tool in your digital book reader, and the cross-chapter links, you should have plenty of ways of finding the material you want to read.

You are welcome to read the entire book front-to-back if you wish. The trails will appear after the core chapters. Those trails will be in a reasonably logical order, though you may have to hop around a bit to cover all of the prerequisites.

The Trails

Here is a list of all of the trails and the chapters that pertain to those trails, in order of appearance (except for those appearing in the list multiple times, where they span major categories):

Code Organization and Gradle

- Working with Library Projects
- Gradle and Tasks
- Gradle Build Variants
- Manifest Merger Rules
- Signing Your App
- Distribution
- Advanced Gradle for Android Tips

Testing

- Testing with JUnit4

- Testing with Espresso
- Testing with UIAutomator
- Measuring Test Coverage
- Unit Testing
- MonkeyRunner and the Test Monkey

Rx

- Java 8 Lambda Expressions
- Rx Basics

Advanced UI

- Notifications
- Advanced Notifications
- Multi-Window Support
- Advanced ConstraintLayout
- GridLayout
- Dialogs and DialogFragments
- Advanced ListViews
- Action Modes and Context Menus
- Other Advanced Action Bar Techniques
- Toolbar
- AppCompat: The Official Action Bar Backport
- RecyclerView
- Implementing a Navigation Drawer
- The Android Design Support Library
- Advanced Uses of WebView
- The Input Method Framework
- Fonts
- Rich Text
- Animators
- Legacy Animations
- Custom Drawables
- Mapping with Maps V2
- Crafting Your Own Views
- Advanced Preferences
- Custom Dialogs and Preferences
- Progress Indicators
- More Fun with Pagers

- Focus Management and Accessibility
- Miscellaneous UI Tricks
- Event Bus Alternatives
- Tasks
- The Assist API ("Now On Tap")
- The Auto-Fill API
- Data Binding
- Drag-and-Drop
- Keyboard and Mouse Input
- Viewing PDFs

Home Screen Effects

- Home Screen App Widgets
- Adapter-Based App Widgets

Security

- SSL
- NetCipher
- Encrypted Storage
- Advanced Permissions
- Restricted Profiles and UserManager
- Device Authentication
- Keys and the Keystore
- Miscellaneous Security Techniques

Data Storage and Retrieval

- Content Provider Theory
- Content Provider Implementation Patterns
- The Loader Framework
- The ContactsContract Provider
- The CalendarContract Provider
- The MediaStore Provider
- Consuming Documents
- Providing Documents
- Encrypted Storage
- Packaging and Distributing Data
- Advanced Database Techniques

- Data Backup

Advanced Network Topics

- SSL
- NetCipher
- Embedding a Web Server
- Miscellaneous Network Capabilities

Media

- Audio Playback
- Audio Recording
- Video Playback
- Using the Camera via 3rd-Party Apps
- Working Directly with the Camera
- The MediaStore Provider
- Media Routes
- Supporting External Displays
- Google Cast and ChromeCast
- The "10 Foot UI"
- Putting the TVs All Together: Decktastic
- Creating a MediaRouteProvider
- The Media Projection APIs

Hardware and System Services

- AlarmManager and the Scheduled Service Pattern
- PowerManager and WakeLocks
- JobScheduler
- Accessing Location-Based Services
- The Fused Location Provider
- Working with the Clipboard
- Telephony
- Working With SMS
- NFC
- Device Administration
- Basic Use of Sensors
- Printing and Document Generation
- Basic Bluetooth RFCOMM

- Dealing with Different Hardware

Integration and Introspection

- Writing and Using Parcelables
- Responding to URLs
- App Shortcuts
- PackageManager Tricks
- Remote Services and the Binding Pattern
- Advanced Manifest Tips
- Miscellaneous Integration Tips
- Replacing App Code Dynamically

Other Tools

- Android Studio Dialogs and Editors
- Advanced Emulator Capabilities
- Lint and the Support Annotations
- Inspecting Layouts
- Screenshots and Screencasts
- ADB Tips and Tricks
- Stetho
- Finding CPU Bottlenecks
- Finding Memory Leaks

Tuning Android Applications

- Issues with Speed
- Finding CPU Bottlenecks
- NDK
- Improving CPU Performance in Java
- Finding and Eliminating Jank
- Issues with Bandwidth
- Focus On: TrafficStats
- Measuring Bandwidth Consumption
- Being Smarter About Bandwidth
- Issues with Application Heap
- Finding Memory Leaks
- Issues with System RAM
- Issues with Battery Life

- Other Power Measurement Options
- Sources of Power Drain
- Addressing Application Size Issues

Miscellaneous Topics

- Crash Reporting with ACRA
- In-App Diagnostics
- Anti-Patterns

Widget Catalog

- AdapterViewFlipper
- CalendarView
- DatePicker
- ExpandableListView
- SeekBar
- SlidingDrawer
- StackView
- TabHost
- TimePicker
- ViewFlipper

Device Catalog

- Chrome and Chrome OS
- Android Things Basics
- BlackBerry
- Google TV
- Amazon Fire TV
- Samsung DeX

Appendices

- Appendix A: CWAC Libraries
- Appendix B: O Developer Preview
- Appendix C: Community Theater and the Appinars

About the Updates

This book is updated frequently, typically every 6-8 weeks.

Each release has notations to show what is new or changed compared with the immediately preceding release:

- The Table of Contents shows sections with changes in bold-italic font
- Those sections have changebars on the right to denote specific paragraphs that are new or modified

What's New in Version 8.10?

For those of you who have read previous editions of this book, here are some of the highlights of what is new in the prose in Version 8.10.

This update:

- Adds a new chapter on authenticating the user against the device, including through fingerprints
- Adds a new chapter on working with the Android keystore, particularly for encrypting data with keys backed by device authentication, including through fingerprints
- Migrates some more material out of the Android 8.0 appendix into mainstream chapters; what remains will stick around as an appendix for the foreseeable future
- Begins a mass migration away from native fragments to the fragments backport, amid rumors that native fragments will be deprecated in Android P
- Drops the chapter on integrating a JVM-based scripting language, as the chapter was too old, and embedding a language interpreter raises security issues
- Drops the chapter on implementing a plugin-based system, as the chapter was too old (though this chapter may be revisited in the future)
- Fixes a variety of errata

Warescription

You (hopefully) are reading this digital book by means of a Warescription.

The Warescription entitles you, for the duration of your subscription, to digital editions of this book and its updates, in PDF, EPUB, and Kindle (MOBI/KF8) formats. You also have access to a version of the book as its own Android APK file, complete with high-speed full-text searching. You also have access to other titles that CommonsWare may publish during that subscription period.

Each subscriber gets personalized editions of all editions of each title. That way, your books are never out of date for long, and you can take advantage of new material as it is made available. For example, when new releases of the Android SDK are made available, this book will be quickly updated to be accurate with changes in the APIs.

However, you can only download the books while you have an active Warescription. There is a grace period after your Warescription ends: you can still download the book until the next book update comes out after your Warescription ends. After that, you can no longer download the book. Hence, **please download your updates as they come out**. You can find out when new releases of this book are available via:

1. The CommonsWare Twitter feed
2. The CommonsBlog
3. The Warescription newsletter, which you can subscribe to off of your Warescription page
4. Just check back on the Warescription site every month or two

Subscribers also have access to other benefits, including:

- "Office hours" — online chats to help you get answers to your Android application development questions. You will find a calendar for these on your Warescription page.
- A Stack Overflow "bump" service, to get additional attention for a question that you have posted there that does not have an adequate answer.
- A discussion board for asking arbitrary questions about Android app development

About the APK Edition

In addition to classic digital book formats (PDF, EPUB, MOBI/Kindle), this book is available as an Android app, in the form of an APK file. This app has an integrated

digital book reader, showing you the same contents as you would find in the EPUB version of the book. However, it has a few features that are unique.

First, it has a very fast full-text-search index built in. You can quickly search for keywords, class names, and the like, with sub-second response time on most Android hardware. You can even use boolean search clauses (e.g., search on `encryption OR decryption`).

Second, it has Community Theater, where you can view appinars, or app-based training modules. These are presentations, complete with slides, videos, screencasts, source code, and more. Through Community Theater, you can view available appinars, download those of interest, and watch them when you want.

The APK edition of the book reader works on Android 4.0.3 and higher, though the Community Theater portion only works on Android 4.4 and higher.

Installation instructions for the APK edition can be found on the CommonsWare Web site. Details about using Community Theater can be found in an appendix of this book.

Book Bug Bounty

Find a problem in the book? Let CommonsWare know!

Be the first to report a unique concrete problem in the current digital edition, and CommonsWare will extend your Warescription by six months as a bounty for helping CommonsWare deliver a better product.

By "concrete" problem, we mean things like:

1. Typographical errors
2. Sample applications that do not work as advertised, in the environment described in the book
3. Factual errors that cannot be open to interpretation

By "unique", we mean ones not yet reported. Be sure to check the book's errata page, though, to see if your issue has already been reported. One coupon is given per email containing valid bug reports.

We appreciate hearing about "softer" issues as well, such as:

1. Places where you think we are in error, but where we feel our interpretation is reasonable
2. Places where you think we could add sample applications, or expand upon the existing material
3. Samples that do not work due to "shifting sands" of the underlying environment (e.g., changed APIs with new releases of an SDK)

However, those "softer" issues do not qualify for the formal bounty program.

The Book Bug Bounty also extends to the appinars that you view in the Community Theater portion of the APK edition of the book. Typos and similar concrete issues in an appinar will qualify. Be sure to point out which appinar it is and what slide (or code, screenshot, video, etc.) has the problem.

In addition, the Book Bug Bounty covers reproducible bugs in the APK itself. If you are having problems using the APK, due to crashes or some other problem, be sure to let us know, with sufficient steps to reproduce the problem (including information about the device that you are using, such as the Android OS version).

Questions about the bug bounty, or problems you wish to report for bounty consideration, should be sent to bounty@commonsware.com.

Source Code and Its License

The source code samples shown in this book are available for download from the book's GitHub repository. All of the Android projects are licensed under the Apache 2.0 License, in case you have the desire to reuse any of it.

If you wish to use the source code from the GitHub repository, please follow the instructions on that repository's home page for details of how to use the projects in various development environments, notably Android Studio.

Copying source code directly from the book, in the PDF editions, works best with Adobe Reader, though it may also work with other PDF viewers. Some PDF viewers, for reasons that remain unclear, foul up copying the source code to the clipboard when it is selected.

Creative Commons and the Four-to-Free (42F) Guarantee

Each CommonsWare book edition will be available for use under the Creative Commons Attribution-Noncommercial-ShareAlike 3.0 license as of the fourth anniversary of its publication date, or when 4,000 copies of the edition have been sold, whichever comes first. That means that, once four years have elapsed (perhaps sooner!), you can use this prose for non-commercial purposes. That is our Four-to-Free Guarantee to our readers and the broader community. For the purposes of this guarantee, new Warescriptions and renewals will be counted as sales of this edition, starting from the time the edition is published.

This edition of this book will be available under the aforementioned Creative Commons license on *1 February 2022*. Of course, watch the CommonsWare Web site, as this edition might be relicensed sooner based on sales.

For more details on the Creative Commons Attribution-Noncommercial-ShareAlike 3.0 license, visit the Creative Commons Web site

Note that future editions of this book will become free on later dates, each four years from the publication of that edition or based on sales of that specific edition. Releasing one edition under the Creative Commons license does not automatically release *all* editions under that license.

Acknowledgments

I would like to thank the Android team, not only for putting out a good product, but for invaluable assistance on the Android Google Groups and Stack Overflow.

I would also like to thank the thousands of readers of past editions of this book, for their feedback, bug reports, and overall support.

Of course, thanks are also out to the overall Android ecosystem, particularly those developers contributing their skills to publish libraries, write blog posts, answer support questions, and otherwise contribute to the strength of Android.

Portions of this book are reproduced from work created and shared by the Android Open Source Project and used according to terms described in the Creative Commons 2.5 Attribution License.

Core Chapters

Key Android Concepts

No doubt, you are in a hurry to get started with Android application development. After all, you are reading this book, aimed at busy coders.

However, before we dive into getting tools set up and starting in on actual programming, it is important that we "get on the same page" with respect to several high-level Android concepts. This will simplify further discussions later in the book.

Android Applications

This book is focused on writing Android applications. An application is something that a user might install from the Play Store or otherwise download to their device. That application should have some user interface, and it might have other code designed to work in the background (multi-tasking).

This book is not focused on modifications to the Android firmware, such as writing device drivers. For that, you will need to seek other resources.

This book assumes that you have some hands-on experience with Android devices, and therefore you are familiar with buttons like HOME and BACK, the built-in Settings application, the concept of a home screen and launcher, and so forth. If you have never used an Android device, you are strongly encouraged to get one (new or used) and spend some time with it before starting in on learning Android application development.

Programming Language

The vast majority of Android applications are written exclusively in Java. Hence, that is what this book will spend most of its time on and will demonstrate with a seemingly infinite number of examples.

However, there are other options:

- You can write parts of the app in C/C++, for performance gains, porting over existing code bases, etc.
- You can write an entire app in C/C++, mostly for games using OpenGL for 3D animations
- You can write the guts of an app in HTML, CSS, and JavaScript, using tools to package that material into an Android application that can be distributed through the Play Store and similar venues
- And so on

Some of this will be covered later in the book, but the vast majority of this book is focused on Java-based app development.

The author assumes that you know Java at this point. If you do not, you will need to learn Java before you go much further. You do not need to know *everything* about Java, as Java is vast. Rather, focus on:

- Language fundamentals (flow control, etc.)
- Classes and objects
- Methods and data members
- Public, private, and protected
- Static and instance scope
- Exceptions
- Threads
- Collections
- Generics
- File I/O
- Reflection
- Interfaces

The links are to Wikibooks material on those topics, though there are countless other Java resources for you to consider.

Google also supports Kotlin as a programming language for Android apps. Kotlin can be used as a replacement for Java. While Kotlin has plenty of benefits, it is also a relatively new programming language. This book is focused on the Android SDK, more so than on Java (or Kotlin), and so regardless of which of those two languages you use, the material in this book will be relevant. This book's examples are mostly in Java, due to that being the dominant Android app development language today.

Components

When you first learned Java — whether that was yesterday or back when dinosaurs roamed the Earth — you probably started off with something like this:

```
class SillyApp {
    public static void main(String[] args) {
        System.out.println("Hello, world!");
    }
}
```

In other words, the entry point into your application was a `public static void` method named `main()` that took a `String` array of arguments. From there, you were responsible for doing whatever was necessary.

However, there are other patterns used elsewhere in Java. For example, you do not usually write a `main()` method when writing a Java servlet. Instead, you extend a particular class supplied by a framework (e.g., `HttpServlet`) to create a component, then write some metadata that enumerates your components and tell the framework when and how to use them (e.g., `WEB.XML`).

Android apps are closer in spirit to the servlet approach. You will not write a `public static void main()` method. Instead, you will create subclasses of some Android-supplied base classes that define various application components. In addition, you will create some metadata that tells Android about those subclasses.

There are four types of components, all of which will be covered extensively in this book:

Activities

The building block of the user interface is the *activity*. You can think of an activity as being the Android analogue for the window or dialog in a desktop application, or the page in a classic Web app. It represents a chunk of your user interface and, in

some cases, a discrete entry point into your app (i.e., a way for other apps to link to your app).

Normally, an activity will take up most of the screen, leaving space for some "chrome" bits like the clock, signal strength indicators, and so forth.

However, bear in mind that on some devices, the user will be able to work with more than one activity at a time, such as split-screen mode on a phone or tablet. So, while it is easy to think of activities as being equivalent to the screen, just remember that this is a simplification, and that reality is more complicated (as reality often is).

Services

Activities are short-lived and can be shut down at any time, such as when the user presses the BACK button. *Services*, on the other hand, are designed to keep running, if needed, independent of any activity, for a moderate period of time. You might use a service for checking for updates to an RSS feed, or to play back music even if the controlling activity is no longer operating. You will also use services for scheduled tasks (akin to Linux or macOS "cron jobs") and for exposing custom APIs to other applications on the device, though the latter is a relatively advanced capability.

Content Providers

Content providers provide a level of abstraction for any data stored on the device that is accessible by multiple applications. The Android development model encourages you to make your own data available to other applications, as well as your own — building a content provider lets you do that, while maintaining a degree of control over how your data gets accessed.

So, for example, if you have a PDF file that you downloaded on behalf of the user, and you want to allow the user to view that PDF file, you might create a content provider to make that PDF file available to other apps. You can then start up an activity that will be able to view that PDF, where Android and the user will determine what PDF-viewing activity handles that request.

Broadcast Receivers

The system, or applications, will send out *broadcasts* from time to time, for everything from the battery getting low, to when the screen turns off, to when

connectivity changes from WiFi to mobile data. A broadcast receiver can arrange to listen for these broadcasts and respond accordingly.

Widgets, Containers, and Resources

Most of the focus on Android application development is on the UI layer and activities. Most Android activities use what is known as "the widget framework" for rendering their user interface, though you are welcome to use the 2D (`Canvas`) and 3D (OpenGL) APIs as well for more specialized GUIs.

In Android terms, a *widget* is the "micro" unit of user interface. Fields, buttons, labels, lists, and so on are all widgets. Your activity's UI, therefore, is made up of one or more of these widgets. This is a common approach in most UI toolkits, and so most likely you have already worked with buttons, labels, fields, and similar sorts of widgets somewhere else previously.

If you have more than one widget — which is fairly typical — you will need to tell Android how those widgets are organized on the screen. To do that, you will use various container classes referred to as *layout managers*. These will let you put things in rows, columns, or more complex arrangements as needed.

To describe how the containers and widgets are connected, you will typically create a *layout resource file*. *Resources* in Android refer to things like images, strings, and other material that your application uses but is not in the form of some programming language source code. UI layouts are another type of resource. You will create these layouts either using a structured tool, such as an IDE's drag-and-drop GUI builder, or by hand in XML form.

Sometimes, your UI will work across all sorts of devices: phones, tablets, televisions, etc. Sometimes, your UI will need to be tailored for different environments. You will be able to put resources into *resource sets* that indicate under what circumstances those resources can be used (e.g., use these for normal-sized screens, but use those for larger screens).

We will be examining all of these concepts, in much greater detail, as we get deeper into the book.

Apps and Packages

Given a bucket of source code and a basket of resources, the Android build tools will give you an application as a result. The application comes in the form of an *APK file*. It is that APK file that you will upload to the Play Store or distribute by other means.

Each Android application has a package name, also referred to as an application ID. A package name must fulfill three requirements:

1. It must be a valid Java package name, as some Java source code will be generated by the Android build tools in this package
2. No two applications can exist on a device at the same time with the same application ID
3. No two applications can be uploaded to the Play Store having the same application ID

When you create your Android project — the repository of that source code and those resources — you will declare what package name is to be used for your app. Typically, you will pick a package name following the Java package name "reverse domain name" convention (e.g., `com.commonsware.android.foo`). That way, the domain name system ensures that your package name prefix (`com.commonsware`) is unique, and it is up to you to ensure that the rest of the package name distinguishes one of your apps from any other.

Android Devices

There are well in excess of one billion Android devices in use today, representing thousands of different models from dozens of different manufacturers. Android itself has evolved since Android 1.0 in 2008. Between different device types and different Android versions, many a media pundit has lobbed the term "fragmentation" at Android, suggesting that creating apps that run on all these different environments is impossible.

In reality, it is not that bad. Some apps will have substantial trouble, but most apps will work just fine if you follow the guidance presented in this book and in other resources.

Types

Android devices come in all shapes, sizes, and colors. However, there are three dominant "form factors":

- the phone
- the tablet
- the notebook (mostly, these run Chrome OS, which has some support for Android apps)

Beyond that, there are several less-common form factors

- the television (TV)
- the wearable (smart watches, etc.)
- the desktop (a device designed to be plugged into a monitor, keyboard, and mouse)

You will often hear developers and pundits refer to these form factors, and this book will do so from time to time as well. However, it is important that you understand that Android has no built-in concept of a device being a "phone" or a "tablet" or a "TV". Rather, Android distinguishes devices based on capabilities and features. So, you will not see an `isPhone()` method anywhere, though you can ask Android:

- what is the screen size?
- does the device have telephony capability?
- etc.

Similarly, as you build your applications, rather than thinking of those form factors, focus on what capabilities and features you need. Not only will this help you line up better with how Android wants you to build your apps, but it will make it easier for you to adapt to other form factors that will come about such as:

- airplane seat-back entertainment centers
- in-car navigation and entertainment devices
- and so on

The Emulator

While there are ~2 billion Android devices representing ~10,000 device models, probably you do not have one of each model. You may only have a single piece of

Android hardware. And if you do not even have that, you most certainly will want to acquire one before trying to publish an Android app.

To help fill in the gaps between the devices you have and the devices that are possible, the Android developer tools ship an *emulator*. The emulator behaves like a piece of Android hardware, but it is a program you run on your development machine. You can use this emulator to emulate many different devices, with different screen sizes and Android OS versions, by creating one or more Android virtual devices, or *AVDs*.

In an upcoming chapter, we will discuss how you install the Android developer tools and how you will be able to create these AVDs and run the emulator.

OS Versions and API Levels

Android has come a long way since the early beta releases from late 2007. Each new Android OS version adds more capabilities to the platform and more things that developers can do to exploit those capabilities.

Moreover, the core Android development team tries very hard to ensure forwards and backwards compatibility. An app you write today should work unchanged on future versions of Android (forwards compatibility), albeit perhaps missing some features or working in some sort of "compatibility mode". And there are well-trod paths for how to create apps that will work both on the latest and on previous versions of Android (backwards compatibility).

To help us keep track of all the different OS versions that matter to us as developers, Android has *API levels*. A new API level is defined when an Android version ships that contains changes that affect developers. When you create an emulator AVD to test your app, you will indicate what API level that emulator should emulate. When you distribute your app, you will indicate the oldest API level your app supports, so the app is not installed on older devices.

At the time of this writing, the API levels of significance to most Android developers are:

- API Level 19 (Android 4.4)
- API Level 21 (Android 5.0)
- API Level 22 (Android 5.1)
- API Level 23 (Android 6.0)
- API Level 24 (Android 7.0)

- API Level 25 (Android 7.1)

Here, "of significance" refers to API levels that have a reasonable number of Android devices — 5% or more, as reported by the "Platform Versions" dashboard chart.

The latest version of Android is 8.1, API Level 27.

Note that API Level 20 was used for the version of Android 4.4 running on the first-generation Android Wear devices. Unless you are specifically developing apps for Wear, you will not be worrying much about API Level 20.

Dalvik and ART

In terms of Android, Dalvik and ART are virtual machines (VM)s. Virtual machines are used by many programming languages, such as Java, Perl, and Smalltalk. Dalvik and ART are designed to work much like a Java VM, but optimized for embedded Linux environments.

Primarily, the difference between the two is that ART is used on Android 5.0 and higher, while Dalvik was used on older devices. In truth, the story is more complicated than this, but this will do for now.

So, what really goes on when somebody writes an Android application is:

1. Developers write Java-syntax source code, leveraging class libraries published by the Android project and third parties.
2. Developers compile the source code into Java VM bytecode, using the `javac` compiler that comes with the Java SDK.
3. Developers translate the Java VM bytecode into Dalvik VM bytecode, which is packaged with other files into a ZIP archive with the `.apk` extension (the APK file).
4. An Android device or emulator runs the APK file, causing the bytecode to be executed by an instance of a Dalvik or ART VM.

From your standpoint, most of this is hidden by the build tools. You pour Java source code into the top, and the APK file comes out the bottom.

However, there will be places from time to time where the differences between the Dalvik VM and the traditional Java VM will affect application developers, and this book will point out some of them where relevant.

Processes and Threads

When your application runs, it will do so in its own process. This is not significantly different than any other traditional operating system. Part of Dalvik's magic is making it possible for many processes to be running many Android applications at one time without consuming ridiculous amounts of RAM.

Android will also set up a batch of threads for running your app. The thread that your code will be executed upon, most of the time, is variously called the "main application thread" or the "UI thread". You do not have to set it up, but, as we will see later in the book, you will need to pay attention to what you do and do not do on that thread. You are welcome to fork your own threads to do work, and that is fairly common, though in some places Android handles that for you behind the scenes.

Don't Be Scared

Yes, this chapter threw a lot of terms at you. We will be going into greater detail on all of them in this book. However, Android is like a jigsaw puzzle with lots of interlocking pieces. To be able to describe one concept in detail, we will need to at least reference some of the others. Hence, this chapter was meant to expose you to terms, in hopes that they will sound vaguely familiar as we dive into the details.

Choosing Your Development Toolchain

Before you go much further in your Android endeavors (or possibly endeavours, depending upon your preferred spelling), you will need to determine what toolchain you will use to build your Android applications.

Android Studio

The current Google-backed Android IDE is Android Studio. Based on IntelliJ IDEA, Android Studio is the new foundation of Google's efforts to give Android developers top-notch development tools.

The next chapter contains a section with instructions on how to set up Android Studio.

Note, though, that Android Studio requires a fairly powerful development machine to work well: a fast CPU, lots of RAM (8GB or more), and an SSD are all strongly recommended.

Eclipse

Eclipse is also a popular IDE, particularly for Java development. Eclipse was Google's original IDE for Android development, by means of the Android Developer Tools (ADT) add-in, which gives the core of Eclipse awareness of Android. The ADT add-in, in essence, takes regular Eclipse operations and extends them to work with Android projects.

Note, though, that Google has discontinued maintenance of ADT. The Eclipse Foundation is setting up the "Andmore" project to try to continue work on allowing Eclipse to build Android apps. This book does not cover the Andmore project at this time, and developers are **strongly** encouraged to not use the ADT-enabled Eclipse from Google.

IntelliJ IDEA

While Android Studio is based on IntelliJ IDEA, you can still use the original IntelliJ IDEA for Android app development. A large subset of the Android Studio capabilities are available in the Android plugin for IDEA. Plus, the commercial IDEA Ultimate Edition will go beyond Android Studio in many areas outside of Android development.

In particular, if you are looking for "the one true IDE" that you can use for Android and non-Android projects, you should consider IntelliJ IDEA. Android Studio is nice, but it is mostly for Android projects.

Command-Line Builds via Gradle

And, of course, you do not need to use an IDE at all. While this may sound sacrilegious to some, IDEs are not the only way to build applications. Much of what is accomplished via an IDE can be accomplished through command-line equivalents, meaning a shell and an editor is all you truly need.

The recommended way to build Android apps outside of an IDE is by means of Gradle. Google has published a Gradle plugin that teaches Gradle how to build Android apps. Android Studio itself uses Gradle for its builds, so a single build configuration (e.g., `build.gradle` files) can be used both from an IDE and from a build automation tool like a continuous integration server.

An upcoming chapter gets into more about what Gradle (and the Android Gradle Plugin) are all about.

Yet Other Alternatives

Other IDEs have their equivalents of the ADT, albeit with minimal assistance from Google. For example, NetBeans has support via the NBAndroid add-on, and reportedly this has advanced substantially in the past few years.

You will also hear reference to using Apache Ant for doing command-line builds of Android apps. This has been supplanted by the Android Gradle Plugin at this time, and there is little support for Apache Ant anymore. Newcomers to Android are encouraged to not invest time in new work with Apache Ant for Android development projects.

IDEs… And This Book

You are encouraged to use Android Studio as you work through this book. You are welcome to use another IDE if you wish. You are even welcome to skip the IDE outright and just use an editor.

This book is focused primarily on demonstrating Android capabilities and the APIs for exploiting those capabilities. Hence, the sample code will work with any IDE. However, this book will cover some Android Studio-specific instructions, since that is the predominant Android IDE in use today.

What We Are Not Covering

In the beginning (a.k.a., 2007), we were lucky to have any means of creating an Android app.

Nowadays, there seems to be no end to the means by which we can create an Android app.

There are a few of these "means", though, that are specifically out of scope for this book.

App Inventor

You may also have heard of a tool named App Inventor and wonder where it fits in with all of this.

App Inventor was originally created by an education group within Google, as a means of teaching students how to think about programming constructs (branches, loops, etc.) and create interesting output (Android apps) without classic programming in Java or other syntax-based languages. App Inventor is purely drag-and-drop, both of widgets *and application logic*, the latter by means of "blocks" that snap together to form logic chains.

App Inventor was donated by Google to MIT, which has recently re-opened it to the public.

However, App Inventor is a closed system — at the present time, it does not somehow generate Java code that you can later augment. That limits you to whatever App Inventor is natively capable of doing, which, while impressive in its own right, offers a small portion of the total Android SDK capabilities.

App Generators

There are a seemingly infinite number of "app generators" available as online services. These are designed mostly for creating apps for specific vertical markets, such as apps for restaurants or apps for grocers. The resulting apps are mostly "brochure-ware", with few capabilities beyond a mobile Web site, yet still requiring the user to find, download, and install the app. Few of these generators provide the source code to the generated app, to allow the apps to be customized beyond what the generator generates.

Tutorial #1 - Installing the Tools

Now, let us get you set up with the pieces and parts necessary to build an Android app.

NOTE: The instructions presented here are accurate as of the time of this writing. However, the tools change rapidly, and so these instructions may be out of date by the time you read this. Please refer to the Android Developers Web site for current instructions, using this as a base guideline of what to expect.

But First, Some Notes About Android's Emulator

The Android tools include an emulator, a piece of software that pretends to be an Android device. This is very useful for development — not only does it mean you can get started on Android without a device, but the emulator can help test device configurations that you do not own.

There are two types of emulator: x86 and ARM. These are the two major types of CPUs used for Android devices. You *really* want to be able to use the x86 emulator, as the ARM emulator is extremely slow.

However, to use the x86 emulator, your development machine must have things set up properly first. Linux users need KVM, while Mac and Windows users need the "Intel Hardware Accelerated Execution Manager" (a.k.a., HAXM).

Also, this only works for certain CPU architectures, ones that support virtualization in hardware:

- Intel Virtualization Technology (VT, VT-x, vmx) extensions
- AMD Virtualization (AMD-V, SVM) extensions (Linux only)

Those virtualization extensions must also be enabled in your device's BIOS, and other OS-specific modifications may be required.

Also, at least for newer API levels, your CPU must support SSSE3 extensions, though the details of this requirement are not documented as of October 2017.

Part of the Android Studio installation process will try to set you up to be able to use the x86 emulator. Make note of any messages that you see in the installation wizard regarding "HAXM" (or, if you are running Linux, KVM), as those will be important later.

Step #1: Checking Your Hardware

Compiling and building an Android application, on its own, can be a hardware-intensive process, particularly for larger projects. Beyond that, your IDE and the Android emulator will stress your development machine further. Of the two, the emulator poses the bigger problem.

The more RAM you have, the better. 8GB or higher is a very good idea if you intend to use an IDE and the emulator together. If you can get an SSD for your data storage, instead of a conventional hard drive, that too can dramatically improve the IDE performance.

A faster CPU is also a good idea. The Android SDK emulator, as of 2016, supports CPUs with multiple cores — previously, it only supported a single core. However, other processes on your development machine will be competing with the emulator for CPU time, and so the faster your CPU is, the better off you will be. Ideally, your CPU has 2 to 4 cores, each 2.5GHz or faster at their base speed.

Beyond that, to use the x86 emulator — the emulator that runs well — you need a CPU with certain features:

Development OS	CPU Requirements
Windows	an Intel CPU with support for VT-x, EM64T, and "Execute Disable" (XD)
Mac	any
Linux	an Intel CPU with support for VT-x, EM64T, and "Execute Disable" (XD), or an AMD CPU with support for AMD-V

If your CPU does not meet those requirements, you will want to have 1+ Android devices available to you, so that you can test on hardware.

Also, if you are running Windows or Linux, you need to ensure that your computer's BIOS is set up to support Intel's virtualization extensions. Unfortunately, many PC manufacturers disable this by default. The details of how to get into your BIOS settings will vary by PC, but usually it involves rebooting your computer and pressing some function key on the initial boot screen. In the BIOS settings, you are looking for references to "virtualization" or "VT-x". Enable them if they are not already enabled. macOS machines come with virtualization extensions pre-enabled.

Step #2: Setting Up Java and 32-Bit Linux Support

When you write Android applications, you typically write them in Java source code. That Java source code is then turned into the stuff that Android actually runs (Dalvik bytecode in an APK file).

Android Studio, starting with version 2.2, ships with its own private copy of OpenJDK 8, and it will use that by default. You are welcome to install and use your own JDK if you wish, though ideally it is for Java 8.

If your development OS is Linux, make sure that you can run 32-bit Linux binaries. This may or may not already be enabled in your Linux distro. For example, on Ubuntu 17.10, you may need to run the following to get the 32-bit binary support installed that is needed by the Android build tools:

```
sudo apt-get install libncurses5:i386 libstdc++6:i386 zlib1g:i386
```

Step #3: Install Android Studio

As noted in the previous chapter, there are a few developer tools that you can choose from.

This book's tutorials focus on Android Studio. You are welcome to attempt to use Eclipse, another IDE, or no IDE at all for building Android apps. However, you will need to translate some of the tutorials' IDE-specific instructions to be whatever is needed for your development toolchain of choice.

At the time of this writing, the current production version of Android Studio is 3.0.1, and this book covers that version. If you are reading this in the future, you

may be on a newer version of Android Studio, and there may be some differences between what you have and what is presented here.

You have two major download options. You can get the latest shipping version of Android Studio from the Android Studio download page.

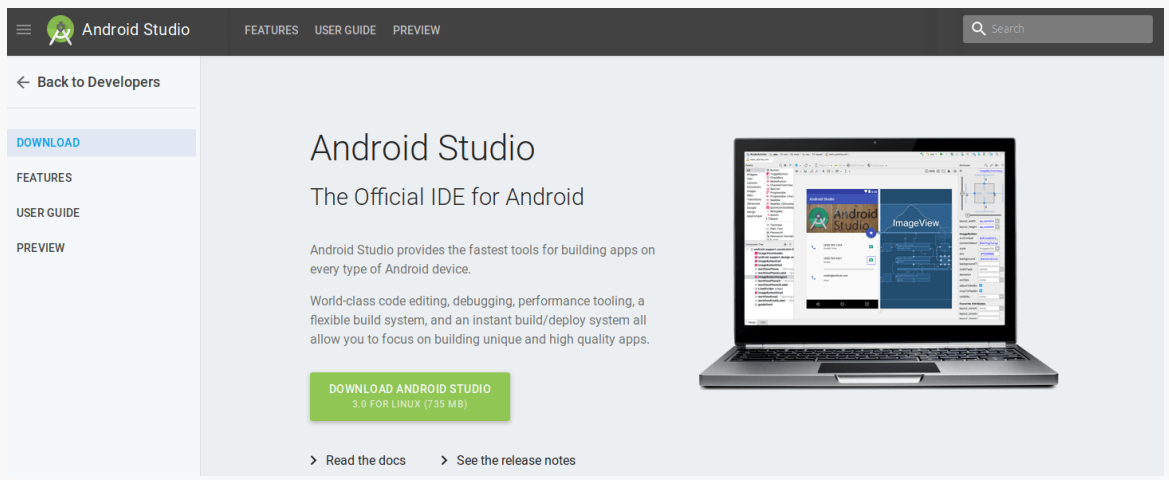

Figure 1: Android Studio Download Page

Or, you can download Android Studio 3.0.1 — the version used in this edition of this book — directly, for:

- Windows
- macOS
- Linux

Windows users can download a self-installing EXE, which will add suitable launch options for you to be able to start the IDE.

macOS users can download a DMG disk image and install it akin to other macOS software, dragging the Android Studio icon into the Applications folder.

Linux users (and power Windows users) can download a ZIP file, then unZIP it to some likely spot on your hard drive. Android Studio can then be run from the `studio` batch file or shell script from your Android Studio installation's `bin/` directory.

Step #4: Install the SDKs and Add-Ons

Next, we need to review what pieces of the Android SDK we have already and perhaps install some new items. To do that, you need to access the SDK Manager.

When you first run Android Studio, you may be asked if you want to import settings from some other prior installation of Android Studio:

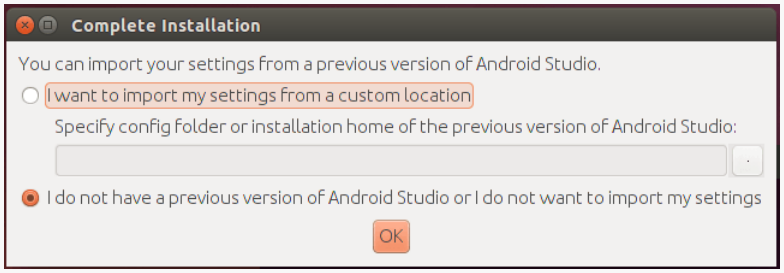

Figure 2: Android Studio First-Run Settings Migration Dialog

For most users, particularly those using Android Studio for the first time, the "I do not have..." option is the correct choice to make.

Then, after a short splash screen and a potentially long "Finding Available SDK Components" progress dialog, you will be taken to the Android Studio Setup Wizard:

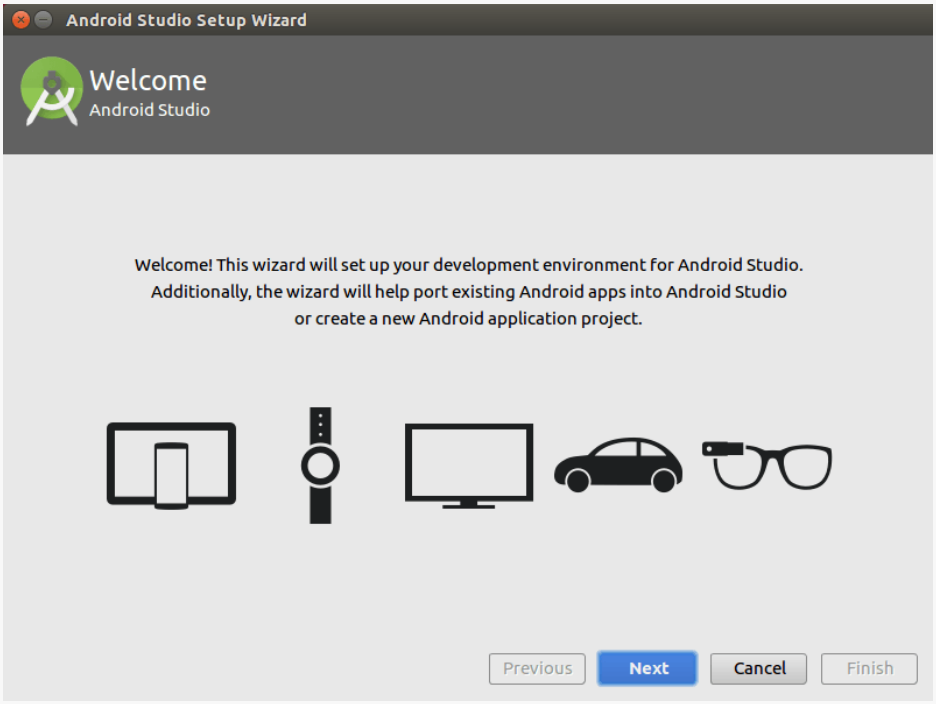

Figure 3: Android Studio Setup Wizard, First Page

Just click "Next" to advance to the second page of the wizard:

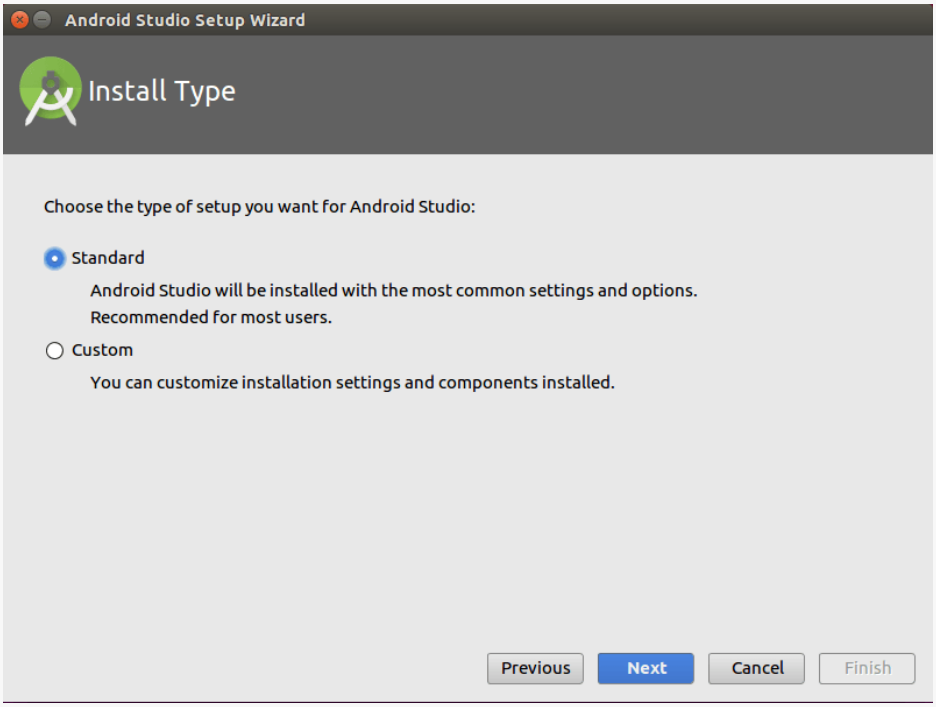

Figure 4: Android Studio Setup Wizard, Second Page

Here, you have a choice between “Standard” and “Custom” setup modes. Most likely, right now, the “Standard” route will be fine for your environment.

If you go the “Standard” route and click “Next”, you should be taken to a wizard page where you can choose your UI theme:

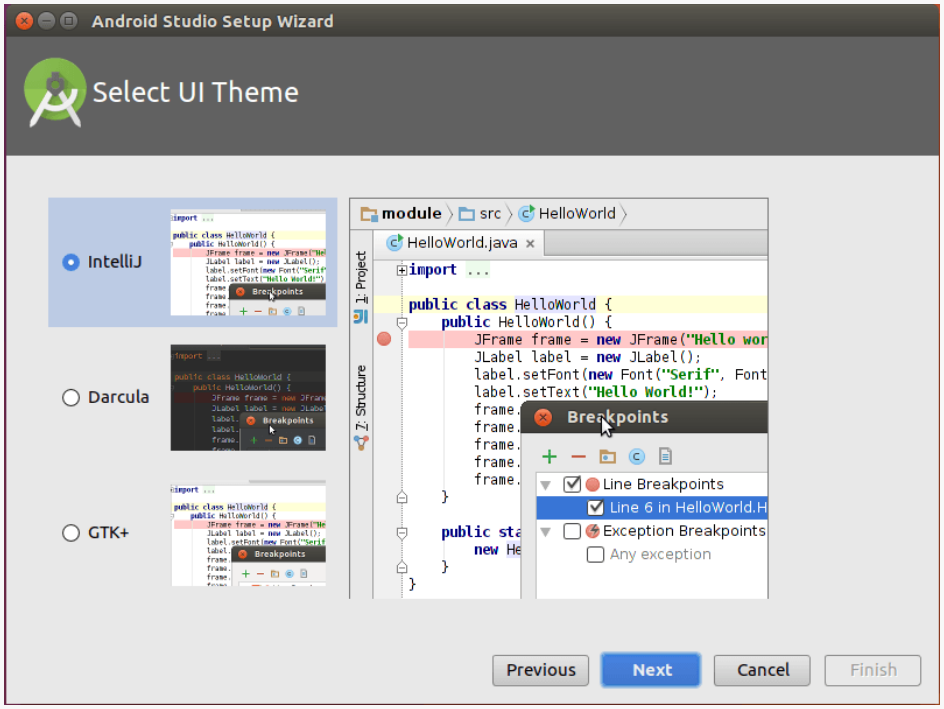

Figure 5: Android Studio Setup Wizard, UI Theme Page

Choose whichever you like, then click Next, to go to a wizard page to verify what will be downloaded and installed:

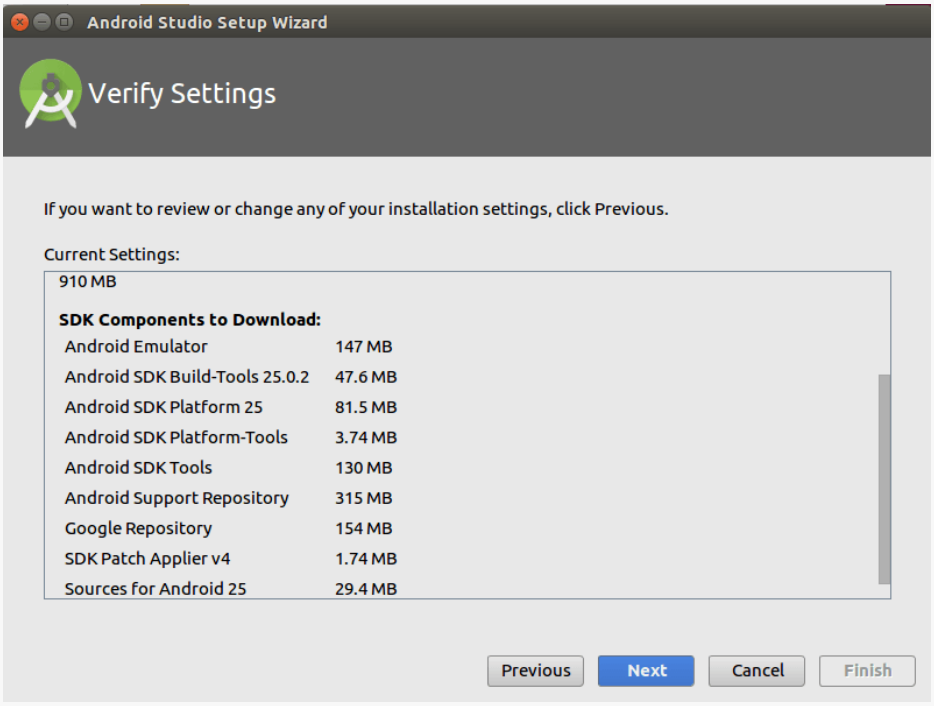

Figure 6: Android Studio Setup Wizard, Verify Settings Page

Clicking Next may take you to a wizard page explaining some information about the Android emulator:

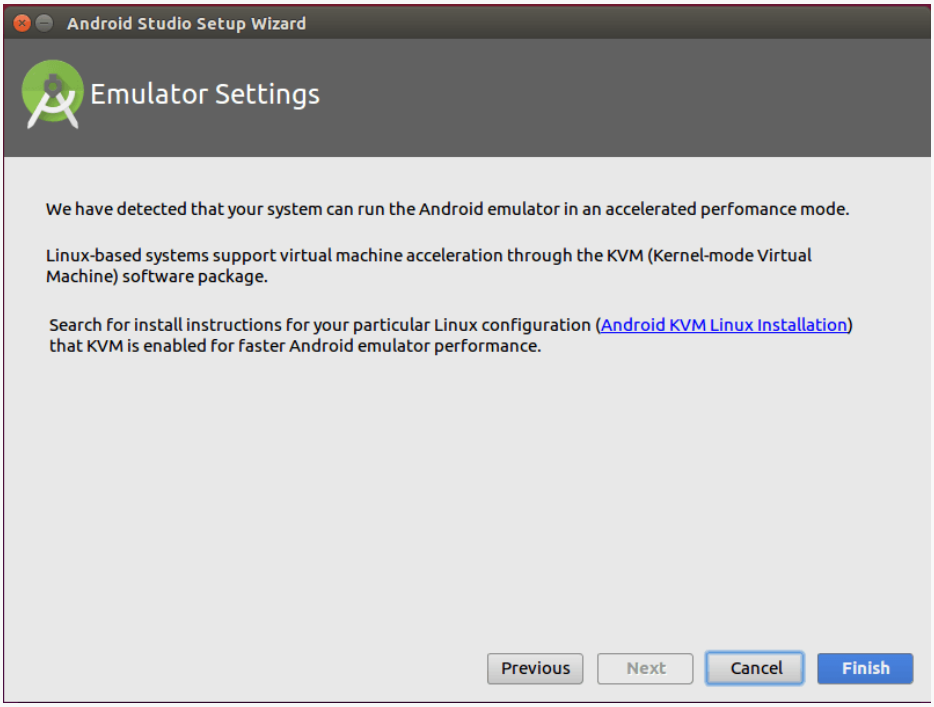

Figure 7: Android Studio Setup Wizard, Emulator Info Page

What is explained on this page may not make much sense to you. That is perfectly normal, and we will get into what this page is trying to say later in the book. Just click "Finish" to begin the setup process. This will include downloading a copy of the Android SDK and installing it into a directory adjacent to where Android Studio itself is installed.

When that is done, after clicking "Finish", Android Studio will busily start downloading stuff to your development machine. If you are running Linux, and your installation crashes with an "Unable to run mksdcard SDK tool" error, go back to Step #2 and set up 32-bit support on your Linux environment.

Clicking "Finish" will then take you to the Android Studio Welcome dialog:

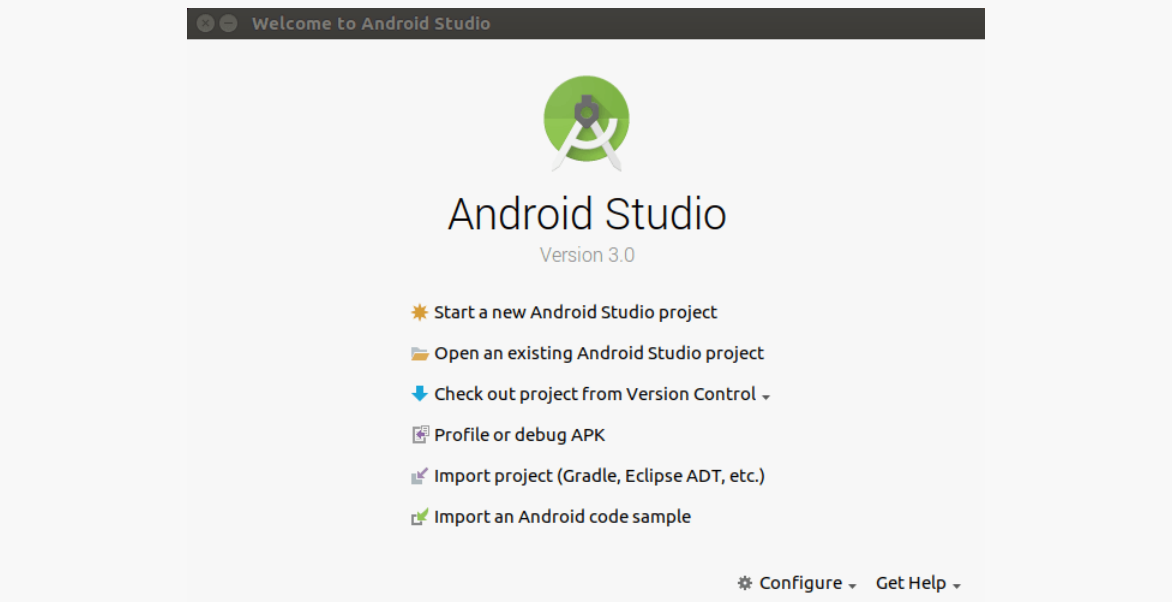

Figure 8: Android Studio Welcome Dialog

Then, in the welcome dialog, click Configure, to bring up a configuration drop-down list:

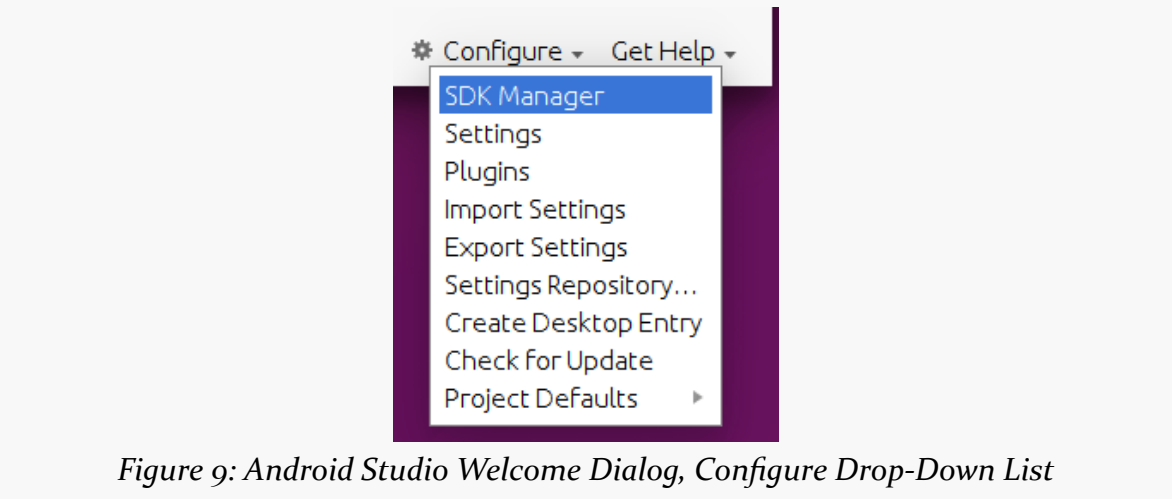

Figure 9: Android Studio Welcome Dialog, Configure Drop-Down List

There, tap on SDK Manager to bring up the SDK Manager.

Using SDK Manager and Updating Your Environment

You should now have the SDK Manager open, as part of the overall default settings for Android Studio:

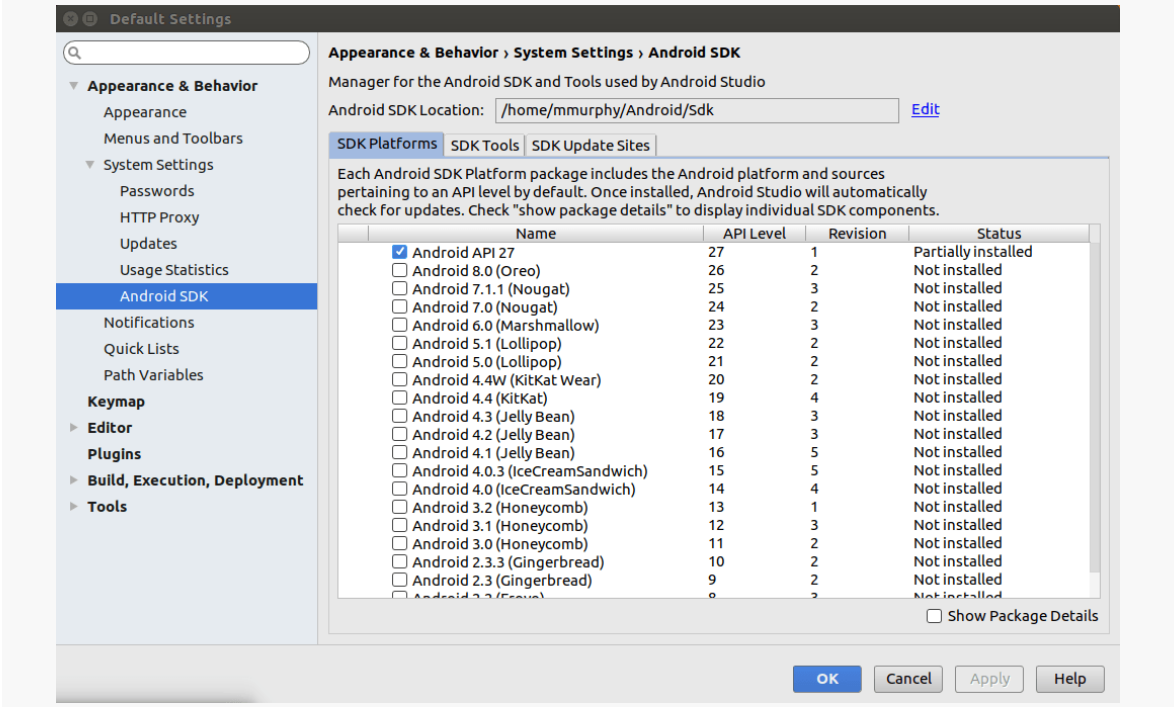

Figure 10: Android SDK Manager, "SDK Platforms" Tab

The "SDK Platforms" tab lists the versions of Android that you can compile against. The latest version of Android (or possibly a preview edition) is usually installed when you set up Android Studio initially. However, for the tutorials, please also check "Android 7.1 (Nougat)" in the list if it is not already checked, and then click the "Apply" button to download and install those versions. You may need to accept a license confirmation dialog as part of this process — review the license, and if you accept it, click Next to begin the download:

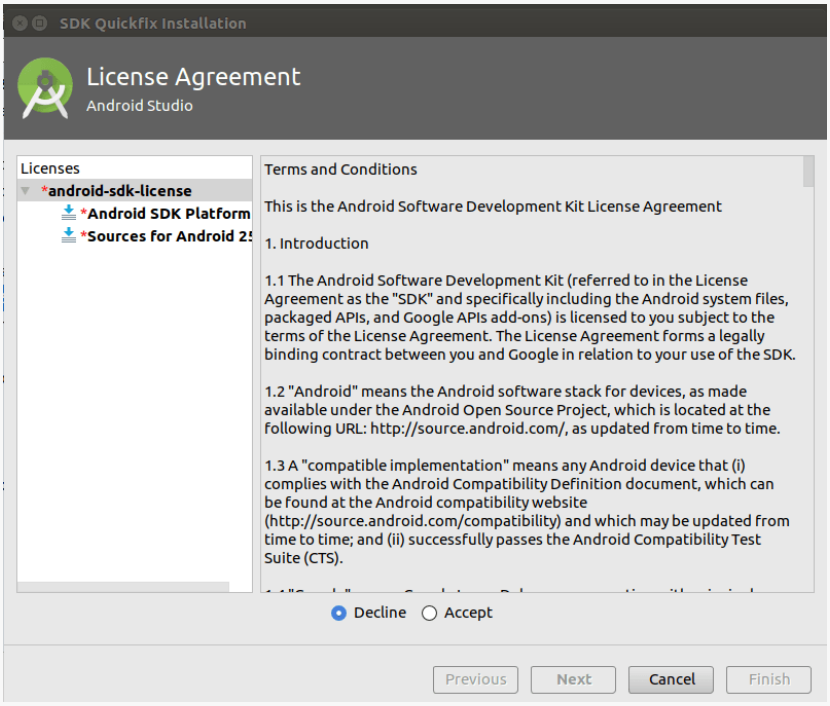

Figure 11: Android SDK Manager, License Confirmation Dialog

When that has completed, you can click "Finish" to close up the download dialog, and then you will be returned to the SDK Manager. Then, you can close up the SDK Manager by clicking the OK button.

In Our Next Episode…

… we will create an Android project that will serve as the basis for all our future tutorials, plus set up our emulator and device.

Android and Projects

When you work on creating an app for Android, you will do so by working in a "project". The project is a directory containing your source code and other files, like images and UI definitions. Your IDE or other build tools will take what is in your project and generate an Android app (APK) as output.

The details of how you get started with a project vary based upon what IDE you are using, so this chapter goes through the various possibilities.

Projects and Android Studio

With Android Studio, to work on a project, you can either create a new project from scratch, you can copy an existing Android Studio project to a new one, or you can import an existing Android project into Android Studio. The following sections will review the steps needed for each of these.

Creating a New Project

You can create a project from one of two places:

- If you are at the initial dialog that you first encountered when you opened Android Studio, choose the "Start a new Android Studio project..." menu item
- If you are inside the Android Studio IDE itself, choose File > New > New Project... from the main menu

This brings up the new-project wizard:

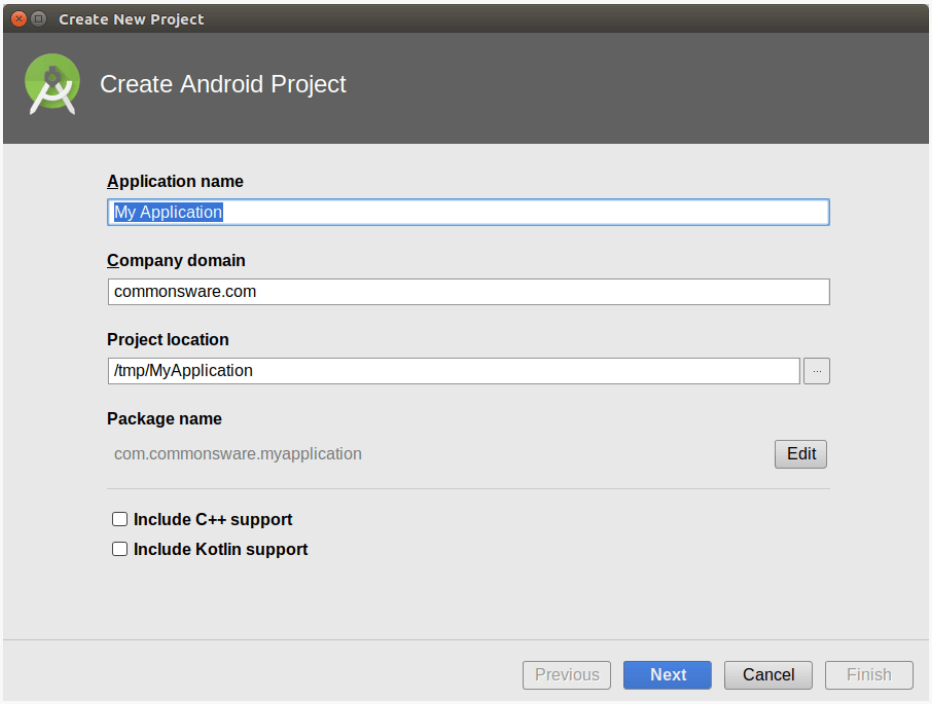

Figure 12: Android Studio Create-Project Wizard, First Page

The first page of the wizard is where you can specify:

- The application name, which is the initial name of your project as seen by the user, in places like your home screen launcher icon and the list of installed applications.
- The package name, which refers to a Java package name (e.g., `com.commonsware.empublite`). This package name will be used for generating some Java source code, and it also is used as a unique identifier of this app, as was mentioned earlier in this book.
- The directory where you want the project files to go
- Whether you know right now if you will be using C++ or not, as part of the Android Native Development Kit (NDK)
- Whether you know right now if you will be using Kotlin or not

Nothing that you choose here is permanent; you can revise everything later on if needed. The most painful to change is the package name, so ideally you choose a good value up front.

By default, the package name will be made up of two pieces:

1. The domain name that you specify in the “Company Domain” field
2. The application name, converted into all lowercase with no spaces or other punctuation

If this is not what you want, click the “Edit” button on the far right side of the proposed package name, which will now allow you to edit the package name directly:

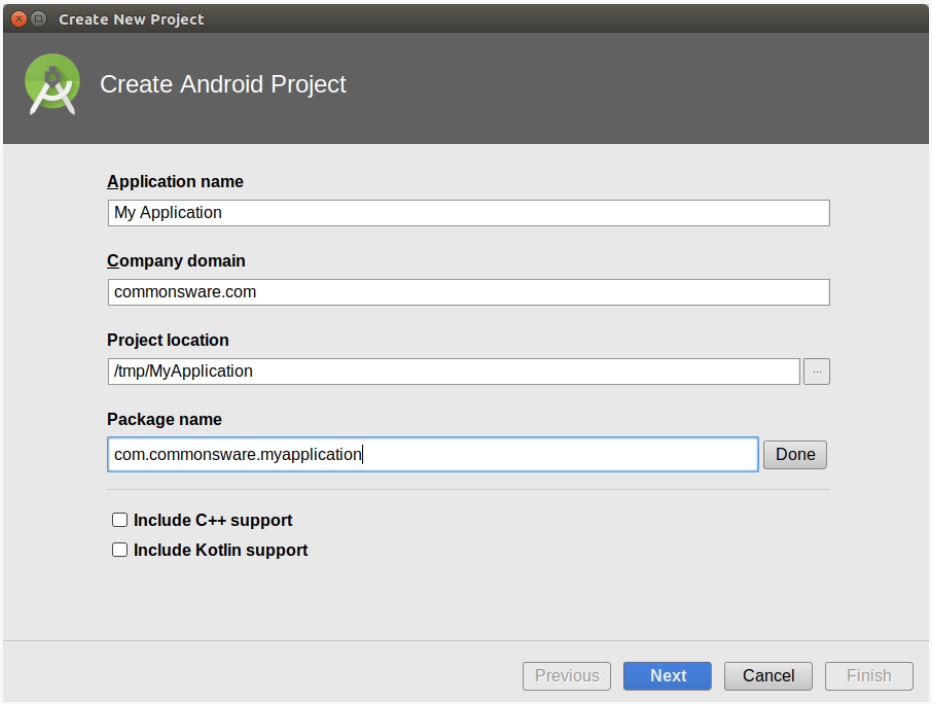

Figure 13: Android Studio Create-Project Wizard, First Page, with Editable Package Name

Clicking “Next” will advance you to a wizard page where you indicate what sort of project you are creating, in terms of intended device type (phones/tablets, TVs, etc.) and minimum required SDK level:

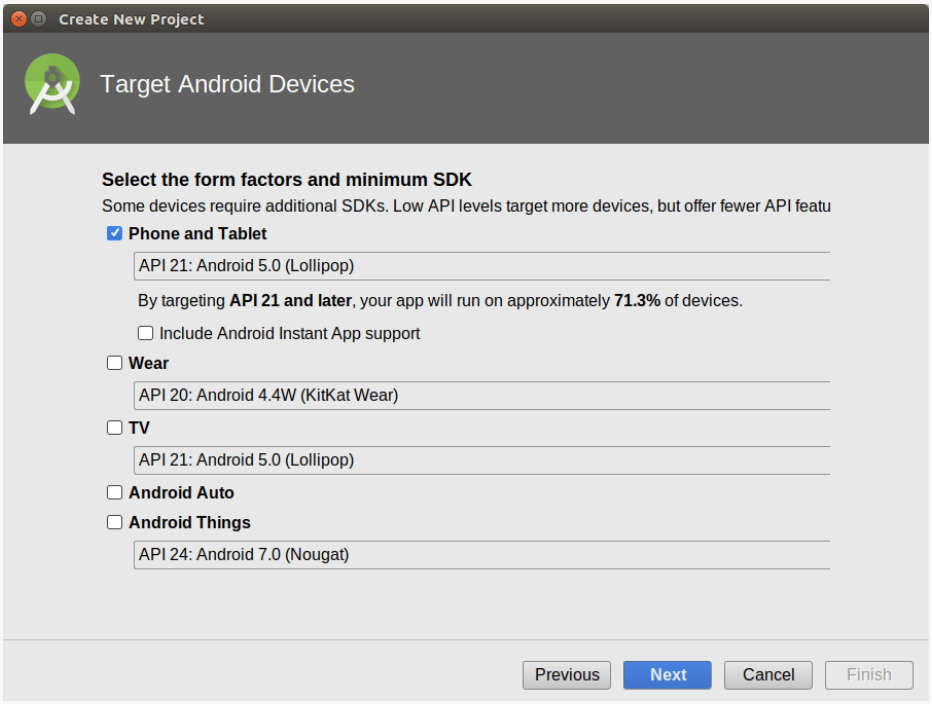

Figure 14: Android Studio Create-Project Wizard, Second Page

The "Minimum SDK" refers to how far back in Android's version history you are willing to support. The lower the value you specify here, the more Android devices can run your app, but the more work you will have to do to test whether your app really does support those devices.

Developers just starting out on Android should only check "Phone and Tablet" as the device type, leaving the other checkboxes unchecked. The default "Minimum SDK" value also usually is a good choice, and it can be changed readily in your project, as we will see later in the book.

Clicking "Next" advances you to the third page of the wizard, where you can choose if Android Studio should create an initial activity for you, and if so, based on what template:

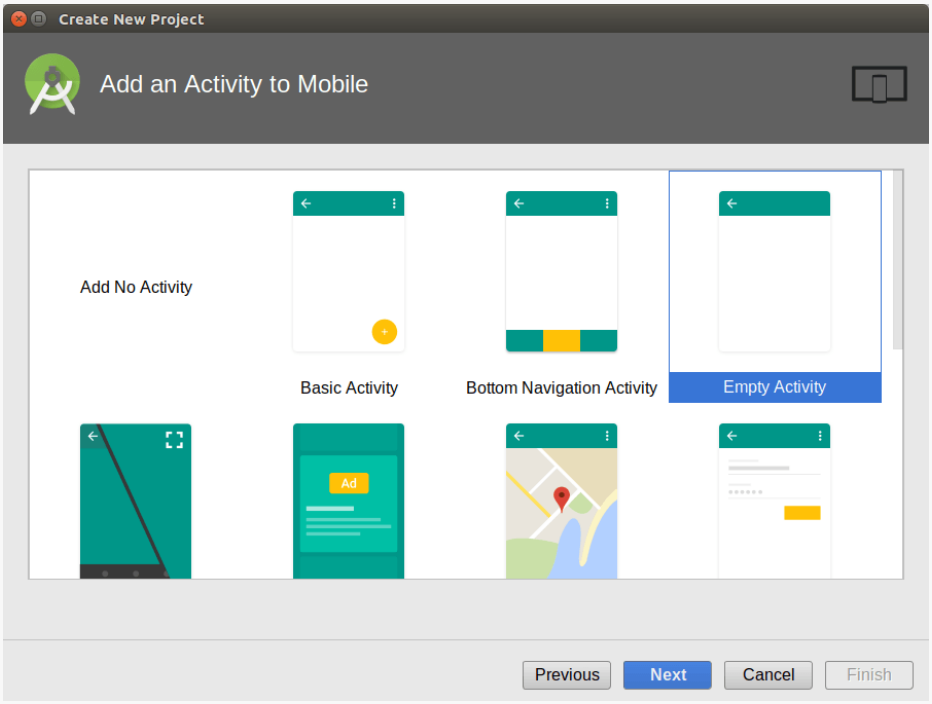

Figure 15: Android Studio Create-Project Wizard, Third Page

None of these templates are especially good, as they add a lot of example material that you will wind up replacing. "Empty Activity" is the best of the available options for first-time Android developers, simply because it adds the least amount of this "cruft".

If you choose any option other than "Add No Activity", clicking "Next" will advance you to a page in the wizard where you can provide additional details about the activity to be created:

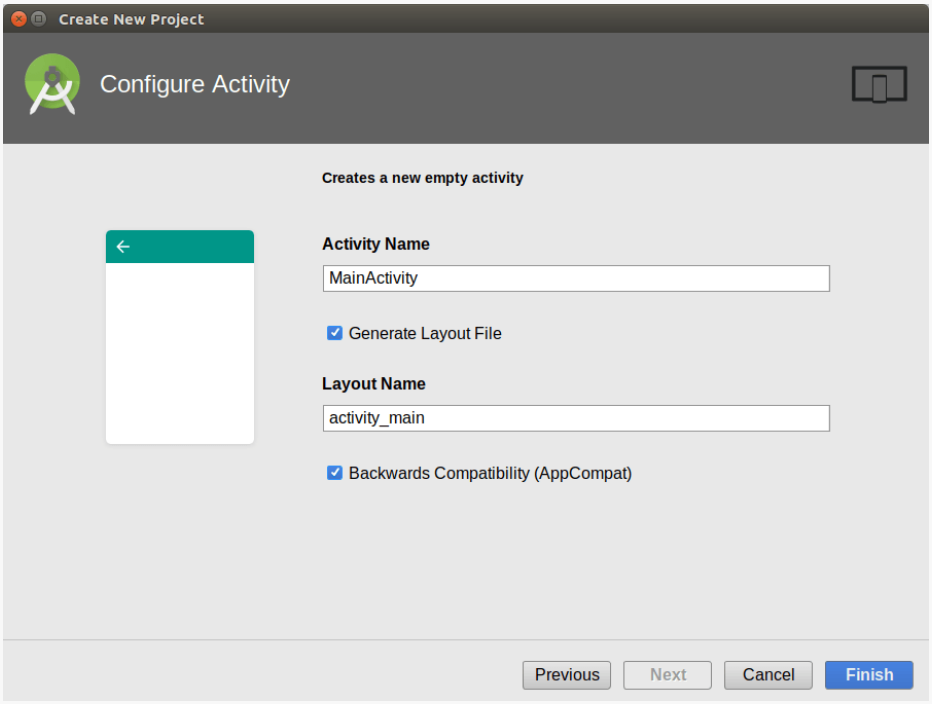

Figure 16: Android Studio Create-Project Wizard, Fourth Page

What options appear here will vary based upon the template you chose in the previous page. Common options include "Activity Name" (the name of the Java class for your activity) and "Layout Name" (the base name of an XML file that will contain a UI definition of your activity).

The "Backwards Compatibility (AppCompat)" checkbox indicates if you want to use a library known as AppCompat. We will discuss using libraries later in the book, as well as what this "AppCompat" is. Unless you know for certain that you want to use AppCompat — and few of this book's example apps do — uncheck this checkbox.

Clicking "Finish" will generate your project files.

Copying a Project

Android Studio projects are simply directories of files, with no special metadata held elsewhere. Hence, to copy a project, just copy its directory.

Importing a Project

You can import a project from one of two places:

- If you are at the initial dialog that you first encountered when you opened Android Studio, choose the "Import Project..." menu item
- If you are inside the Android Studio IDE itself, choose File > New... > Import Project... from the main menu

Then, choose the directory containing the project to be imported.

What happens now depends upon the nature of the project. If the project was already set up for use with Android Studio, or at least with the Android Gradle Plugin, the Android Studio-specific files will be created (or updated) in the project directory.

However, if the project was not set up for Android Studio (or at least for the Android Gradle Plugin), but does have Eclipse project files (or at least a `project.properties` file), you will be led through an Eclipse import wizard. This will be fairly uncommon nowadays.

Starter Project Generators

In addition to creating projects through an IDE's new-project wizard, there are various Web sites that offer online project generators:

- Android Bootstrap
- Android Kickstartr

On those sites, you provide basic configuration data, such as your application's package name, and they generate a complete starter project for you. These projects tend to be significantly more advanced than what you get from the IDE wizards. On the plus side, you get a more elaborate "scaffold" on which you can "hang" your own business logic. However, understanding what those generators create and how to change the generated code requires a fair bit of Android development experience.

Tutorial #2 - Creating a Stub Project

Creating an Android application first involves creating an Android "project". As with many other development environments, the project is where your source code and other assets (e.g., icons) reside. And, the project contains the instructions for your tools for how to convert that source code and other assets into an Android APK file for use with an emulator or device, where the APK is Android's executable file format.

Hence, in this tutorial, we kick off development of a sample Android application, to give you the opportunity to put some of what you are learning in this book in practice.

About Our Tutorial Project

The application we will be building in these tutorials is called `EmPubLite`. `EmPubLite` will be a digital book reader, allowing users to read a digital book like the one that you are reading right now.

`EmPubLite` will be a partial implementation of the `EmPub` reader used for the APK version of this book. `EmPub` itself is a fairly extensive application, so `EmPubLite` will have only a subset of its features.

The "Em" of `EmPub` and `EmPubLite` stands for "embedded". These readers are not designed to read an arbitrary EPUB or MOBI formatted book that you might download from somewhere. Rather, the contents of the book (largely an unpacked EPUB file) will be "baked into" the reader APK itself, so by distributing the APK, you are distributing the book.

About the Rest of the Tutorials

Of course, you may have little interest in writing a digital book reader app.

The tutorials presented in this book are certainly optional. There is no expectation that you have to write any code in order to get value from the book. These tutorials are here simply as a way to help those of you who "learn by doing" have an opportunity to do just that.

Hence, there are any number of ways that you can use these tutorials:

- You can ignore them entirely. That is not the best answer, but you are welcome to do it.
- You can read the tutorials but not actually do any of the work. This is the best low-effort answer, as it is likely that you will learn things from the tutorials that you might have missed by simply reading the non-tutorial chapters.
- You can follow along the steps and actually build the `EmPubLite` app.
- You can download the answers from the book's GitHub repository. There, you will find one directory per tutorial, showing the results of having done the steps in that tutorial. For example, you will find a `T2-Project/` directory containing a copy of the `EmPubLite` sample app after having completed the steps found in this tutorial. You can import these projects into your IDE, examine what they contain, cross-reference them back to the tutorials themselves, and run them.

Any of these are valid options — you will need to choose for yourself what you wish to do.

About Our Tools

The instructions in the remaining tutorials should be accurate for Android Studio 3.0.x. The instructions *may* work for other versions of this IDE, but there may also be some differences.

Step #1: Importing the Project

We need to create the Android project for `EmPubLite`.

Normally, you would use the new-project wizard to create a new project. However, the problem with the new-project wizard is that Google keeps changing what the new-project wizard generates. In most situations, that is not a huge problem. However, it becomes a problem for tutorials like this one, as if Google changes what is in the new project, the tutorial's instructions become out of date.

So, instead, we will import an existing project, so we can start from a stable base.

Visit the releases page of this book's GitHub repository. Then, scroll down to this book's version and download the `EmPubLite-Starter.zip` file for it. UnZIP that project to some place on your development machine. It will unZIP into an `EmPubLite/` directory.

Then, import the project. From the Android Studio welcome dialog, that is handled by the "Import project (Eclipse ADT, Gradle, etc.)" option. From an existing open Android Studio IDE window, you would use File > New > Import Project... from the main menu.

Importing a project brings up a typical directory-picker dialog. Pick the `EmPubLite/` directory and click OK to begin the import process. This may take a while, depending on the speed of your development machine. A "Tip of the Day" dialog may appear, which you can dismiss.

At this point, you should have an empty Android Studio IDE window, probably with an error message:

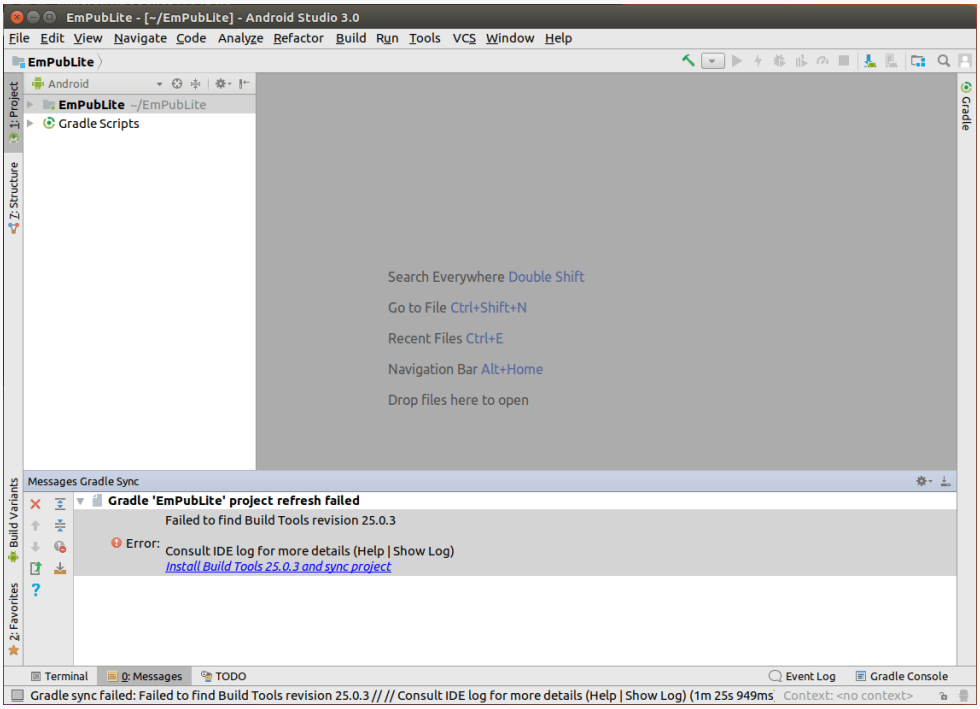

Figure 17: Android Studio, As Initially Launched, Showing Error

In the "Messages Gradle Sync" tool pane, towards the bottom of the screen, you may have a "Failed to find Build Tools revision 25.0.3". Each Android project states what version of the development tools it uses, and this one uses a version slightly older than the current. In that tool pane, the "Install Build Tools 25.0.3 and sync project" message is a hyperlink — click that to download the missing bits. This is a common pattern with these error messages, where the message will contain a link to try to fix the problem.

Next, after several moments, you will get a pop-up dialog like this one:

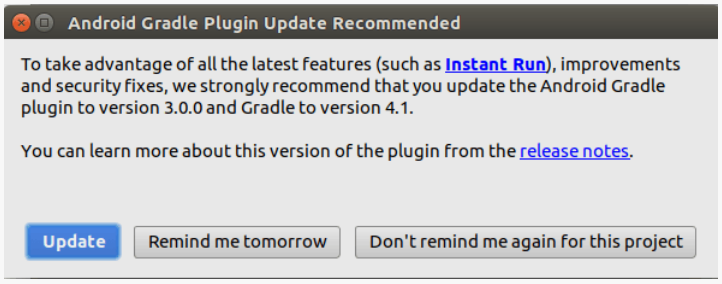

Figure 18: Android Studio, Update Recommendation Dialog

The trigger for this dialog is similar to the trigger for the preceding error message: the project that you imported is looking to use some older tools than what is the latest-and-greatest. For projects that you create yourself from scratch, you will not get this message, as the new-project wizard always uses the latest tools... even if that is not always the best idea. For projects like this one, that you import from elsewhere, this dialog is common. For the purposes of these tutorials, click the "Don't remind me again for this project" button. For other projects that you import, you could opt to click the "Update" button, which will adjust the project to use the newer tools, though this may cause compatibility problems that you would have to debug.

The "Project" tool — docked by default on the left side, towards the top — brings up a way for you to view what is in the project. Android Studio has several ways of viewing the contents of Android projects. The default one, that you are presented with when creating or importing the project, is known as the "Android view":

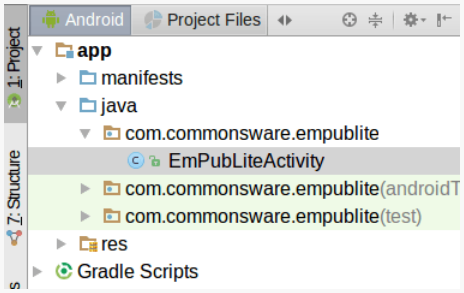

Figure 19: Android Studio "Android View"

While you are welcome to navigate your project using it, the tutorial chapters in this book, where they have screenshots of Android Studio, will show the project view:

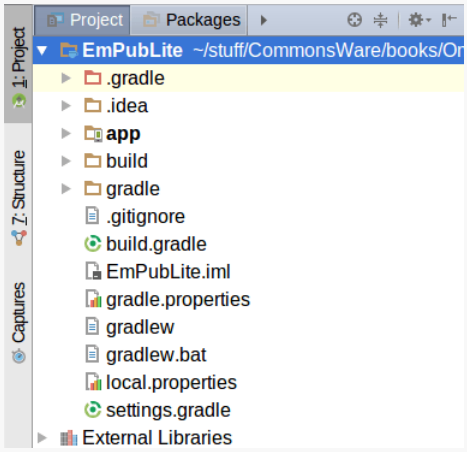

Figure 20: Android Studio "Project View"

To switch to this view — and therefore match what the tutorials will show you — click the "Android" entry above the tree, to display a drop-down of different views. Choose "Project", and that will switch you to the project view used by these tutorials.

Step #2: Get Ready for the x86 Emulator

Your first decision to make is whether or not you want to bother setting up an emulator image right now. If you have an Android device, you may prefer to start testing your app on it, and come back to set up the emulator at a later point. In that case, skip to Step #4.

Otherwise, here is what you may need to do, based on the operating system on your development machine.

Windows

If your CPU met the requirements, and you successfully enabled the right things in your system's BIOS, the Android Studio installation should have installed HAXM, and you should be ready to go.

If, on the other hand, you got some error messages in the installation wizard regarding HAXM, you would need to address those first.

Mac

The wizards of Cupertino set up their Mac hardware to be able to run the Android x86 emulator, which is awfully nice of them, considering that Android competes with iOS. The Android Studio installation wizard should have installed HAXM successfully, and you should be able to continue with the next step of the tutorial.

Linux

The Android x86 emulator on Linux does not use HAXM. Instead, it uses KVM, a common Linux virtualization engine.

If, during the Android Studio installation process, the wizard showed you a page that said that you needed to configure KVM, you will need to do just that before you can set up and use the x86 emulator. The details of how to set up KVM will vary by Linux distro (e.g., Ubuntu).

Step #3: Set Up the AVD

The Android emulator can emulate one or several Android devices. Each configuration you want is stored in an "Android virtual device", or AVD. The AVD Manager is where you create these AVDs.

Note that Android Studio now has its own implementation of the AVD Manager that is separate from the one Android developers have traditionally used. You may see screenshots of the older AVD Manager in blog posts, Stack Overflow answers, and the like. The AVD Manager still fills the same role, but it has a different look and feel.

To open the AVD Manager in Android Studio, choose Tools > Android > AVD Manager from the main menu.

You should be taken to "welcome"-type screen:

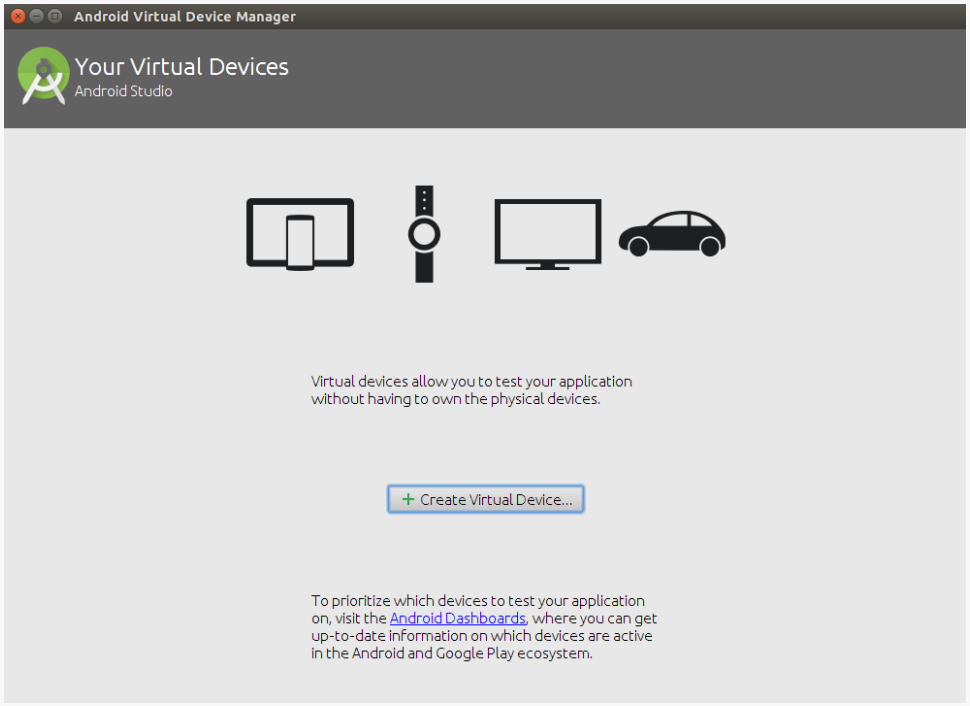

Figure 21: Android Studio AVD Manager, Welcome Screen

Click the "Create Virtual Device" button, which brings up a "Virtual Device Configuration" wizard:

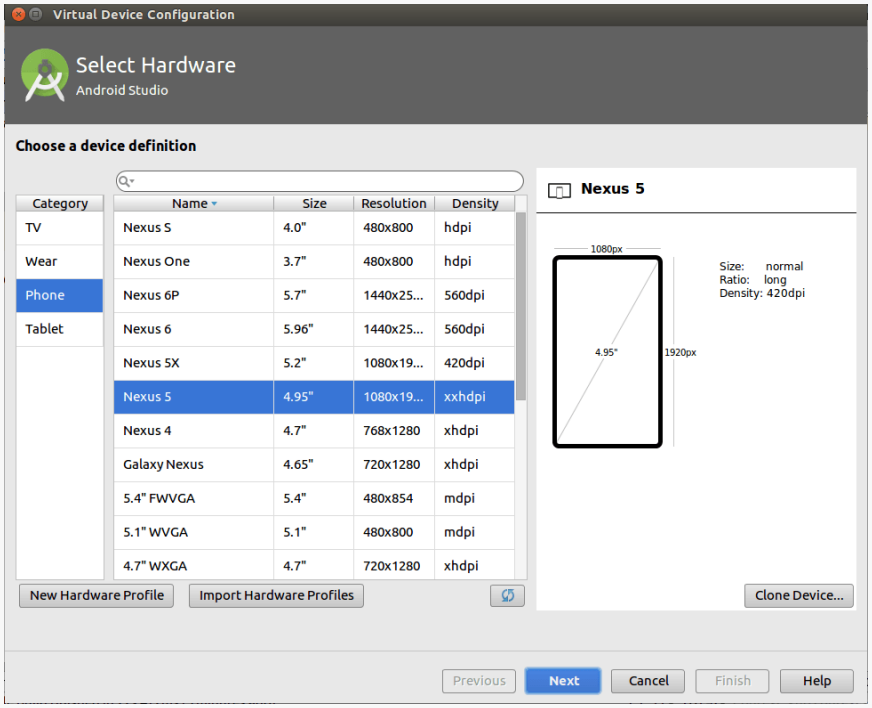

Figure 22: Android Studio Virtual Device Configuration Wizard, First Page

The first page of the wizard allows you to choose a device profile to use as a starting point for your AVD. The "New Hardware Profile" button allows you to define new profiles, if there is no existing profile that meets your needs.

Since emulator speeds are tied somewhat to the resolution of their (virtual) screens, you generally aim for a device profile that is on the low end but is not completely ridiculous. For example, an 800x480 or 1280x768 phone would be considered by many people to be fairly low-resolution. However, there are plenty of devices out there at that resolution (or lower), and it makes for a reasonable starting emulator.

If you want to create a new device profile based on an existing one — to change a few parameters but otherwise use what the original profile had – click the "Clone Device" button once you have selected your starter profile.

However, in general, at the outset, using an existing profile is perfectly fine. The Galaxy Nexus or Nexus 4 images are likely choices to start with.

Clicking "Next" allows you to choose an emulator image to use:

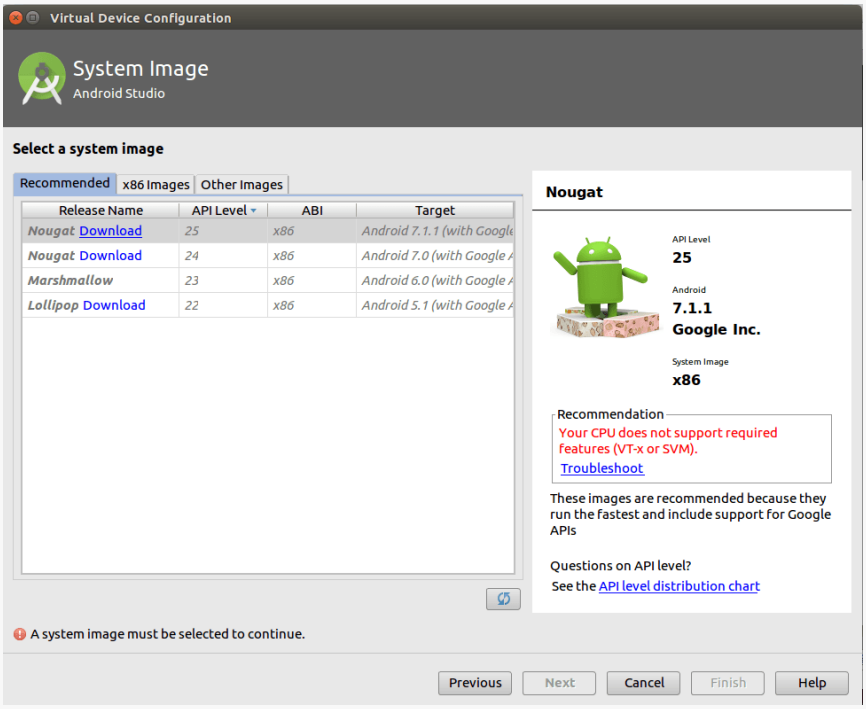

Figure 23: Android Studio Virtual Device Configuration Wizard, Second Page

The emulator images are spread across three tabs:

- "Recommended"
- "x86 Images"
- "Other Images"

For the purposes of the tutorials, you do not need an emulator image with the "Google APIs" — those are for emulators that have Google Play Services in them and related apps like Google Maps. However, in terms of API level, you can choose anything from API Level 15 (Android 4.0.3) on up. You should have one or more suitable images already set up for you, courtesy of having installed Android Studio.

If you click on the x86 Images tab, you should see some images with a "Download" link, and others without it:

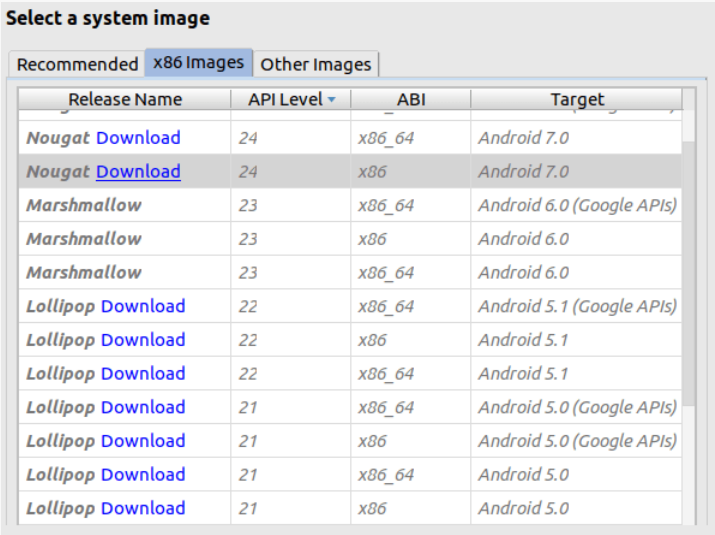

Figure 24: Android Studio Virtual Device Configuration Wizard, x86 Images

The emulator images with "Download" next to them will trigger a one-time download of the files necessary to create AVDs for that particular API level and CPU architecture combination, after another license dialog and progress dialog:

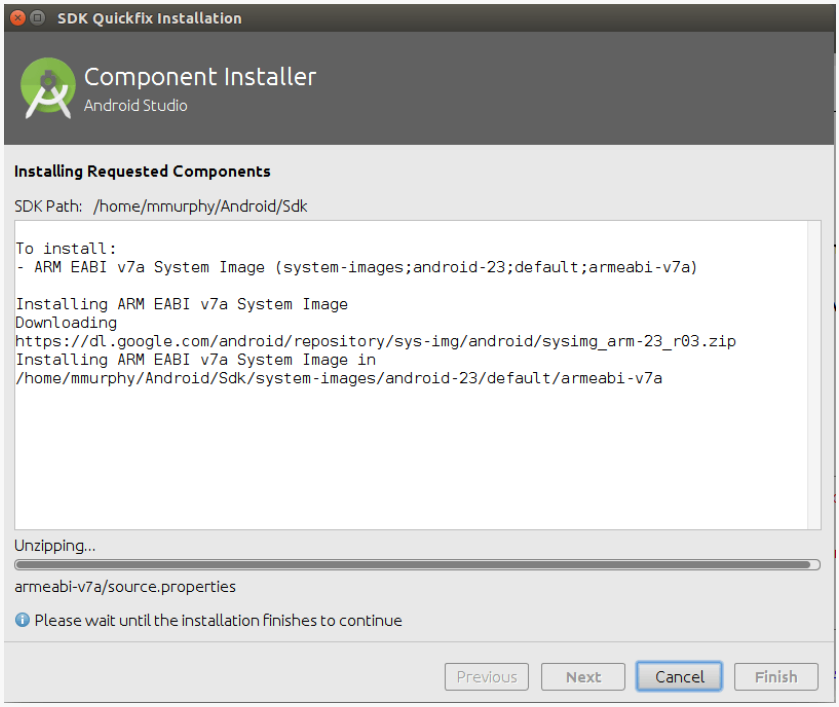

Figure 25: Android Studio Component Installer Dialog, Downloading API 23 ARM Image

Once you have identified the image(s) that you want — and have downloaded any that you did not already have — click on one of them in the wizard:

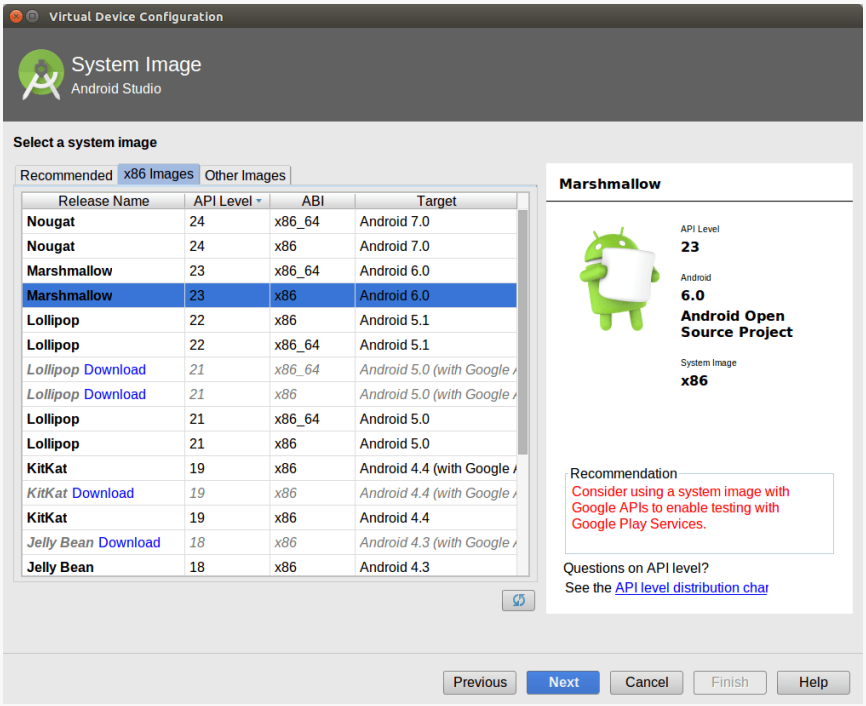

Figure 26: Android Studio Virtual Device Configuration Wizard, After Choosing Image

Clicking "Next" allows you to finalize the configuration of your AVD:

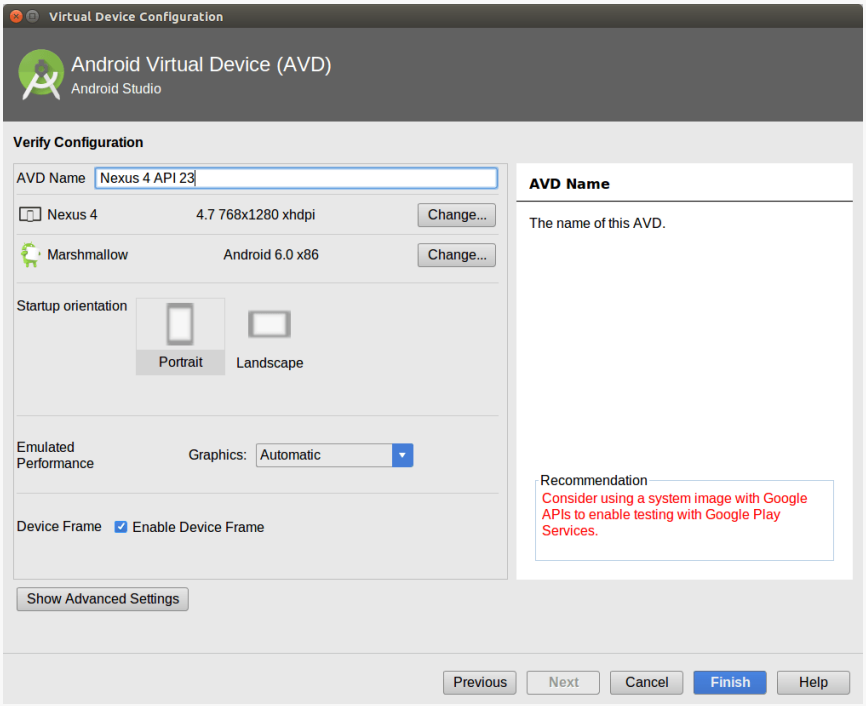

Figure 27: Android Studio Virtual Device Configuration Wizard, Third Page

A default name for the AVD is suggested, though you are welcome to replace this with your own value.

Change the AVD name, if necessary, to something valid: only letters, numbers, spaces, and select punctuation (e.g., `.`, `_`, `-`, `(`, `)`) are supported.

The rest of the default values should be fine for now.

Clicking "Finish" will return you to the main AVD Manager, showing your new AVD. You can then close the AVD Manager window.

Step #4: Set Up the Device

You do not need an Android device to get started in Android application development. Having one is a good idea before you try to ship an application (e.g., upload it to the Play Store). And, perhaps you already have a device – maybe that is what is spurring your interest in developing for Android.

If you do not have an Android device that you wish to set up for development, skip this step.

The first step to make your device ready for use with development is to go into the Settings application on the device. What happens now depends a bit on your Android version:

- On Android 1.x/2.x, go into Applications, then into Development
- On Android 3.0 through 4.1, go into "Developer options" from the main Settings screen
- On Android 4.2 and higher, go into About, tap on the build number seven times, then press BACK, and go into "Developer options" (which was formerly hidden)

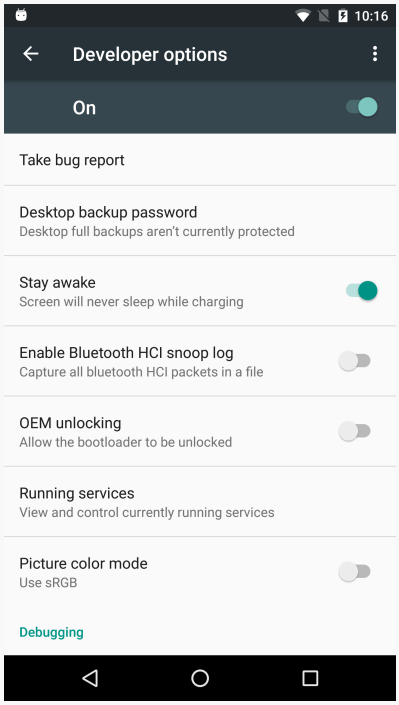

Figure 28: Developer Options, in Settings App

You may need to slide a switch in the upper-right corner of the screen to the "ON" position to modify the values on this screen.

Generally, you will want to scroll down and enable USB debugging, so you can use your device with the Android build tools:

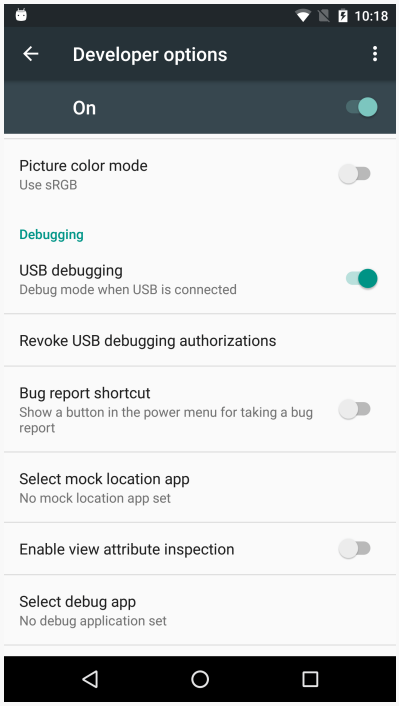

Figure 29: Debugging Options, in Settings App

You can leave the other settings alone for now if you wish, though you may find the "Stay awake" option to be handy, as it saves you from having to unlock your phone all of the time while it is plugged into USB.

Note that on Android 4.2.2 and higher devices, before you can actually use the setting you just toggled, you will be prompted to allow USB debugging with your *specific* development machine via a dialog box:

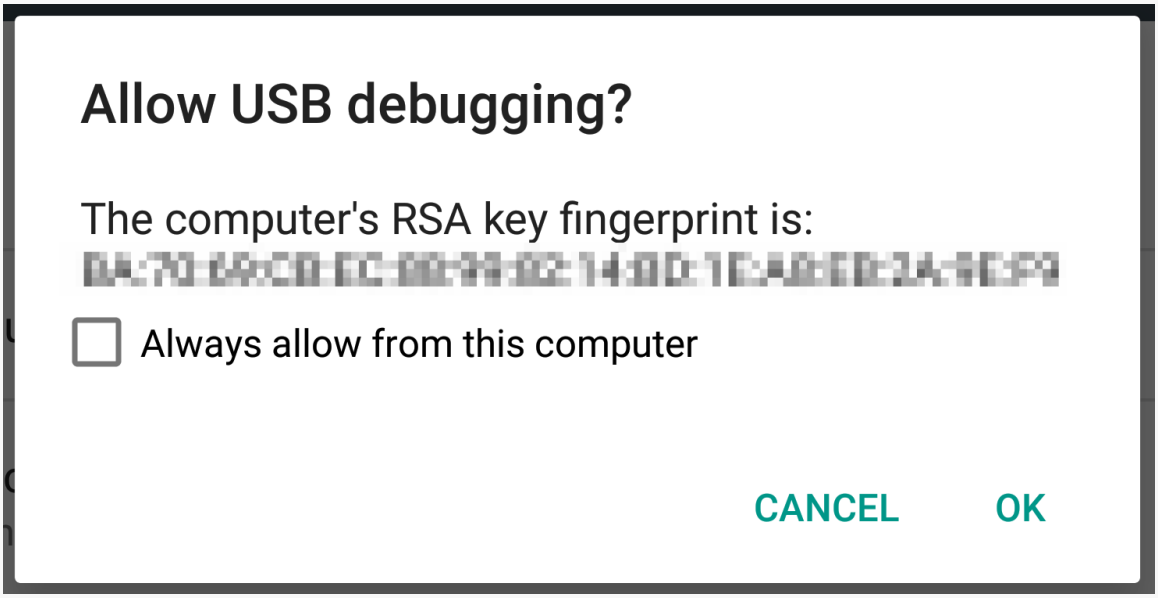

Figure 30: Allow USB Debugging Dialog

This occurs when you plug in the device via the USB cable and have the driver appropriately set up. That process varies by the operating system of your development machine, as is covered in the following sections.

Windows

When you first plug in your Android device, Windows will attempt to find a driver for it. It is possible that, by virtue of other software you have installed, that the driver is ready for use. If it finds a driver, you are probably ready to go.

If the driver is not found, here are some options for getting one.

Windows Update

Some versions of Windows (e.g., Vista) will prompt you to search Windows Update for drivers. This is certainly worth a shot, though not every device will have supplied its driver to Microsoft.

Standard Android Driver

In your Android SDK installation, if you chose to install the "Google USB Driver" package from the SDK Manager, you will find an `extras/google/usb_driver/`

directory, containing a generic Windows driver for Android devices. You can try pointing the driver wizard at this directory to see if it thinks this driver is suitable for your device. This will often work for Nexus devices.

Manufacturer-Supplied Driver

If you still do not have a driver, the OEM USB Drivers in the developer documentation may help you find one for download from your device manufacturer. Note that you may need the model number for your device, instead of the model name used for marketing purposes (e.g., GT-P3113 instead of "Samsung Galaxy Tab 2 7.0").

macOS and Linux

Odds are decent that simply plugging in your device will "just work". You can see if Android recognizes your device via running `adb devices` in a shell (e.g., macOS Terminal), where `adb` is in your `platform-tools/` directory of your SDK. If you get output similar to the following, the build tools detected your device:

```
List of devices attached
HT9CPP809576  device
```

If you are running Ubuntu (or perhaps other Linux variants), and this command did not work, you may need to add some `udev` rules. For example, here is a `51-android.rules` file that will handle the devices from a handful of manufacturers:

```
SUBSYSTEM=="usb", SYSFS{idVendor}=="0bb4", MODE="0666"
SUBSYSTEM=="usb", SYSFS{idVendor}=="22b8", MODE="0666"
SUBSYSTEM=="usb", SYSFS{idVendor}=="18d1", MODE="0666"
SUBSYSTEMS=="usb", ATTRS{idVendor}=="18d1", ATTRS{idProduct}=="0c01", MODE="0666",
OWNER="[me]"
SUBSYSTEM=="usb", SYSFS{idVendor}=="19d2", SYSFS{idProduct}=="1354", MODE="0666"
SUBSYSTEM=="usb", SYSFS{idVendor}=="04e8", SYSFS{idProduct}=="681c", MODE="0666"
```

Drop that in your `/etc/udev/rules.d` directory on Ubuntu, then either reboot the computer or otherwise reload the `udev` rules (e.g., `sudo service udev reload`). Then, unplug and re-plug in the device and see if it is detected.

Step #5: Running the Project

Now, we can confirm that our project is set up properly by running it on a device or emulator.

To do that in Android Studio, just press the Run toolbar button (usually depicted as a green rightward-pointing triangle).

You will then be presented with a dialog indicating where you want the app to run: on some existing device or emulator, or on some newly-launched emulator:

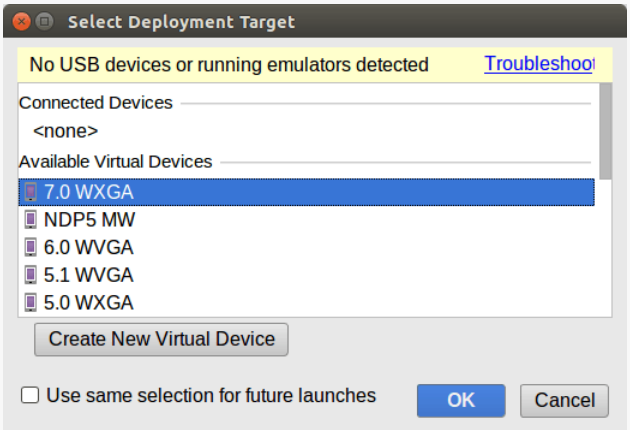

Figure 31: Android Studio Device Chooser Dialog

If you do not have an emulator running, choose one from the list, then click OK. Android Studio will launch your emulator for you.

And, whether you start a new emulator instance or reuse an existing one, your app should appear on it:

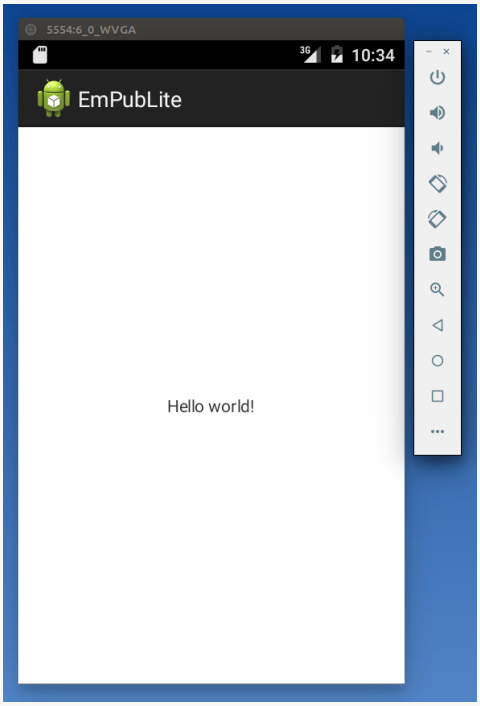

Figure 32: Android 7.0 Emulator with EmPubLite

Note that you may have to unlock your device or emulator to actually see the app running.

The first time you launch the emulator for a particular AVD, you may see this message:

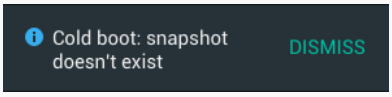

Figure 33: Android Emulator Cold-Boot Warning

The emulator now behaves a bit more like an Android device. Closing the emulator window used to be like completely powering off a phone, but now it is more like tapping the POWER button to turn off the screen. The next time you start that particular AVD, it will wake up to the state in which you left it, rather than booting from scratch ("cold boot"). This speeds up starting the emulator. Occasionally, though, you will have the need to start the emulator as if the device were powering on. To do that, in the AVD Manager, in the drop-down menu in the Actions column, choose "Cold Boot Now".

In Our Next Episode…

... we will modify the `AndroidManifest.xml` file of our tutorial project.

Getting Around Android Studio

This chapter will serve as a quick tour of the Android Studio IDE, to help you get settled in. Other Android-specific capabilities of Android Studio will be explored in the chapters that follow.

Navigating The Project Explorer

After the main editing area — where you will modify your Java source code, your resources, and so forth — the piece of Android Studio you will spend the most time with is the project explorer, usually available on the left side of the IDE window:

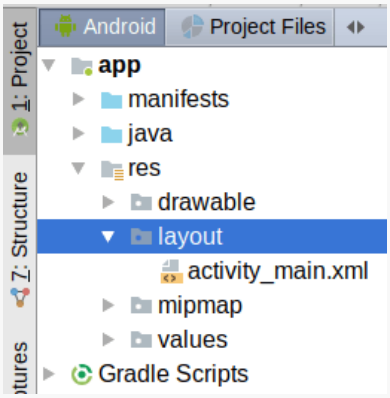

Figure 34: Android Studio Project Explorer, Showing Android Project View

This explorer pane has two main "project views" that an Android developer will use: the Android project view and the classic project view.

Android Project View

By default, when you create or import a project, you will wind up in the Android project view.

In theory, the Android project view is designed to simplify working with Android project files. In practice, it may do so, but only for some advanced developers. On the whole, it makes the IDE significantly more complicated for newcomers to Android, as it is rather difficult to see where things are and what relates to what.

We will return to the Android project view a bit later in the book and explain its benefits relative to resources and Gradle's source sets.

However, for most of the book — most importantly, for the tutorials – we will use the classic project view.

Classic Project View

To switch to the classic project view, click the pair of arrowheads to the right of the "Project Files" tab just above the tree in the explorer, and choose Project:

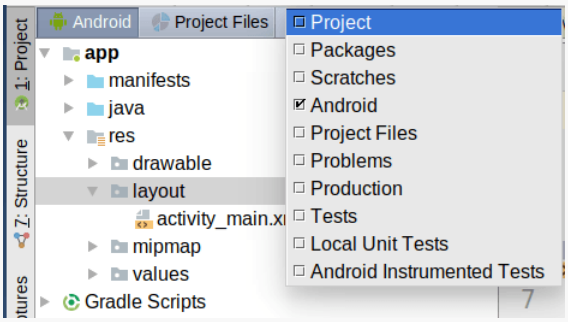

Figure 35: Android Studio Project Explorer, Showing Project View Drop-Down

On some machines, in some cases, the pair of arrowheads is instead a single drop-down arrowhead next to the currently-chosen view (e.g., Android).

Switching to the project view will change the contents of the tree to show you all of the files, in their associated directories:

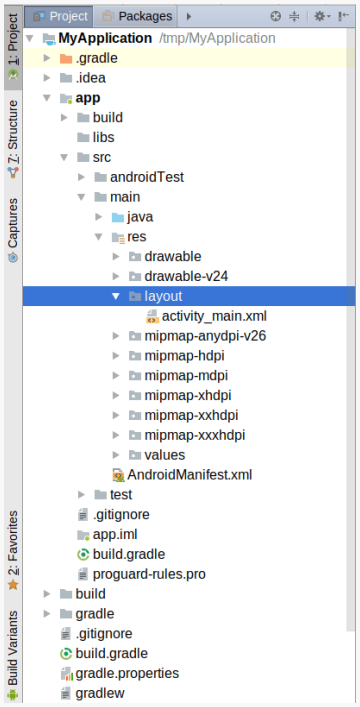

Figure 36: Android Studio Project Explorer, Showing Classic Project View

This project view is much like its equivalent in other IDEs, allowing you to find all of the pieces of your Android project. We will be exploring what those pieces are, and how their files are organized in our projects, in the next chapter.

Context Menus in the Explorer

Right-clicking over a directory or file in the explorer will give you a context menu with a variety of options. Some of these will be typical of any sort of file manager, such as “cut”, “copy”, and/or “paste” options. Some of these will be organized according to how Android Studio manages application development, such as the “Refactor” sub-menu, where you can rename or move files around. Yet others will be specific to Android Studio, such as the ability to invoke wizards to create certain types of Android components or other Java classes.

Opening Files from the Explorer

Double-clicking on a file usually opens that file in a tab that allows you to edit that file, using some sort of editor.

Some file types, like images, can be opened but not edited, as Android Studio does not have editors for all file types.

Running Projects

Of course, as you change your app, you will want to try it out and see if it works, whether on a device or an emulator.

The Basics

As noted in Tutorial #2, to run your project, just press the Run toolbar button:

Figure 37: Android Studio Run Controls, Showing Green Arrow to Run the App

You will then be presented with a dialog indicating where you want the app to run:

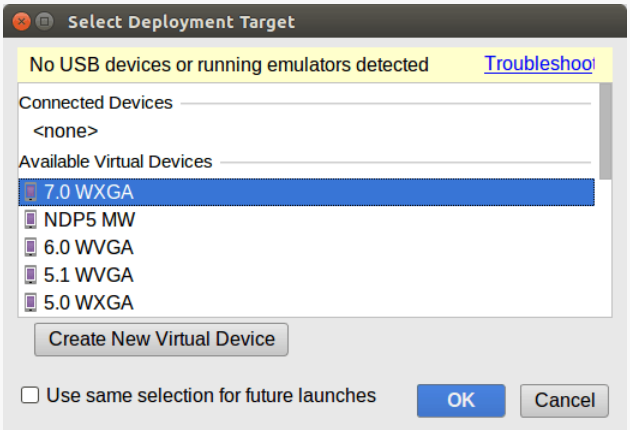

Figure 38: Android Studio Device Chooser Dialog

The "Connected Devices" category lists any devices or running emulators that the build tools can find. Some may be disabled due to compatibility issues, such as having an emulator for an old version of Android where your app requires a newer version of Android.

The "Available Emulators" category lists all AVDs that you have defined in the AVD Manager that are not already running. Again, you may find that some are disabled for compatibility reasons.

The “Create New Emulator” button brings up the wizard to create a new AVD, just like the one you can launch from the AVD Manager.

“Instant Run”

Next to the green “run” arrow button in the toolbar is a lightning bolt button. Sometimes, this will be grayed out and unusable. Other times, it will appear in yellow:

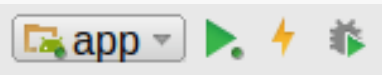

Figure 39: Android Studio Run Controls, With Instant Run Enabled

This button performs what is called “Instant Run”. Instead of building your app and pushing the app to the device or emulator, Instant Run attempts to patch your existing app based on whatever changes you made to the project since you last ran it.

On the plus side, Instant Run is very fast. However, the patched app is not exactly the same as would be your app built from scratch. Feel free to use this for smaller changes if you wish.

Viewing Output

Beyond your app itself, Android Studio will generate other sorts of diagnostic output, in the form of “console”-style transcripts of things that have occurred. The two of these that probably will matter most for you are the Gradle console and Logcat.

Gradle Console

By default, docked in the lower-right corner of your Android Studio window is a “Gradle Console” item. Tapping on that will open up a pane showing the output of attempts to build your application:

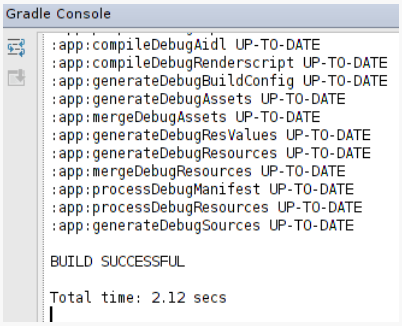

Figure 40: Android Studio Gradle Console

This may automatically appear from time to time, if specific build problems are detected, and you can always go examine it whenever you need.

Click on the "Gradle Console" item again to collapse the view and get it out of your way.

Logcat

Messages that appear at runtime — including the all-important Java stack traces triggered by bugs in your code — are visible in Logcat. The Logcat tool docked towards the lower-left corner of your Android Studio window will display Logcat when tapped:

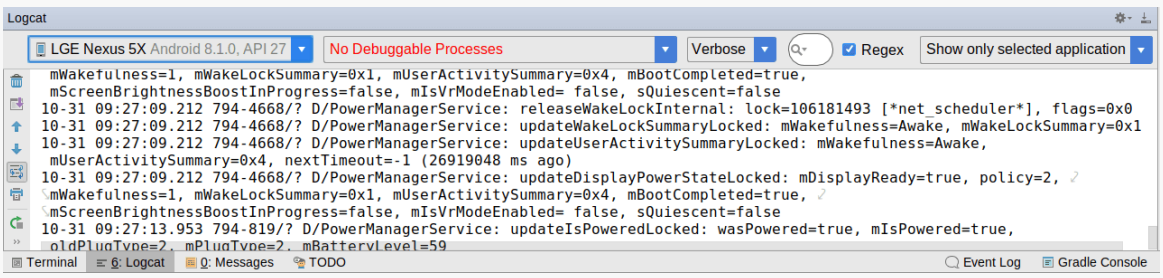

Figure 41: Android Studio Logcat Tool

Logcat is explained in greater detail a bit later in this book.

Accessing Android Tools

Not everything related to Android is directly part of Android Studio itself. In some cases, tools need to be shared between users of Android Studio, users of Eclipse, and

users of "none of the above". In some cases, while the long term direction may be to incorporate the tools' functionality directly into Android Studio, that work simply has not been completed to date.

Here are some noteworthy Android-related tools that you can access via the Tools > Android main menu option.

SDK and AVD Managers

As we saw in Tutorial #1, the SDK Manager is Android's tool for downloading pieces of the Android SDK, including:

- "SDK Platform" editions, allowing us to compile against a particular API level
- ARM and (sometimes) x86 emulator images
- Documentation
- Updates to the core build tools
- Etc.

You can launch the SDK Manager via Tools > Android > SDK Manager from the Android Studio main menu, or by clicking on the "droid in a box" toolbar button:

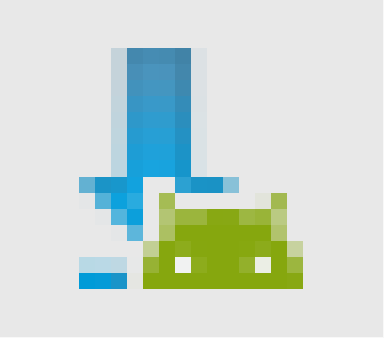

Figure 42: Android Studio SDK Manager Toolbar Icon

The AVD Manager is the tool for creating emulators that emulate certain Android environments, based upon API level, screen size, and other characteristics.

You can launch the AVD Manager via Tools > Android > AVD Manager from the Android Studio main menu, or by clicking the "droid and a screen" toolbar button:

Figure 43: Android Studio AVD Manager Toolbar Icon

Android Studio and Release Channels

When you install Android Studio for the first time, your installation will be set up to get updates on the "stable" release channel. Here, a "release channel" is a specific set of possible upgrades. The "stable" release channel means that you are getting full production-ready updates. Android Studio will check for updates when launched, and you can manually check for updates via the main menu (e.g., Help > Check for Update... on Windows and Linux).

If an update is available, you will be presented with a dialog box showing you details of the update:

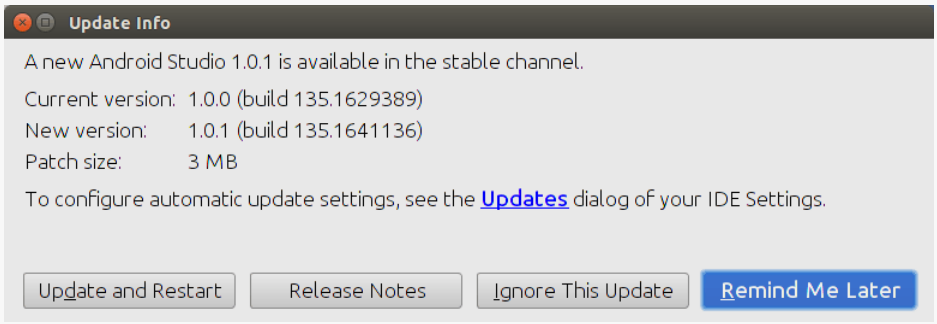

Figure 44: Android Studio Update Dialog

Choosing "Release Notes" will bring up a Web page with release notes for the new release. Clicking "Update and Restart" does pretty much what the button name suggests: it downloads the update and restarts the IDE, applying the update along the way.

Clicking the "Updates" hyperlink in the dialog brings up yet another dialog, allowing you to choose which release channel you want to subscribe to:

Figure 45: Android Studio Update Release Channel Dialog

You have four channels to choose from:

- Stable, which is appropriate for most developers
- Beta, which will get updates that are slightly ahead of stable
- Dev, which is even more ahead than is the beta channel
- Canary, which is updated *very* early (and the name, suggestive of a "canary in a coal mine", indicates that you are here to help debug the IDE)

Visit the Trails!

Android Studio's Project Structure dialog and Translations Editor are covered later in this book.

Contents of Android Projects

The Android build system is organized around a specific directory tree structure for your Android project, much like any other Java project. The specifics, though, are fairly unique to Android — the Android build tools do a few extra things to prepare the actual application that will run on the device or emulator.

Here is a quick primer on the project structure, to help you make sense of it all, particularly for the sample code referenced in this book.

What You Get, In General

The details of *exactly* what files are in your project depend on a variety of things:

- What IDE and version the project was used to create the project
- What project template was used to create the project
- What other changes have been made to the project after it was created

However, usually, there are many elements in common.

The Modules

A default Android Studio project will have an `app/` directory off of the project root directory (i.e., the directory in which you told Android Studio to create the project). That `app/` directory represents what Android Studio refers to as a module. Most projects just have this one `app/` module, though you can have more than one module if needed.

The Source Sets

Inside of `app/` you will find a `src/main/` directory. This represents the `main` source set, and it contains all of the "source" that your project is contributing to build the application. Here, "source" means more than just programming language source code (e.g., Java). It also includes other types of files, such as resources and the manifest, that contribute to the app.

The Manifest

Inside of `app/src/main/`, you will find a file named `AndroidManifest.xml`. `AndroidManifest.xml` is an XML file describing the application being built and what components — activities, services, etc. — are being supplied by that application. You can think of it as being the "table of contents" of what your application is about, much as a book has a "table of contents" listing the various parts, chapters, and appendices that appear in the book.

We will examine the manifest a bit more closely starting in the next chapter.

The Java

When you created the project, if you had Android Studio create an activity for you, you supplied the class name of the "main" activity for the application (e.g., `MainActivity`). That will be combined with the package name that you provided for the project to determine the fully-qualified class name for this activity (e.g., `com.commonsware.android.MainActivity`).

You will find that your project's Java source tree already has the package's directory tree in place, plus a class representing your requested activity (e.g., `com/commonsware/android/MainActivity.java`). This will be inside the `main` source set, so the full path from the project root would be something like `app/src/main/java/com/commonsware/android/MainActivity.java`.

You are welcome to modify this file and add Java classes as needed to implement your application, and we will demonstrate that countless times as we progress through this book.

Elsewhere — in directories that you normally do not work with — the Android build tools will also be code-generating some source code for you each time you build your app. One of the code-generated Java classes (`R.java`) will be important for

controlling our user interfaces from our own Java code, and we will see many references to this `R` class as we start building applications in earnest.

The Resources

You will also find that your project has a `res/` directory tree inside of the `main` source set. This holds "resources" — static files that are packaged along with your application, either in their original form or, occasionally, in a preprocessed form. Some of the subdirectories you will find or create under `res/` include:

1. `res/drawable/` and `res/mipmap-*/` (for a few values of `*`) for images (PNG, JPEG, etc.)
2. `res/layout/` for XML-based UI layout specifications
3. `res/menu/` for XML-based menu specifications
4. `res/raw/` for general-purpose files (e.g., an audio clip, a CSV file of account information)
5. `res/values/` for strings, dimensions, and the like
6. `res/xml/` for other general-purpose XML files you wish to ship

Some of the directory names may have suffixes, like `res/mipmap-hdpi/`. This indicates that the directory of resources should only be used in certain circumstances — in this case, the mipmap resources are designed for devices with high-density screens.

We will cover all of these, and more, later in this book.

The Build Instructions

The IDE needs to know how to take all of this stuff and come up with an Android APK file. Some of this is already "known" to the IDE based upon how the IDE was written. But some details are things that you may need to configure from time to time, and so those details are stored in files that you will edit, by one means or another, from your IDE.

In Android Studio, most of this knowledge is kept in files named `build.gradle`. These are for a build engine known as Gradle, that Android Studio uses to build APKs and other Android outputs.

More About the Directory Structure

All of those items are stored in a particular directory structure in an Android Studio project... at least by default. Android Studio and Gradle are powerful and can be configured to handle other structures, though most projects stick with the standard setup.

The Root Directory

In the root directory of your project, the most important item is the `app/` directory representing your application module. We will look at that more in the next section.

Beyond the `app/` directory, the other noteworthy files in the root of your project include:

- `build.gradle`, which is part of the build instructions for your project, as is described above
- Various other Gradle-related files (`settings.gradle`, `gradle.properties`, `gradlew`, `gradlew.bat`, and so forth)
- `local.properties`, which indicates where your Android SDK tools reside
- An `.iml` file, where Android Studio holds some additional metadata about your project
- A `.gitignore` file, representing standard rules for what should and should not go into version control, particularly with respect to the Git version control system

Eventually, you will have:

- A `build/` directory, containing the compiled output of your app, plus various reports and other files related to the build process and app testing
- A `.gradle/` directory, containing Gradle executable code
- An `.idea/` directory — this, along with the `.iml` file, represents data needed by IntelliJ IDEA, on which Android Studio is based

The App Directory

The `app/` directory, and its contents, are where you will spend most of your time as a developer. Only infrequently do you need to manipulate the files in the project root.

The most important thing in the `app/` directory is the `src/` directory, which is the root of your project's source sets. We will explore those more in the next section.

Beyond the `src/` directory, there are a few other items of note in `app/`:

- A `build/` directory, which will hold the outputs of building your app, including your APK file
- A `build.gradle` file, where most of your project-specific Gradle configuration will go, to teach Android Studio how to build your app
- An `app.iml` file, containing more Android Studio metadata
- Another `.gitignore` file, for overrides to the Git version control rules from the `.gitignore` file in the project root
- `proguard-rules.pro`, which are rules for a tool called ProGuard, which helps reduce the size of your app

The Source Sets

Source sets are where the "source" of your project is organized. As noted earlier, "source" not only refers to programming language source code (e.g., Java), but other types of inputs to the build, such as your resources.

The source set that you will spend most of your time in is `main/`. You may also have stub source sets named `androidTest` and `test`, for use in testing your app, as will be covered later in the book.

Inside of a source set, common items include:

- Java code, in a `java/` directory
- Resources, in a `res/` directory
- Assets, in an `assets/` directory, representing other static files you wish packaged with the application for deployment onto the device
- Your `AndroidManifest.xml` file

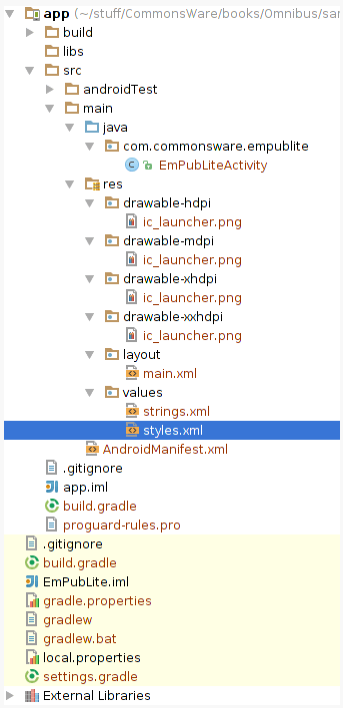

Figure 46: Android Studio Project Explorer, Showing EmPubLite

Some projects will have additional items, usually tied to specific add-on tools that the project happens to employ.

What You Get Out Of It

As part of running your app on a device or emulator, the IDE will generate an APK file. You will find this in the `build/outputs/apk` directory of your module's directory, (e.g., `app/build/outputs/apk` for a traditional Android Studio project).

The APK file is a ZIP archive containing your compiled Java classes along with packaged versions of the rest of your source (e.g., resources, manifest). The APK is what gets distributed to your users, whether through an app distribution service like Google's Play Store or through other means.

Introducing Gradle and the Manifest

In the discussion of Android Studio, this book has mentioned something called "Gradle", without a lot of explanation.

In this chapter, the mysteries of Gradle will be revealed to you.

(well, OK, *some* of the mysteries...)

We also mentioned in passing in the previous chapter the concept of the "manifest" — `AndroidManifest.xml` — as being a special file in our Android projects.

On the one hand, Gradle and the manifest are not strictly related. On the other hand, some (but far from all) of the things that we can set up in the manifest can be overridden in Gradle.

So, in this chapter, we will review both what Gradle is, what the manifest is, what each of their roles are, and the basics of how they tie together.

Gradle: The Big Questions

First, let us "set the stage" by examining what this is all about, through a series of fictionally-asked questions (FAQs).

What is Gradle?

Gradle is software for building software, otherwise known as "build automation software" or "build systems". You may have used other build systems before in other environments, such as `make` (C/C++), `rake` (Ruby), Ant (Java), Maven (Java), etc.

These tools know — via intrinsic capabilities and rules that you teach them — how to determine what needs to be created (e.g., based on file changes) and how to create them. A build system does not compile, link, package, etc. applications directly, but instead directs separate compilers, linkers, and packagers to do that work.

Gradle uses a domain-specific language (DSL) built on top of Groovy to accomplish these tasks.

What is Groovy?

There are many programming languages that are designed to run on top of the Java VM. Some of these, like JRuby and Jython, are implementations of other common programming languages (Ruby and Python, respectively). Other languages are unique, and Groovy is one of those.

Groovy scripts look a bit like a mashup of Java and Ruby. As with Java, Groovy supports:

- Defining classes with the `class` keyword
- Creating subclasses using `extends`
- Importing classes from external JARs using `import`
- Defining method bodies using braces (`{` and `}`)
- Objects are created via the `new` operator

As with Ruby, though:

- Statements can be part of a class, or simply written in an imperative style, like a scripting language
- Parameters and local variables are not typed
- Values can be automatically patched into strings, though using slightly different syntax (`"Hello, $name"` for Groovy instead of `"Hello, #{name}"` for Ruby)

Groovy is an interpreted language, like Ruby and unlike Java. Groovy scripts are run by executing a **`groovy`** command, passing it the script to run. The Groovy runtime, though, is a Java JAR and requires a JVM in order to operate.

One of Groovy's strengths is in creating a domain-specific language (or DSL). Gradle, for example, is a Groovy DSL for doing software builds. Gradle-specific capabilities appear to be first-class language constructs, generally indistinguishable

from capabilities intrinsic to Groovy. Yet, the Groovy DSL is largely declarative, like an XML file.

To some extent, we get the best of both worlds: XML-style definitions (generally with less punctuation), yet with the ability to "reach into Groovy" and do custom scripting as needed.

What Does Android Have To Do with Gradle?

Google has published the Android Gradle Plugin, which gives Gradle the ability to build Android projects. Google is also using Gradle and the Android Gradle Plugin as the build system behind Android Studio.

Obtaining Gradle

As with any build system, to use it, you need the build system's engine itself.

If you will only be using Gradle in the context of Android Studio, the IDE will take care of getting Gradle for you. If, however, you are planning on using Gradle outside of Android Studio (e.g., command-line builds), you will want to consider where your Gradle is coming from. This is particularly important for situations where you want to build the app with no IDE in sight, such as using a continuous integration (CI) server, like Jenkins.

Also, the way that Android Studio works with Gradle — called the Gradle Wrapper – opens up security issues for your development machine, if you are the sort to download open source projects from places like GitHub and try using them.

Direct Installation

What most developers looking to use Gradle outside of Android Studio will wind up doing is installing Gradle directly.

The Gradle download page contains links to ZIP archives for Gradle itself: binaries, source code, or both.

You can unZIP this archive to your desired location on your development machine.

Linux Packages

You may be able to obtain Gradle via a package manager on Linux environments. For example, there is an Ubuntu PPA for Gradle.

The gradlew Wrapper

If you are starting from a project that somebody else has published, you may find a `gradlew` and `gradlew.bat` file in the project root, along with a `gradle/` directory. This represents the "Gradle Wrapper".

The Gradle Wrapper consists of three pieces:

- the batch file (`gradlew.bat`) or shell script (`gradlew`)
- the JAR file used by the batch file and shell script (in the `gradle/wrapper/` directory)
- the `gradle-wrapper.properties` file (also in the `gradle/wrapper/` directory)

Android Studio uses the `gradle-wrapper.properties` file to determine where to download Gradle from, for use in your project, from the `distributionUrl` property in that file:

```
#Sun Nov 05 06:56:08 EST 2017
distributionBase=GRADLE_USER_HOME
distributionPath=wrapper/dists
zipStoreBase=GRADLE_USER_HOME
zipStorePath=wrapper/dists
distributionUrl=https\://services.gradle.org/distributions/gradle-4.1-all.zip
```

(from Basic/Button/gradle/wrapper/gradle-wrapper.properties)

When you create or import a project, or if you change the version of Gradle referenced in the properties file, Android Studio will download the Gradle pointed to by the `distributionUrl` property and install it to a `.gradle/` directory (note the leading `.`) in your project. That version of Gradle will be what Android Studio uses.

RULE #1: Only use a `distributionUrl` that you trust.

If you are importing an Android project from a third party — such as the samples for this book — and they contain the `gradle/wrapper/gradle-wrapper.properties` file, examine it to see where the `distributionUrl` is pointing to. If it is loading from `services.gradle.org`, or from an internal enterprise server, it is probably

trustworthy. If it is pointing to a URL located somewhere else, consider whether you really want to use that version of Gradle, considering that it may have been tampered with.

The batch file, shell script, and JAR file are there to support command-line builds. If you run the `gradlew` command, it will use a local copy of Gradle installed in `.gradle/` in the project. If there is no such copy of Gradle, `gradlew` will download Gradle from the `distributionUrl`, as does Android Studio. Note that Android Studio does not use `gradlew` for this role — that logic is built into Android Studio itself.

RULE #2: Only use a `gradlew` that you REALLY trust.

It is relatively easy to examine a `.properties` file to check a URL to see if it seems valid. Making sense of a batch file or shell script can be cumbersome. Decompiling a JAR file and making sense of it can be rather difficult. Yet, if you use `gradlew` that you obtained from somebody, that script and JAR are running on your development machine, as is the copy of Gradle that they install. If that code was tampered with, the malware has complete access to your development machine and anything that it can reach, such as servers within your organization.

Note that you do not have to use the Gradle Wrapper at all. If you would rather not worry about it, install a version of Gradle on your development machine yourself and remove the Gradle Wrapper files. You can use the `gradle` command to build your app (if your Gradle's `bin/` directory is in your `PATH`), and Android Studio will use your Gradle installation (if you teach it where to find it, such as via the `GRADLE_HOME` environment variable).

Versions of Gradle and the Android Gradle Plugin

The Android Gradle Plugin that we will use to give Gradle "super Android powers!" is updated periodically. Each update has its corresponding required version of Gradle. Google maintains a page listing the Gradle versions supported by each Android Gradle Plugin version

If you are using the Gradle Wrapper, you are using an installation of Gradle that is local to the project. So long as the version of Gradle in the project matches the version of the Android Gradle Plugin requested in the project's `build.gradle` file — as will be covered later in this chapter — you should be in fine shape.

If you are not using the Gradle Wrapper, you will need to decide when to take on a new Android Gradle Plugin release and plan to update your Gradle installation and `build.gradle` files in tandem at that point.

Gradle Environment Variables

If you installed Gradle yourself, you will want to define a `GRADLE_HOME` environment variable, pointing to where you installed Gradle, and to add the `bin/` directory inside of Gradle to your `PATH` environment variable.

You may also consider setting up a `GRADLE_USER_HOME` environment variable, pointing to a directory in which Gradle can create a `.gradle/` subdirectory, for per-user caches and related materials. By default, Gradle will use your standard home directory.

Examining the Gradle Files

An Android Studio project usually has two `build.gradle` files, one at the project level and one at the "module" level (e.g., in the `app/` directory).

The Project-Level File

The `build.gradle` file in the project directory controls the Gradle configuration for all modules in your project. Right now, most likely you only have one module, and many apps only ever use one module. However, it is possible for you to add other modules to this project, and we will explore reasons for doing so later in this book.

Here is a typical top-level `build.gradle` file:

```
// Top-level build file where you can add configuration options common to all
sub-projects/modules.

buildscript {

    repositories {
        google()
        jcenter()
    }
    dependencies {
        classpath 'com.android.tools.build:gradle:3.0.0'
```

```
        // NOTE: Do not place your application dependencies here; they belong
        // in the individual module build.gradle files
    }
}

allprojects {
    repositories {
        google()
        jcenter()
    }
}

task clean(type: Delete) {
    delete rootProject.buildDir
}
```

buildscript

In Groovy terms, a "closure" is a block of code wrapped in braces (`{ }`).

The `buildscript` closure in Gradle is where you configure the JARs and such that Gradle itself will use for interpreting the rest of the file. Hence, here you are not configuring your *project* so much as you are configuring *the build itself*.

The `repositories` closure inside the `buildscript` closure indicates where plugins can come from. Here, `jcenter()` is a built-in method that teaches Gradle about JCenter, a popular location for obtaining open source libraries. Similarly, `google()` is a built-in method that teaches Gradle about a site where it can download plugins from Google.

The `dependencies` closure indicates what is required to be able to run the rest of the build script. `classpath 'com.android.tools.build:gradle:3.0.0'` is not especially well-documented by the Gradle team. However the `'com.android.tools.build:gradle:3.0.0'` portion means:

- Find the `com.android.tools.build` group of plugins
- Find the `gradle` artifact within that group
- Ensure that we have version `3.0.0` of the plugin

The first time you run your build, with the `buildscript` closure as shown above, Gradle will notice that you do not have this dependency. It will then download that artifact from Google, as Google serves up its plugin from its own site nowadays.

Sometimes, the last segment of the version is replaced with a `+` sign (e.g., `3.0.+`). This tells Gradle to download the latest version, thereby automatically upgrading you to the latest patch-level (e.g., `3.0.1` at some point).

allprojects

The `allprojects` closure says "apply these settings to all modules in this project". Here, we are setting up `jcenter()` and `google()` as places to find libraries used in any of the modules in our project. We will use lots of libraries in our projects — having these "repositories" set up in `allprojects` makes it simpler for us to request them.

The Module-Level Gradle File

In your `app/` module, you will also find a `build.gradle` file. This has settings unique for this module, independent of any other module that your project may have in the future.

Here is a typical module-level `build.gradle` file:

```
apply plugin: 'com.android.application'

android {
    compileSdkVersion 26
    defaultConfig {
        applicationId "com.commonsware.myapplication"
        minSdkVersion 21
        targetSdkVersion 26
        versionCode 1
        versionName "1.0"
        testInstrumentationRunner "android.support.test.runner.AndroidJUnitRunner"
    }
    buildTypes {
        release {
            minifyEnabled false
            proguardFiles getDefaultProguardFile('proguard-android.txt'),
'proguard-rules.pro'
        }
    }
}

dependencies {
    implementation fileTree(dir: 'libs', include: ['*.jar'])
    implementation 'com.android.support.constraint:constraint-layout:1.0.2'
```

```
    testImplementation 'junit:junit:4.12'
    androidTestImplementation 'com.android.support.test:runner:1.0.1'
    androidTestImplementation 'com.android.support.test.espresso:espresso-core:3.0.1'
}
```

For now, let's focus on some key elements of this file.

dependencies

This `build.gradle` file also has a `dependencies` closure. Whereas the `dependencies` closure in the `buildscript` closure in the top-level `build.gradle` file is for libraries used by the build process, the `dependencies` closure in the module's `build.gradle` file is for libraries used by your code in that module. We will get into the concept of these libraries later in the book.

android

The `android` closure contains all of the Android-specific configuration information. This closure is what the Android plugin enables, where the plugin itself comes from the `apply plugin: 'com.android.application'` line at the top, coupled with the `classpath` line from the project-level `build.gradle` file.

But before we get into what is in this closure, we should "switch gears" and talk about the manifest file, as what goes in the `android` closure is related to what goes in the manifest file.

Introducing the Manifest

The foundation for any Android application is the manifest file: `AndroidManifest.xml`. This will be in your `app` module's `src/main/` directory (the `main` source set) for typical Android Studio projects.

Here is where you declare what is inside your application — the activities, the services, and so on. You also indicate how these pieces attach themselves to the overall Android system; for example, you indicate which activity (or activities) should appear on the device's main menu (a.k.a., launcher).

When you create your application, you will get a starter manifest generated for you. For a simple application, offering a single activity and nothing else, the auto-generated manifest will probably work out fine, or perhaps require a few minor

modifications. On the other end of the spectrum, the manifest file for the Android API demo suite is over 1,000 lines long. Your production Android applications will probably fall somewhere in the middle.

As mentioned previously, some items can be defined in both the manifest and in a `build.gradle` file. The approach of putting that stuff in the manifest still works. For Android Studio users, you will probably use the Gradle file and not have those common elements be defined in the manifest.

Things In Common Between the Manifest and Gradle

There are a few key items that can be defined in the manifest and can be overridden in `build.gradle` statements. These items are fairly important to the development and operation of our Android apps as well.

Package Name and Application ID

The root of all manifest files is, not surprisingly, a `manifest` element:

```
<manifest xmlns:android="http://schemas.android.com/apk/res/android"
  package="com.commonsware.empublite">
```

Note the `android` namespace declaration. You will only use the namespace on many of the attributes, not the elements (e.g., `<manifest>`, not `<android:manifest>`).

The biggest piece of information you need to supply on the `<manifest>` element is the `package` attribute.

The `package` attribute will always need to be in the manifest, even for Android Studio projects. The `package` attribute will control where some source code is generated for us, notably some `R` and `BuildConfig` classes that we will encounter later in the book.

Since the `package` value is used for Java code generation, it has to be a valid Java package name. Java convention says that the package name should be based on a reverse domain name (e.g., `com.commonsware.myapplication`), where you own the domain in question. That way, it is unlikely that anyone else will accidentally collide with the same name.

The `package` also serves as our app's default "application ID". This needs to be a unique identifier, such that:

- no two apps can be installed on the same device at the same time with the same application ID
- no two apps can be uploaded to the Play Store with the same application ID (and other distribution channels may have the same limitation)

By default, the application ID is the `package` value, but Android Studio users can override it in their Gradle build files. Specifically, inside of the `android` closure can be a `defaultConfig` closure, and inside of there can be an `applicationId` statement:

```
android {
    // other stuff

    defaultConfig {
        applicationId "com.commonsware.myapplication"
        // more other stuff
    }
}
```

Not only can Android Studio users override the application ID in the `defaultConfig` closure, but there are ways of having different application ID values for different scenarios, such as a debug build versus a release build. We will explore that more later in the book.

minSdkVersion and targetSdkVersion

Your `defaultConfig` closure inside the `android` closure in your module's `build.gradle` file has a pair of properties named `minSdkVersion` and `targetSdkVersion`. Technically, these override values that could be defined via a `<uses-sdk>` element in the manifest, though few projects will have such an element nowadays.

Of the two, the more critical one is `minSdkVersion`. This indicates what is the oldest version of Android you are testing with your application. The value of the attribute is an integer representing the Android API level. So, if you are only testing your application on Android 4.1 and newer versions of Android, you would set your `minSdkVersion` to be `16`. The initial value is what you requested when you had Android Studio create the project.

You can also specify a `targetSdkVersion`. This indicates what version of Android you are thinking of as you are writing your code. If your application is run on a newer version of Android, Android may do some things to try to improve compatibility of your code with respect to changes made in the newer Android. Nowadays, most Android developers should specify a target SDK version of `15` or higher. We will start to explore more about the `targetSdkVersion` as we get deeper into the book; for the moment, whatever your IDE gives you as a default value is probably a fine starting point.

Version Code and Version Name

Similarly, the `defaultConfig` closure has `versionCode` and `versionName` properties. In principle, these override `android:versionName` and `android:versionCode` attributes on the root `<manifest>` element in the manifest, though you will not find many projects using those XML attributes.

These two values represent the versions of your application. The `versionName` value is what the user will see for a version indicator in the Applications details screen for your app in their Settings application. Also, the version name is used by the Play Store listing, if you are distributing your application that way. The version name can be any string value you want.

The `versionCode`, on the other hand, must be an integer, and newer versions must have higher version codes than do older versions. Android and the Play Store will compare the version code of a new APK to the version code of an installed application to determine if the new APK is indeed an update. The typical approach is to start the version code at `1` and increment it with each production release of your application, though you can choose another convention if you wish. During development, you can leave these alone, but when you move to production, these attributes will matter greatly.

Other Gradle Items of Note

The `android` closure has a `compileSdkVersion` property. `compileSdkVersion` specifies the API level to be compiled against, usually as a simple API level integer (e.g., 19). This indicates what Java classes, methods, and so on are available to you when you write your app. Typically, you set this to be the latest production release of Android, using the values noted earlier in the book.

The `android` closure *may* have a `buildToolsVersion` property. `buildToolsVersion` indicates the version of the Android SDK build tools that you wish to use with this project. The Android Gradle Plugin really is a thin wrapper around a series of "build tools" that handle most of the work of creating an APK out of your project. If your `android` closure does not have `buildToolsVersion`, the Android Gradle Plugin will use its own default version of these build tools, and for many projects this will suffice. In this book, most projects will state their `buildToolsVersion`, though some will skip that line and use the plugin-provided default.

Where's the GUI?

You might wonder why we have to slog through all of this Groovy code and wonder if there is some GUI for affecting Gradle settings.

The answer is yes... and no.

There is the project structure dialog, that allows you to maintain some of this stuff. And you are welcome to try it. However, the more complex your build becomes, the more likely it is that the GUI will not suffice, and you will need to work with the Gradle build files more directly. Hence, this book will tend to focus on the build files.

The Rest of the Manifest

Not everything in the manifest can be overridden in the Gradle build files. Here are a few key items that will always be defined in the manifest, not in a `build.gradle` file.

An Application For Your Application

In your initial project's manifest, the primary child of the `<manifest>` element is an `<application>` element.

By default, when you create a new Android project, you get a single `<activity>` element inside the `<application>` element:

```
<?xml version="1.0" encoding="utf-8"?>
<manifest package="com.commonsware.myapplication"
  xmlns:android="http://schemas.android.com/apk/res/android">

  <application
```

```
    android:allowBackup="true"
    android:icon="@mipmap/ic_launcher"
    android:label="@string/app_name"
    android:roundIcon="@mipmap/ic_launcher_round"
    android:supportsRtl="true"
    android:theme="@style/AppTheme">
    <activity android:name="MainActivity">
      <intent-filter>
        <action android:name="android.intent.action.MAIN" />

        <category android:name="android.intent.category.LAUNCHER" />
      </intent-filter>
    </activity>
  </application>

</manifest>
```

The `<activity>` element supplies `android:name` for the class implementing the activity, `android:label` for the display name of the activity, and (sometimes) an `<intent-filter>` child element describing under what conditions this activity will be displayed. The stock `<activity>` element sets up your activity to appear in the launcher, so users can choose to run it. As we'll see later in this book, you can have several activities in one project, if you so choose.

The `android:name` attribute, in this case, has a bare Java class name (`MainActivity`). Sometimes, you will see `android:name` with a fully-qualified class name (e.g., `com.commonsware.myapplication.MainActivity`). Sometimes, you will see a Java class name with a single dot as a prefix (e.g., `.MainActivity`). Both `MainActivity` and `.MainActivity` refer to a Java class that will be in your project's package — the one you declared in the `package` attribute of the `<manifest>` element.

Supporting Multiple Screens

Android devices come with a wide range of screen sizes, from 2.8" tiny smartphones to 46" TVs. Android divides these into four buckets, based on physical size and the distance at which they are usually viewed:

1. Small (under 3")
2. Normal (3" to around 4.5")
3. Large (4.5" to around 10")
4. Extra-large (over 10")

By default, your application will support small and normal screens. It also will support large and extra-large screens via some automated conversion code built into Android.

To truly support all the screen sizes you want, you should consider adding a `<supports-screens>` element to your manifest. This enumerates the screen sizes you have explicit support for. For example, if you are providing custom UI support for large or extra-large screens, you will want to have the `<supports-screens>` element. So, while the starting manifest file works, handling multiple screen sizes is something you will want to think about.

You wind up with an element akin to:

```
<supports-screens
  android:largeScreens="true"
  android:normalScreens="true"
  android:smallScreens="false"
  android:xlargeScreens="true" />
```

Much more information about providing solid support for all screen sizes, including samples of the `<supports-screens>` element, will be found later in this book as we cover large-screen strategies.

Other Stuff

As we proceed through the book, you will find other elements being added to the manifest, such as:

- `<uses-permission>`, to tell the user that you need permission to use certain device capabilities, such as accessing the Internet
- `<uses-feature>`, to tell Android that you need the device to have certain features (e.g., a camera), and therefore your app should not be installed on devices lacking such features
- `<meta-data>`, for bits of information needed by particular extensions to Android, such as by `FileProvider`.

These and other elements will be introduced elsewhere in the book.

Learning More About Gradle

This book will go into more about Gradle, both in the core chapters and in the trails. But, the focus will be on the Android Gradle Plugin, and Gradle itself offers a lot more than that. The Gradle Web site hosts documentation, links to Gradle-specific books, and links to other Gradle educational resources.

Visit the Trails!

There are a few more chapters in this book getting into more details about the use of Gradle and the Android Gradle Plugin.

- Gradle and Tasks explains how we ask Gradle to do things on our behalf ("tasks"), such as compile our APK for us
- Gradle and Build Variants gets into what capabilities we get from the Gradle project structure, including the ability to configure "build types" and "product flavors"

There is also the "Advanced Gradle for Android Tips" chapter for other Gradle topics, and the chapter on manifest merging in Gradle.

Tutorial #3 - Manifest Changes

As we build `EmPubLite`, we will need to make a number of changes to our project's manifest. In this tutorial, we will take care of a couple of these changes, to show you how to manipulate the `AndroidManifest.xml` file. Future tutorials will make yet more changes.

Android Studio users will also get their first chance to work with the `build.gradle` file.

This is a continuation of the work we did in the previous tutorial.

You can find the results of the previous tutorial and the results of this tutorial in the book's GitHub repository.

Some Notes About Relative Paths

In these tutorials, you will see references to relative paths, like `AndroidManifest.xml`, `res/layout/`, and so on.

You should interpret these paths as being relative to the `app/src/main/` directory within the project, except as otherwise noted. So, for example, Step #1 below will ask you to open `AndroidManifest.xml` — that file can be found in `app/src/main/AndroidManifest.xml` from the project root.

Step #1: Supporting Screens

Our application will restrict its supported screen sizes. Tablets make for ideal ebook readers. Phones can also be used, but the smaller the phone, the more difficult it

will be to come up with a UI that will let the user do everything that is needed, yet still have room for more than a sentence or two of the book at a time.

We will get into screen size strategies and their details later in this book. For the moment, though, we will add a `<supports-screens>` element to keep our application off "small" screen devices (under 3" diagonal size).

Android Studio users can double-click on `AndroidManifest.xml` in the project explorer.

As a child of the root `<manifest>` element, add a `<supports-screens>` element as follows:

```
<supports-screens
    android:largeScreens="true"
    android:normalScreens="true"
    android:smallScreens="false"
    android:xlargeScreens="true"/>
```

Step #2: Blocking Backups

If you look at the `<application>` element, you will see that it has a few attributes, including `android:allowBackup="true"`. This attribute indicates that EmPubLite should participate in Android's automatic backup system.

That is not a good idea, until you understand the technical and legal ramifications of that choice, which we will explore much later in this book.

In the short term, change `android:allowBackup` to be `false`.

Step #3: Ignoring Lint

Even after that change, the `application` element name may have a beige background. If you hover your mouse over it and look at the explanatory tooltip, you will see that it is complaining that this app is not indexable, and that you should add an `ACTION_VIEW` activity to the app.

This is ridiculous. This app (hopefully) will never wind up on the Play Store, and so Google's "app indexing" capability will never be relevant.

Put your text cursor somewhere inside the `application` element name and press Alt-Enter (or Option-Return on macOS). This should bring up a popup window showing some "quick fixes" for the problem:

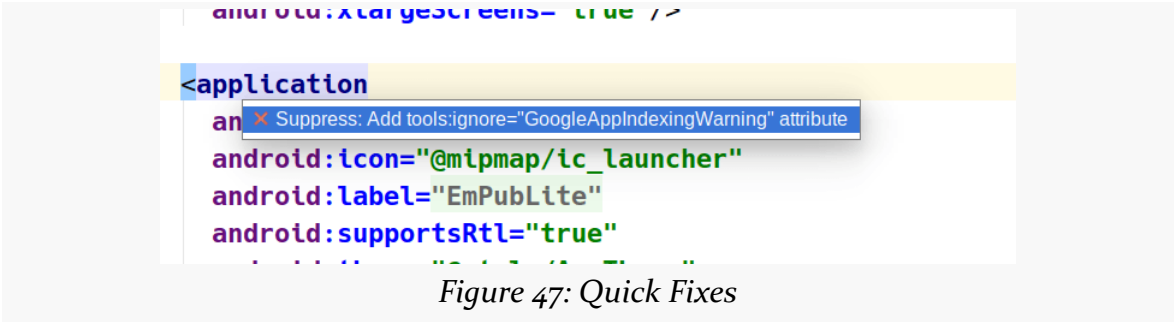

Figure 47: Quick Fixes

Choose the "suppress" option. Then, press Ctrl-Alt-L (or Command-Option-L on macOS) to reformat the file. You will wind up with something like:

```
<?xml version="1.0" encoding="utf-8"?>
<manifest package="com.commonsware.empublite"
  xmlns:android="http://schemas.android.com/apk/res/android"
  xmlns:tools="http://schemas.android.com/tools">

  <supports-screens
    android:largeScreens="true"
    android:normalScreens="true"
    android:smallScreens="false"
    android:xlargeScreens="true" />

  <application
    android:allowBackup="false"
    android:icon="@mipmap/ic_launcher"
    android:label="@string/app_name"
    android:supportsRtl="true"
    android:theme="@style/AppTheme"
    tools:ignore="GoogleAppIndexingWarning">
    <activity android:name=".EmPubLiteActivity">
      <intent-filter>
        <action android:name="android.intent.action.MAIN" />

        <category android:name="android.intent.category.LAUNCHER" />
      </intent-filter>
    </activity>
  </application>

</manifest>
```

(from EmPubLite-AndroidStudio/T3-Manifest/EmPubLite/app/src/main/AndroidManifest.xml)

The `<application>` element now has a `tools:ignore="GoogleAppIndexingWarning"` attribute, and the root `<manifest>` element defines the `tools` XML namespace. The net effect is that we are telling the build tools — specifically the Lint utility – that it should ignore this particular issue.

In Our Next Episode…

… we will make some changes to the resources of our tutorial project

Some Words About Resources

It is quite likely that by this point in time, you are "chomping at the bit" to get into actually writing some code. This is understandable. That being said, before we dive into the Java source code for our stub project, we really should chat briefly about resources.

Resources are static bits of information held outside the Java source code. As we discussed previously, resources are stored as files under the `res/` directory in your source set (e.g., `app/src/main/res/`). Here is where you will find all your icons and other images, your externalized strings for internationalization, and more.

These are separate from the Java source code not only because they are different in format. They are separate because you can have *multiple* definitions of a resource, to use in different circumstances. For example, with internationalization, you will have strings for different languages. Your Java code will be able to remain largely oblivious to this, as Android will choose the right resource to use, from all candidates, in a given circumstance (e.g., choose the Spanish string if the device's locale is set to Spanish).

We will cover all the details of these resource sets later in the book. Right now, we need to discuss the resources in use by our stub project, plus one more.

This chapter will refer to the `res/` directory as a shorthand for the `app/src/main/res/` directory of the project.

String Theory

Keeping your labels and other bits of text outside the main source code of your application is generally considered to be a very good idea. In particular, it helps with

internationalization (I18N) and localization (L10N). Even if you are not going to translate your strings to other languages, it is easier to make corrections if all the strings are in one spot instead of scattered throughout your source code.

Plain Strings

Generally speaking, all you need to do is have an XML file in the `res/values` directory (typically named `res/values/strings.xml`), with a `resources` root element, and one child `string` element for each string you wish to encode as a resource. The `string` element takes a `name` attribute, which is the unique name for this string, and a single text element containing the text of the string:

```
<resources>
  <string name="quick">The quick brown fox...</string>
  <string name="laughs">He who laughs last...</string>
</resources>
```

One tricky part is if the string value contains a quote or an apostrophe. In those cases, you will want to escape those values, by preceding them with a backslash (e.g., `These are the times that try men\'s souls`). Or, if it is just an apostrophe, you could enclose the value in quotes (e.g., `"These are the times that try men's souls."`).

For example, a project's `strings.xml` file could look like this:

```
<resources>
  <string name="app_name">EmPubLite</string>
</resources>
```

(from EmPubLite-AndroidStudio/T3-Manifest/EmPubLite/app/src/main/res/values/strings.xml)

We can reference these string resources from various locations, in our Java source code and elsewhere. For example, the `app_name` string resource often is used in the `AndroidManifest.xml` file:

```
<?xml version="1.0" encoding="utf-8"?>
<manifest package="com.commonsware.empublite"
  xmlns:android="http://schemas.android.com/apk/res/android"
  xmlns:tools="http://schemas.android.com/tools">

  <supports-screens
    android:largeScreens="true"
    android:normalScreens="true"
    android:smallScreens="false"
```

```
    android:xlargeScreens="true" />

  <application
    android:allowBackup="false"
    android:icon="@mipmap/ic_launcher"
    android:label="@string/app_name"
    android:supportsRtl="true"
    android:theme="@style/AppTheme"
    tools:ignore="GoogleAppIndexingWarning">
    <activity android:name=".EmPubLiteActivity">
      <intent-filter>
        <action android:name="android.intent.action.MAIN" />

        <category android:name="android.intent.category.LAUNCHER" />
      </intent-filter>
    </activity>
  </application>

</manifest>
```

(from EmPubLite-AndroidStudio/T3-Manifest/EmPubLite/app/src/main/AndroidManifest.xml)

Here, the `android:label` attribute of the `<application>` element refers to the `app_name` string resource. This will appear in a few places in the application, notably in the list of installed applications in Settings. So, if you wish to change how your application's name appears in these places, simply adjust the `app_name` string resource to suit.

The syntax `@string/app_name` tells Android "find the string resource named `app_name`". This causes Android to scan the appropriate `strings.xml` file (or any other file containing string resources in your `res/values/` directory) to try to find `app_name`.

Um, Wait, My Manifest Does Not Look Like That

When you view a manifest like that in Android Studio, it may appear as though you are not using resources, as you may not see `@string/...` references:

```
<application
  android:allowBackup="false"
  android:icon="@mipmap/ic_launcher"
  android:label="EmPubLite"
  android:supportsRtl="true"
  android:theme="@style/AppTheme"
  tools:ignore="GoogleAppIndexingWarning">
  <activity android:name=".EmPubLiteActivity">
    <intent-filter>
      <action android:name="android.intent.action.MAIN" />

      <category android:name="android.intent.category.LAUNCHER" />
    </intent-filter>
  </activity>
</application>
```

Figure 48: AndroidManifest.xml, As Initially Viewed in Android Studio

Here, `android:label` looks as though it is the hard-coded value "EmPubLite".

However, notice that the attribute value is formatted differently than the others. The rest are green text with a white background, while this one is gray text with a shaded background.

That is because Android Studio is lying to you.

If you hover your mouse over the value, you will see the *real* attribute appear just below it:

```
<application
  android:allowBackup="false"
  android:icon="@mipmap/ic_launcher"
  android:label="EmPubLite"
  android:label="@string/app_name"
  android:theme="@style/AppTheme"
  tools:ignore="GoogleAppIndexingWarning">
  <activity android:name=".EmPubLiteActivity">
    <intent-filter>
      <action android:name="android.intent.action.MAIN" />

      <category android:name="android.intent.category.LAUNCHER" />
    </intent-filter>
  </activity>
</application>
```

Figure 49: AndroidManifest.xml, With Mouse Hovering Over "EmPubLite"

And, if you click on the fake value, you will see the real XML, with the real string resource value.

What is happening is that Android Studio, by default, will substitute a candidate value for the resource in its presentation of the manifest, other resources that refer to resources, and even Java code. Any time you see that gray-on-light-blue formatting, remember that this is not the real value, and that you have to uncover the real value via hovering over it or clicking on it.

Styled Text

Many things in Android can display rich text, where the text has been formatted using some lightweight HTML markup: `<b>`, `<i>`, and `<u>`. Your string resources support this, simply by using the HTML tags as you would in a Web page:

```
<resources>
  <string name="b">This has <b>bold</b> in it.</string>
  <string name="i">Whereas this has <i>italics</i>!</string>
</resources>
```

CDATA. CDATA Run. Run, DATA, Run.

Since a strings resource XML file is an XML file, if your message contains <, >, or & characters (other than the formatting tags listed above), you will need to use a `CDATA` section:

```
<string name="report_body">
<![CDATA[
<html>
<body>
<h1>TPS Report for: {{reportDate}}</h1>
<p>Here are the contents of the TPS report:</p>
<p>{{message}}</p>
<p>If you have any questions regarding this report, please
do <b>not</b> ask Mark Murphy.</p>
</body>
</html>
]]>
  </string>
```

The Directory Name

Our string resources in our stub project are in the `res/values/strings.xml` file. Since this directory name (`values`) has no suffixes, the string resources in that directory will be valid for any sort of situation, including any locale for the device. We will need additional directories, with distinct `strings.xml` files, to support other languages. We will cover how to do that later in this book.

Editing String Resources

If you double-click on a string resource file, like `res/values/strings.xml`, in Android Studio, you are presented the XML and edit it that way. There is an option for entering a dedicated string translation view, covered later in this book.

Multi-Locale Support

Android 7.0+ users can indicate that they support more than one language:

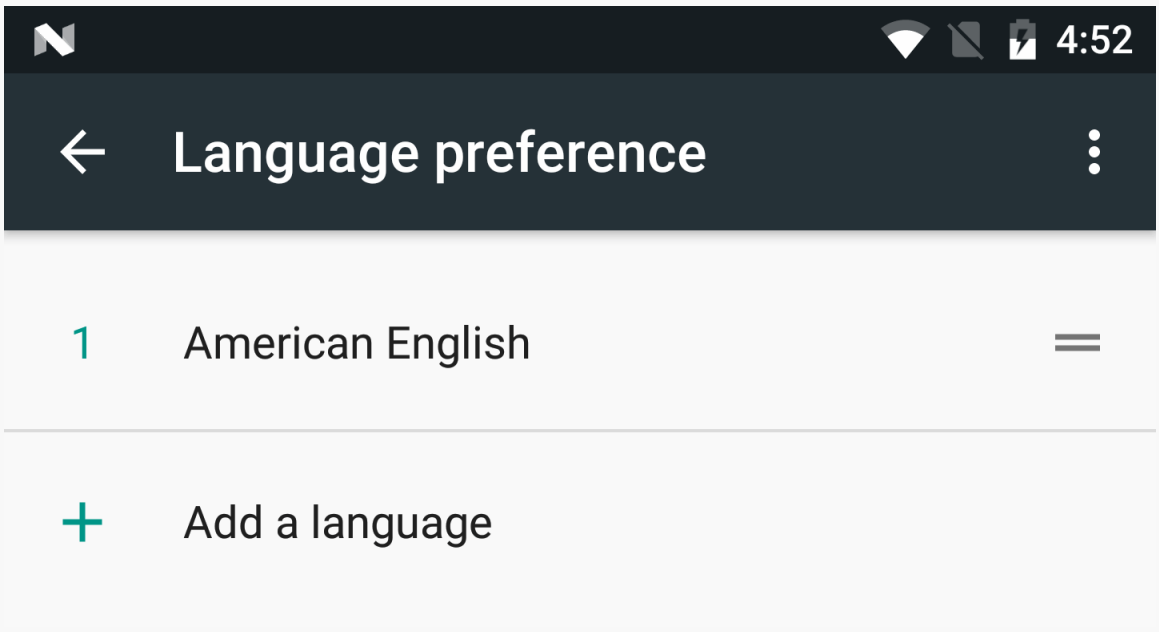

Figure 50: Android 7.0 Language Settings

The user can choose the relative priorities of these languages, by grabbing the handle on the right side of the row and dragging the language higher or lower in the list.

This has impacts on resource resolution for any locale-dependent resources, such as strings. Now Android will check multiple languages for resource matches, before falling back to the default language (e.g., whatever you have in `res/values/strings.xml`). Hence, it is important that you ensure that you have a complete set of strings for every language that you support, lest the user perhaps wind up with a mixed set of languages in the UI.

You can find out what languages the user has requested via a `LocaleList` class and its `getDefault()` `static` method. This, as the name suggests, has a list of `Locale` objects representing the user's preferred languages. If you had previously been using `Locale` alone for this (e.g., for specialized in-app language assistance beyond resources), you will want to switch to `LocaleList` for Android 7.0 and beyond.

Got the Picture?

All Android versions support images in the PNG, JPEG, and GIF formats. GIF is officially discouraged, however; PNG is the overall preferred format. Android also

supports some proprietary XML-based image formats, though we will not discuss those at length until later in the book. Many newer versions of Android also support Google's WebP image format, though this is not especially popular.

There are two types of resources that use images like these: drawables and mipmaps. In truth, they are nearly identical. Mipmaps are used mostly for "launcher icons" — the icons seen in home screen launchers that identify activities that the user can start. Drawables hold everything else.

(if you are a seasoned Android developer and are reading this section: while drawable resources might be removed when packaging an APK, such as for the Android Gradle Plugin `split` system for making density-specific editions of an app, mipmap resources are left alone, apparently)

It is possible to have `res/drawable/` and `res/mipmap/` directories in an Android module. However, you will not find bitmaps there usually. Instead, those reside in directories like `res/drawable-mdpi/` and `res/drawable-hdpi/`.

These refer to distinct resource sets. The suffixes (e.g., `-mdpi`, `-hdpi`) are filters, indicating under what circumstances the images stored in those directories should be used. Specifically, `-ldpi` indicates images that should be used on devices with low-density screens (around 120 dots-per-inch, or "dpi"). The `-mdpi` suffix indicates resources for medium-density screens (around 160dpi), `-hdpi` indicates resources for high-density screens (around 240dpi). `-xhdpi` indicates resources for extra-high-density screens (around 320dpi), `-xxhdpi` indicates extra-extra-high-density screens (around 480dpi), `-xxxhdpi` indicates extra-extra-extra-high-density screens (around 640dpi), and so on.

In the `EmPubLite` tutorial project, you will find a series of `mipmap` directories with the same sorts of suffixes (e.g., `res/mipmap-hdpi`). Inside each of those directories, you will see an `ic_launcher.png` file. This is the stock icon that will be used for your application in the home screen launcher. Each of the images is of the same icon, but the higher-density icons have more pixels. The objective is for the image to be roughly the same physical size on every device, using higher densities to have more detailed images.

Our `AndroidManifest.xml` file then references our `ic_launcher` icon in the `<application>` element:

```
<?xml version="1.0" encoding="utf-8"?>
<manifest package="com.commonsware.empublite"
```

```
  xmlns:android="http://schemas.android.com/apk/res/android"
  xmlns:tools="http://schemas.android.com/tools">

  <supports-screens
    android:largeScreens="true"
    android:normalScreens="true"
    android:smallScreens="false"
    android:xlargeScreens="true" />

  <application
    android:allowBackup="false"
    android:icon="@mipmap/ic_launcher"
    android:label="@string/app_name"
    android:supportsRtl="true"
    android:theme="@style/AppTheme"
    tools:ignore="GoogleAppIndexingWarning">
    <activity android:name=".EmPubLiteActivity">
      <intent-filter>
        <action android:name="android.intent.action.MAIN" />

        <category android:name="android.intent.category.LAUNCHER" />
      </intent-filter>
    </activity>
  </application>

</manifest>
```

(from EmPubLite-AndroidStudio/T3-Manifest/EmPubLite/app/src/main/AndroidManifest.xml)

Note that the manifest simply refers to `@mipmap/ic_launcher`, telling Android to find a mipmap resource named `ic_launcher`. The resource reference does not indicate the file type of the resource — there is no `.png` in the resource identifier. This means you cannot have `ic_launcher.png` and `ic_launcher.jpg` in the same project, as they would both be identified by the same identifier. You will need to keep the "base name" (filename sans extension) distinct for all of your images.

Also, the `@mipmap/ic_launcher` reference does not mention what screen density to use. That is because *Android* will choose the right screen density to use, based upon the device that is running your app. You do not have to worry about it explicitly, beyond having multiple copies of your icon. If Android detects that the device has a screen density for which you lack an icon, Android will take the next-closest one and scale it.

Some Notes About WebP

Android 4.0 added partial support for Google's WebP image format, and Android 4.3 devices support the previously-missing features (lossless compression and transparency). WebP serves as a replacement for both PNG and JPEG, and in some circumstances it can result in smaller on-disk sizes for near-equivalent image quality.

Android Studio, starting with version 2.3, has special support to help you convert drawable resources and other images from JPEG and PNG to WebP. Simply right-click over the image in the project tree and choose "Convert to WebP" from the context menu.

Initially, you are given a window for controlling the quality and output:

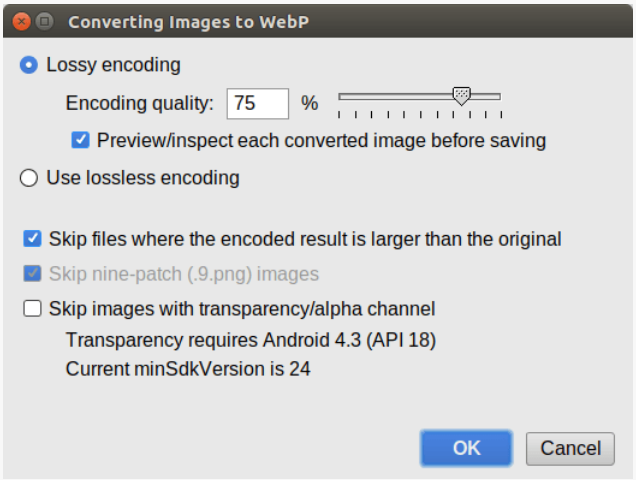

Figure 51: WebP Converter in Android Studio

"Lossy encoding" refers to the type performed by JPEG, taking into account that humans have limited ability to distinguish similar colors to achieve tighter compression. "Lossless encoding" refers to the type performed by PNG, where the compressed image is identical to the original, just as a ZIP file's contents are identical to the files before they were ZIPped. For lossy encoding, you can choose a quality percentage, where higher quality images will not compress as well.

You can also:

- Skip anything that results in a *bigger* image (as sometimes WebP will be bigger than the JPEG or PNG equivalent)

- Skip a type of PNG called a nine-patch PNG, used for widget backgrounds
- Skip images that use transparency, in case your `minSdkVersion` will not support such images

If you choose lossy compression and leave the "preview" checkbox checked, you are then presented with a window showing the results of the conversion at your requested quality level:

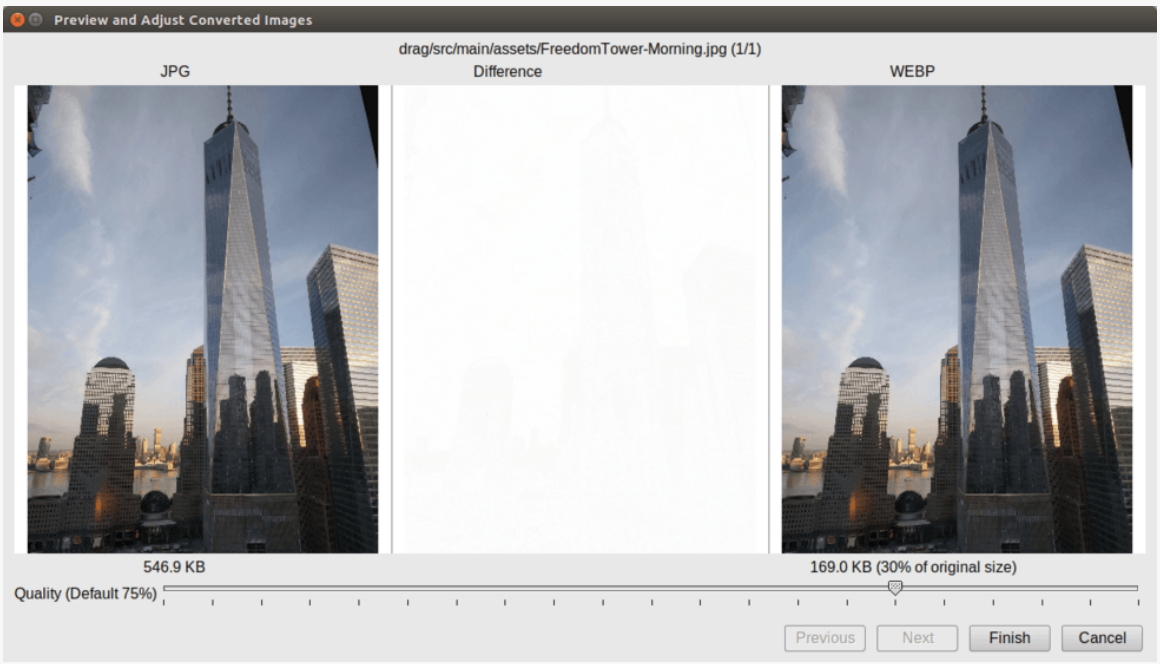

Figure 52: WebP Conversion Preview

You can adjust the quality slider below the images to see how the image changes with different quality levels and how much additional disk savings you will get from the WebP conversion.

When you are done, the WebP converter will replace your old PNG or JPEG file with the converted WebP image.

Dimensions

Dimensions are used in several places in Android to describe distances, such as a widget's size. There are several different units of measurement available to you:

1. `px` means hardware pixels, whose size will vary by device, since not all devices have the same screen density
2. `in` and `mm` for inches and millimeters, respectively, based on the actual size of the screen
3. `pt` for points, which in publishing terms is 1/72nd of an inch (again, based on the actual physical size of the screen)
4. `dip` (or `dp`) for density-independent pixels — one `dip` equals one hardware pixel for a ~160dpi resolution screen, but one `dip` equals two hardware pixels on a ~320dpi screen
5. `sp` for scaled pixels, where one `sp` equals one `dip` for normal font scale levels, increasing and decreasing as needed based upon the user's chosen font scale level in Settings

Dimension resources, by default, are held in a `dimens.xml` file in the `res/values/` directory that also holds your strings.

To encode a dimension as a resource, add a `dimen` element to `dimens.xml`, with a `name` attribute for your unique name for this resource, and a single child text element representing the value:

```
<resources>
  <dimen name="thin">10dip</dimen>
  <dimen name="fat">1in</dimen>
</resources>
```

In a layout, you can reference dimensions as `@dimen/...`, where the ellipsis is a placeholder for your unique name for the resource (e.g., `thin` and `fat` from the sample above). In Java, you reference dimension resources by the unique name prefixed with `R.dimen.` (e.g., `Resources.getDimension(R.dimen.thin)`).

While our stub project does not use dimension resources, we will be seeing them soon enough.

Editing Dimension Resources

As with most types of XML resources, Android Studio just has you edit the XML directly, when you double-click on the resource in the project explorer.

The Resource That Shall Not Be Named… Yet

Your stub project also has a `res/layout/` directory, in addition to the ones described above. That is for UI layouts, describing what your user interface should look like. We will get into the details of that type of resource as we start examining our user interfaces in an upcoming chapter.

Icons

Icons are `drawable` resources. Except when they are `mipmap` resources. And except when they are multiple resources, combined together at runtime to create an image with a "squircle" background. And...

Are you confused yet?

In theory, setting up icons for your app would be quite simple, and for years that was the case. Nowadays, setting up an app icon is unnecessarily complex, though at least Android Studio has an Asset Studio tool to try to make it a bit simpler.

In this chapter, we will explore what it takes to set up one of these app icons.

App Icons… And Everything Else

Each app has an icon. This is used for places like the list of installed apps in Settings. Traditionally — and to reduce user confusion — this icon is also used for the home screen launcher.

Google has been making this icon increasingly complicated over the past few years:

- App icons are `mipmap` resources, while everything else is a `drawable` resource
- Android 7.1 introduced the concept of a separate "round icon" that an app can have, which would be used in place of the regular app icon on certain Android 7.1 devices... then dropped this feature with Android 8.0
- Android 8.0 introduced the concept of "adaptive icons", where you have to provide separate "foreground" and "background" images, mostly so that certain home screen launchers can shape the background image as they want (square, round, "squircle", etc.)

Most other icons — other than notification icons – are comparatively straightforward.

Creating an App Icon with the Asset Studio

If you right-click over pretty much any directory in the Android Studio tree, the context menu will have an "Image Asset" option. This is also available from File > New > Image Asset. This brings up the Asset Studio, to help you to assemble icons.

By default, the Asset Studio has its "Icon Type" drop-down set for "Launcher Icons (Adaptive and Legacy)", which is how you set up an app icon nowadays:

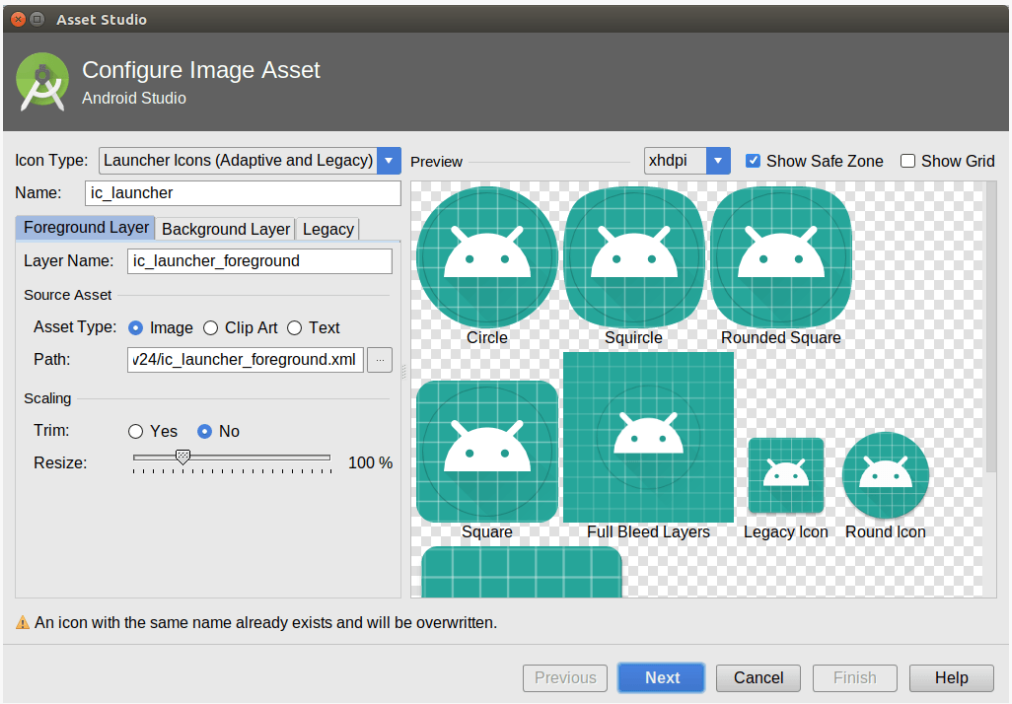

Figure 53: Asset Studio, As Initially Launched

The overall name for your launcher icon is found in the Name field, above the tabs. The default is `ic_launcher`, and unless you have a good reason to change it, you are best served by leaving it alone.

Foreground Layer

What you would ordinarily think of as your icon is what Android Studio and Android 8.0+ refer to as the "Foreground Layer". The Asset Studio starts on the Foreground Layer tab for you to configure this layer.

Your icon can come from three main sources:

- Some image of your own design, which you would load into the Foreground Layer tab by selecting the Image radio button, then clicking the "..." button next to the Path field, to browse your development machine and find that image
- A piece of canned clip art, which you would choose by clicking on the "Clip Art" radio button, clicking the "Clip Art" button to choose the image, and clicking the Color button to choose a color to apply to that image:

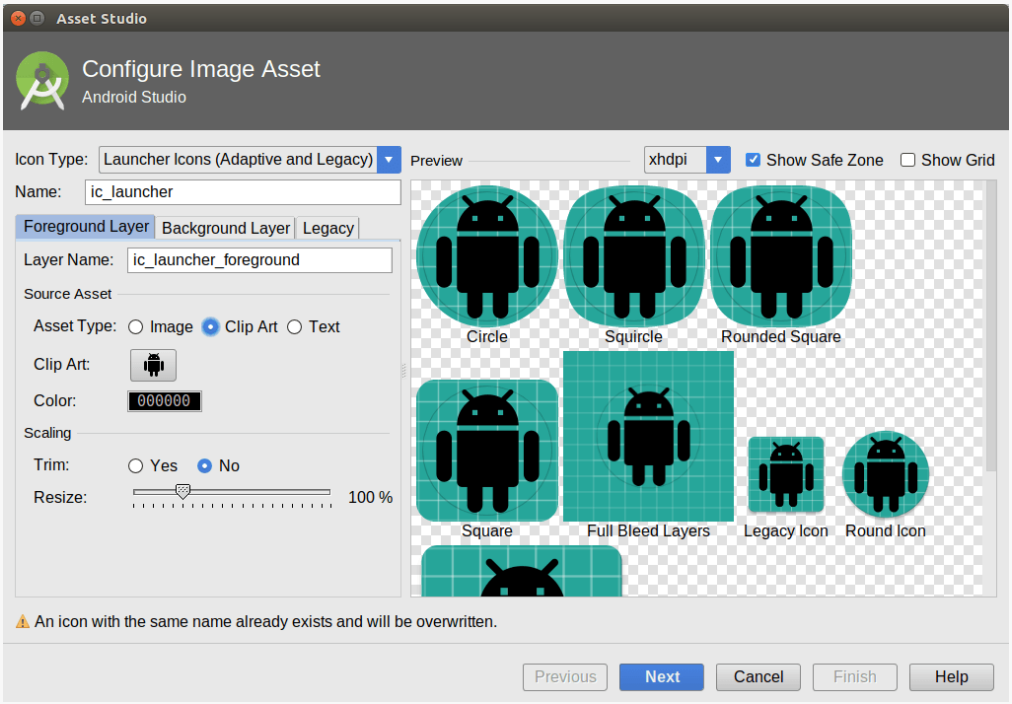

Figure 54: Asset Studio, Showing Clip Art Options

- A letter or two, which you would choose by clicking on the Text radio button, filling in 1-2 letters in the Text field, choosing a font from your development machine in the adjacent drop-down, and clicking the Color button to choose a color to apply to the font:

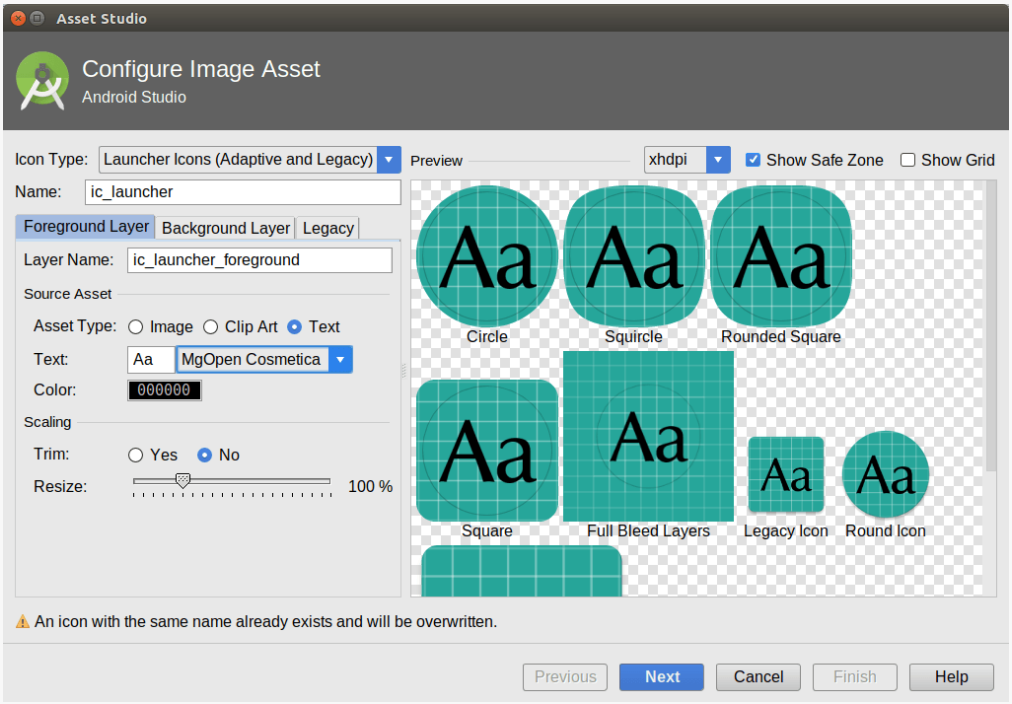

Figure 55: Asset Studio, Showing Text Options

For all three of these, you can:

- Choose the name to use for this image, in the “Layer Name” field
- Choose, via the Trim radio buttons, whether to remove all transparent space from the edges of the image (“Yes”) or not (“No”)
- Resize the image from its default size

That latter choice is particularly important, as you need to keep your foreground layer content within the “safe zone”. That shows up in the previews as a dark gray circle. So long as your foreground layer is in the safe zone, you should not have to worry about any launcher accidentally cutting off part of the layer when it renders your app icon.

Background Layer

In the preview area, by default, you will see a blue-green grid behind your foreground layer. That is the default background layer. If you would like to use something else, click the “Background Layer” tab:

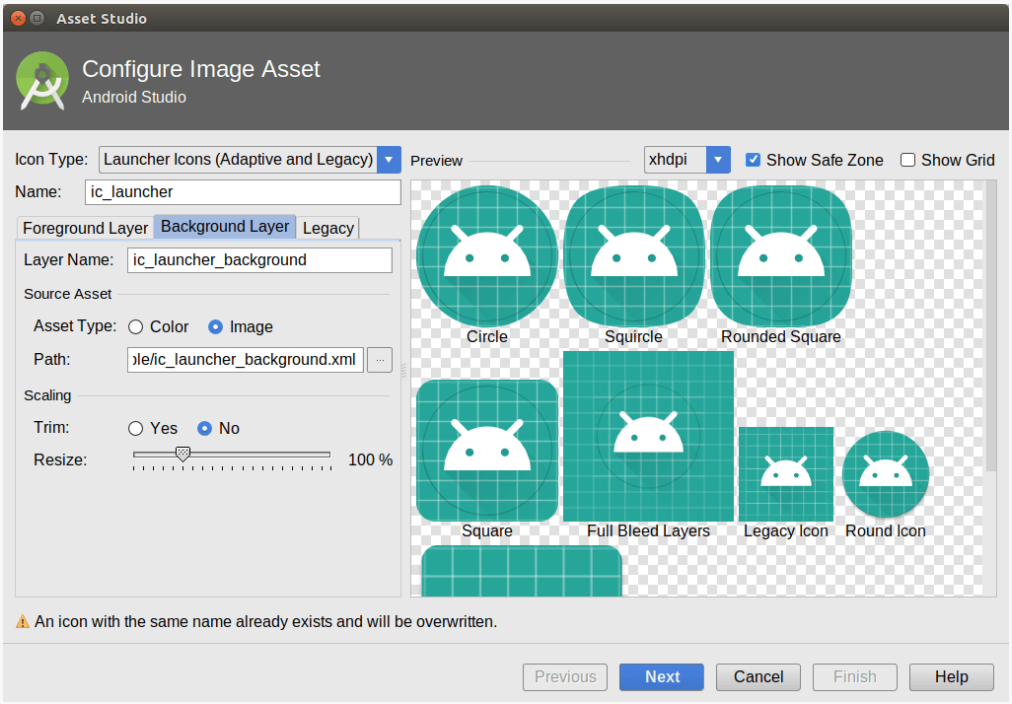

Figure 56: Asset Studio, Showing Background Layer

Your two main options are:

- a flat color
- an image of your choosing (akin to the foreground, where you click the "..." button next to the Path field to pick the background image)

The background needs to be designed to be cropped into a variety of shapes, such as those shown in the preview (circle, various rounded forms of squares, etc.). Hence, outside of flat colors, typical backgrounds will be gradients or simple patterns, such as the default grid.

Legacy

On Android 8.0+ devices, the foreground layer, background layer, and launcher-chosen shape (e.g., squircle) combine to create your app icon.

On older devices, the app icon is whatever you choose it to be, where the Legacy tab helps you decide what that is:

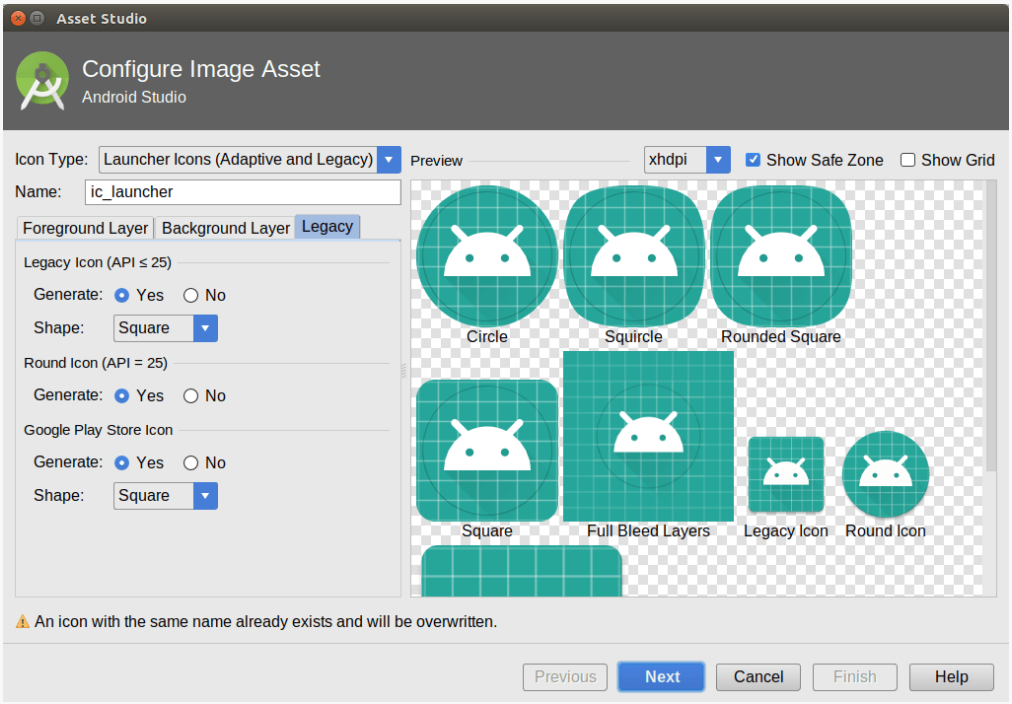

Figure 57: Asset Studio, Showing Legacy Options

The most important legacy option is the "Legacy Icon (API <= 25)" section. If your `minSdkVersion` is below 26, this will be the icon rendition that will be used as your app icon by default. The Asset Studio will merge your foreground and background layers itself, then apply your selected shape from the drop-down (e.g., square).

For Android 7.1 devices, you can also opt to have the Asset Studio create a separate round icon, that you can declare in your manifest, as will be seen later in this chapter.

If you are going to be distributing your app through the Play Store, you can also generate a Play Store rendition of your icon. This is reminiscent of the legacy icon, but at a higher resolution.

Generating the Icon

Once you have adjusted your app icon via the three tabs, click Next at the bottom of the Asset Studio wizard. This will bring up the final wizard page, showing you what will be generated for you by the wizard:

The Output Directories tree shows you each file that will be created or replaced. Those that show up in red are ones that will be replaced; ones that show up in black are new files. Typically, unless you changed the icon or layer names, most of the files will be replacements for files that exist already.

Some of these files will be typical bitmap-style resources. Some are vector drawables.

Using In Your Manifest

Then, in your manifest, you can have `android:icon` and optionally `android:roundIcon` attributes on the `<application>` element to associate your icons with your app. If you did not change the names of the icons, then your manifest should already have the appropriate attribute values.

```
<?xml version="1.0" encoding="utf-8"?>
<manifest package="com.commonsware.myapplication"
  xmlns:android="http://schemas.android.com/apk/res/android">

  <application
    android:allowBackup="true"
    android:icon="@mipmap/ic_launcher"
    android:label="@string/app_name"
    android:roundIcon="@mipmap/ic_launcher_round"
    android:supportsRtl="true"
    android:theme="@style/AppTheme">
    <activity android:name=".MainActivity">
      <intent-filter>
        <action android:name="android.intent.action.MAIN" />

        <category android:name="android.intent.category.LAUNCHER" />
      </intent-filter>
    </activity>
  </application>

</manifest>
```

Creating Other Icons with the Asset Studio

In principle, you can use the Asset Studio to create other types of icons, by choosing another type of icon from the drop down, such as “Action Bar and Tab Icons”.

In practice, the Asset Studio does not do much for you here, other than create multiple versions of your icon for different screen densities.

For most Android app developers, there are two other options:

1. Get icons at the right resolutions for different densities from your graphic designer, perhaps exported from Adobe Photoshop
2. Create vector icons, as will be covered in an upcoming chapter

Tutorial #4 - Adjusting Our Resources

Our `EmPubLite` project has some initial resources. However, the defaults are not what we want for the long term. So, in addition to adding new resources in future tutorials, we will fix the ones we already have in this tutorial.

This is a continuation of the work we did in the previous tutorial.

You can find the results of the previous tutorial and the results of this tutorial in the book's GitHub repository.

Step #1: Changing the Name

Our application shows up everywhere as "EmPubLite":

- In the title bar of our activity
- As the caption under our icon in the home screen launcher
- In the Application list in the Settings app
- And so on

We should change that to be "EmPub Lite", adding a space for easier reading, and to illustrate that this is a "lite" version of the full `EmPub` application.

Double-click on the `res/values/strings.xml` file in your project explorer.

In the XML editor for the string resources, you will find an element that looks like:

```
<string name="app_name">EmPubLite</string>
```

Change the text node in this element to `EmPub Lite`. Then save your changes, giving you something like:

```
<resources>
  <string name="app_name">EmPub Lite</string>
</resources>
```

Step #2: Changing the Icon

The build tools provide us with a stock icon to use for the launcher — the actual image used varies by Android tools release. However, we can change it to something else. For example, we could use the icon portion of the CommonsWare logo:

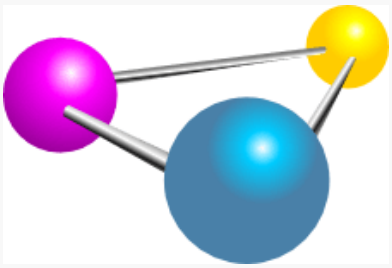

Figure 58: CommonsWare

Download the molecule PNG file from the CommonsWare Web site and save it somewhere on your development machine.

Then, right-click over the `res/` directory in your `main` source set in the project explorer, and choose New > Image Asset from the context menu. That will bring up the Asset Studio wizard:

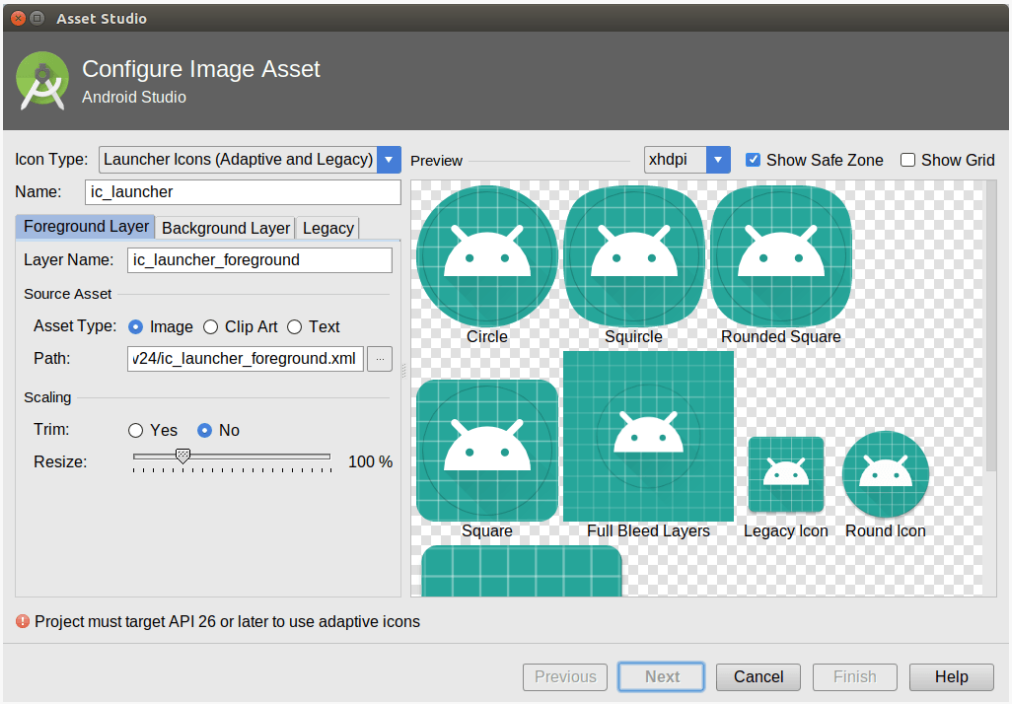

Figure 59: Asset Studio Wizard, First Page

In the Icon Type drop-down, choose “Launcher Icons (Legacy only)”. This will change the wizard to look like:

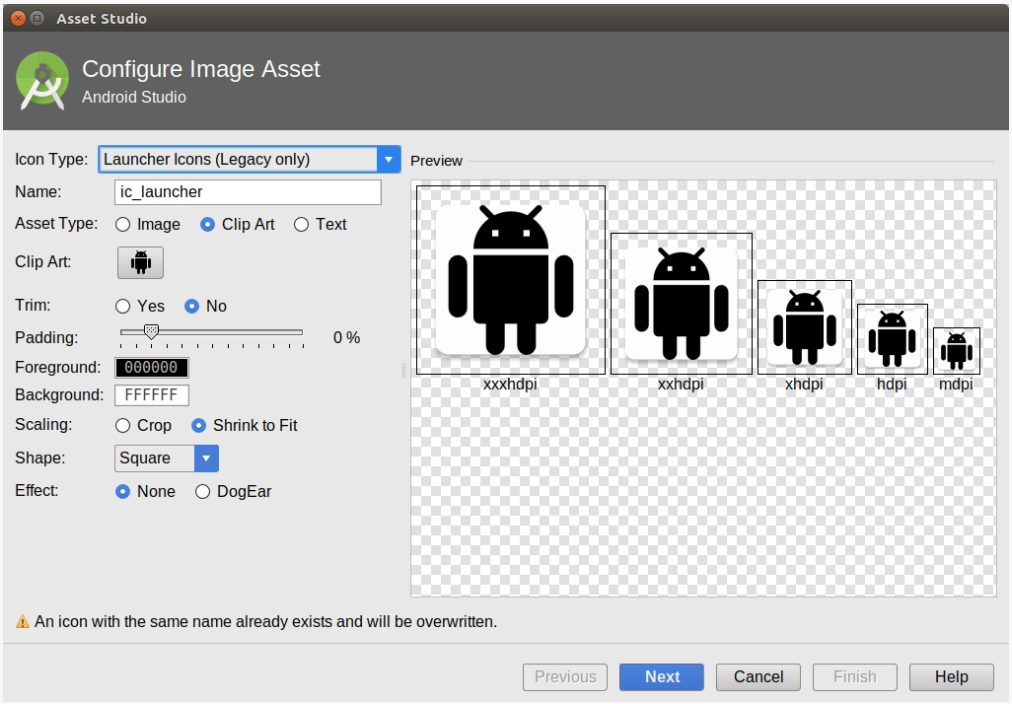

Figure 60: Asset Studio Wizard, First Page, Legacy Mode

Click the "Image" radio button in the "Asset Type" row. Then, click the "..." to the right of the "Path" field and choose the `molecule.png` file that you downloaded. Also, ensure that "Scaling" is set to "Shrink to Fit", and choose "None" from the "Shape" drop-down. This should give you a preview of what the icons will look like:

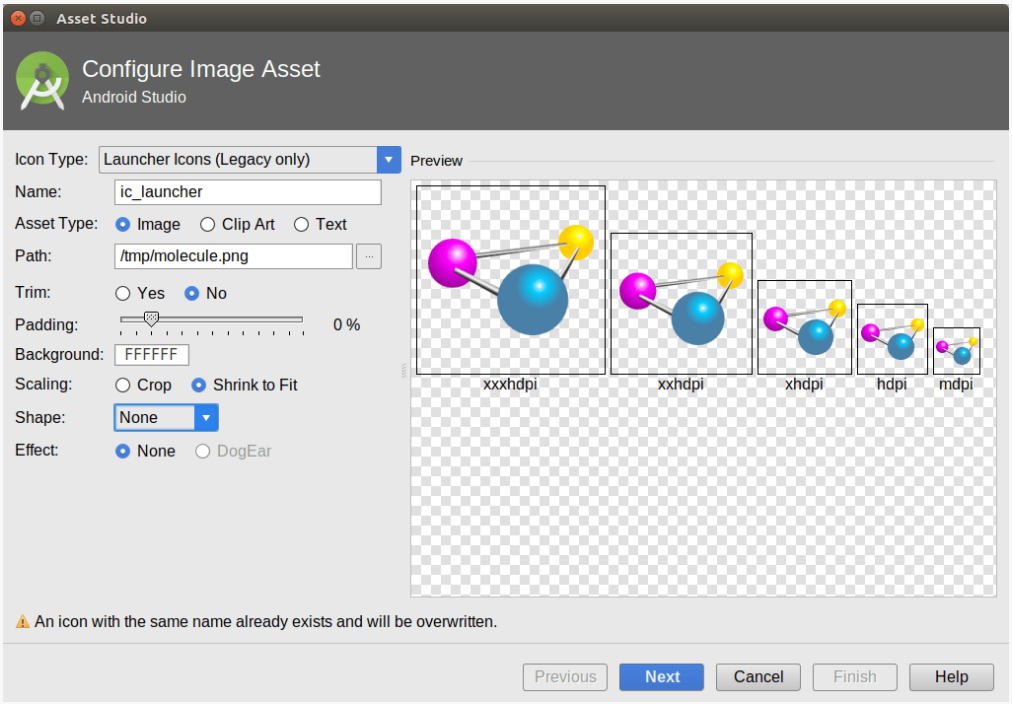

Figure 61: Asset Studio Wizard, First Page, After Loading Image

Leave the rest of the wizard alone, then click Next to proceed to the next page:

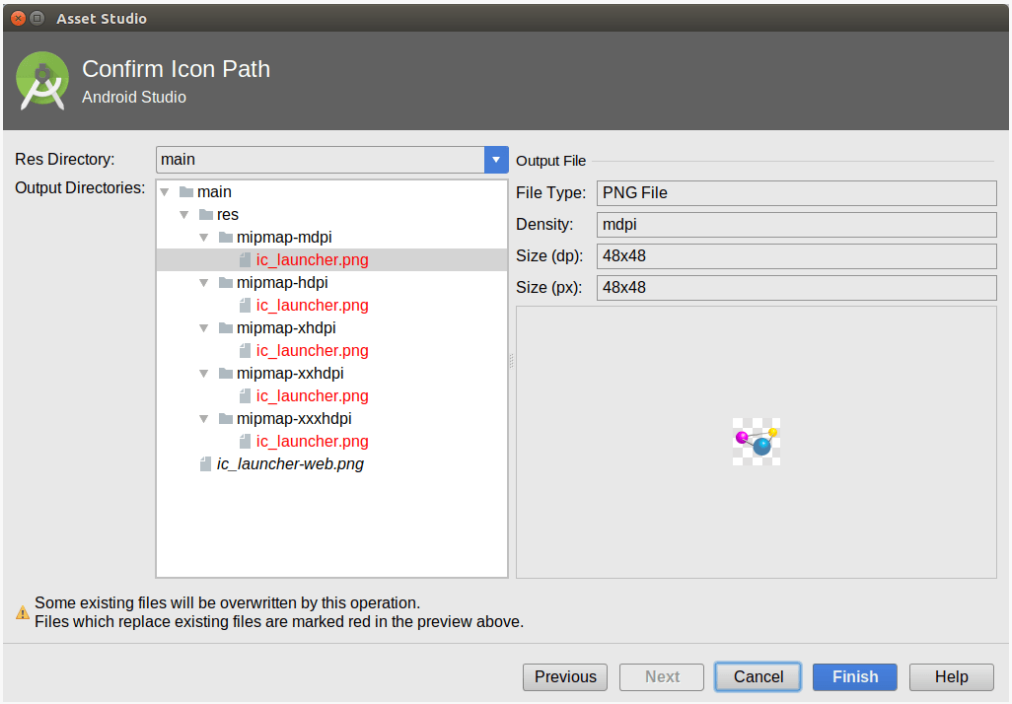

Figure 62: Asset Studio Wizard, Second Page

You should get a warning towards the bottom, indicating that if you finish the wizard, you will overwrite existing files. This is expected, as we are trying to replace the old `ic_launcher.png` files with new ones. So, go ahead and click Finish.

Step #3: Running the Result

If you run the resulting app, you will see that it shows up with the new name and icon, such as in the launcher:

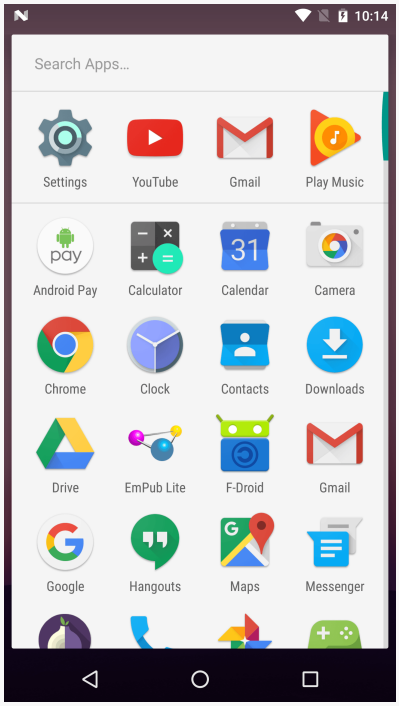

Figure 63: EmPubLite with New Icons

In Our Next Episode…

… we will add a progress indicator to the UI of our tutorial project.

The Theory of Widgets

There is a decent chance that you have already done work with widget-based UI frameworks. In that case, much of this chapter will be review, though checking out the section on the absolute positioning anti-pattern should certainly be worthwhile.

There is a chance, though, that your UI background has come from places where you have not been using a traditional widget framework, where either you have been doing all of the drawing yourself (e.g., game frameworks) or where the UI is defined more in the form of a document (e.g., classic Web development). This chapter is aimed at you, to give you some idea of what we are talking about when discussing the notion of widgets and containers.

What Are Widgets?

Wikipedia has a nice definition of a widget:

> In computer programming, a widget (or control) is an element of a graphical user interface (GUI) that displays an information arrangement changeable by the user, such as a window or a text box. The defining characteristic of a widget is to provide a single interaction point for the direct manipulation of a given kind of data. In other words, widgets are basic visual building blocks which, combined in an application, hold all the data processed by the application and the available interactions on this data.

(quote from the 7 March 2014 version of the page)

Take, for example, this Android screen:

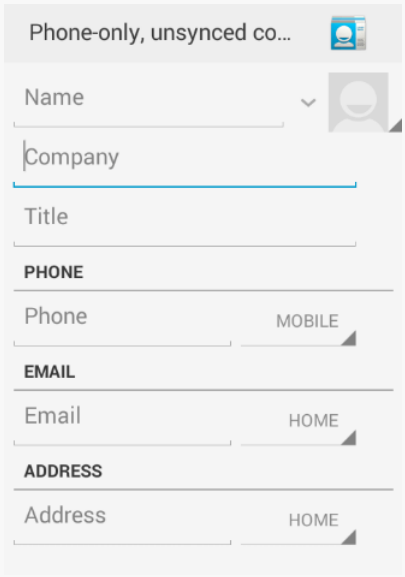

Figure 64: A Sample Android Screen

Here, we see:

- some text, like “Phone-only, unsynced co...” and “PHONE”
- an icon of a contact “Rolodex” card
- some data entry fields with hints like “Name” and “Company”
- some “spinner” drop-down lists (the items with the arrowheads pointing southeast)
- some gray divider lines

Everything listed above is a widget. The user interface for most Android screens (“activities”) is made up of one or more widgets.

This does not mean that you cannot do your own drawing. In fact, all the existing widgets are implemented via low-level drawing routines, which you can use for everything from your own custom widgets to games.

This also does not mean that you cannot use Web technologies. In fact, we will see later in this book a widget designed to allow you to embed Web content into an Android activity.

However, for most non-game applications, your Android user interface will be made up of several widgets.

Size, Margins, and Padding

Widgets have some sort of size, since a zero-pixel-high, zero-pixel-wide widget is not especially user-friendly. Sometimes, that size will be dictated by what is inside the widget itself, such as a label (`TextView`) having a size dictated by the text in the label. Sometimes, that size will be dictated by the size of whatever holds the widget (a "container", described in the next section), where the widget wants to take up all remaining width and/or height. Sometimes, that size will be a specific set of dimensions.

Widgets can have margins. As with CSS, margins provide separation between a widget and anything adjacent to it (e.g., other widgets, edges of the screen). Margins are really designed to help prevent widgets from running right up next to each other, so they are visually distinct. Some developers, however, try to use margins as a way to hack "absolute positioning" into Android, which is an anti-pattern that we will examine later in this chapter.

Widgets can have padding. As with CSS, padding provides separation between the contents of a widget and the widget's edges. This is mostly used with widgets that have some sort of background, like a button, so that the contents of the widget (e.g., button caption) does not run right into the edges of the button, once again for visual distinction.

What Are Containers?

Containers are ways of organizing multiple widgets into some sort of structure. Widgets do not naturally line themselves up in some specific pattern — we have to define that pattern ourselves.

In most GUI toolkits, a container is deemed to have a set of children. Those children are widgets, or sometimes other containers. Each container has its basic rule for how it lays out its children on the screen, possibly customized by requests from the children themselves.

Common container patterns include:

- put all children in a row, one after the next
- put all children in a column, one below the next
- arrange the children into a table or grid with some number of rows and columns

- anchor the children to the sides of the container, according to requests made by those children
- anchor the children to other children in the container, according to requests made by those children
- stack all children, one on top of the next
- and so on

In the sample activity above, the dominant pattern is a column, with things laid out from top to bottom. Some of those things are rows, with contents laid out left to right. However, as it turns out, the area with most of those widgets is scrollable.

Android supplies a handful of containers, designed to handle most common scenarios, including everything in the list above. You are also welcome to create your own custom containers, to implement business rules that are not directly supported by the existing containers.

Note that containers also have size, padding, and margins, just as widgets do.

The Absolute Positioning Anti-Pattern

You might wonder why all of these containers and such are necessary. After all, can't you just say that such-and-so widget goes at this pixel coordinate, and this other widget goes at that pixel coordinate, and so on?

Many developers have taken that approach — known as absolute positioning – over the years, to their eventual regret.

For example, many of you may have used Windows apps, back in the 1990's, where when you would resize the application window, the app would not really react all that much. You would expand the window, and the UI would not change, except to have big empty areas to the right and bottom of the window. This is because the developers simply said that such-and-so widget goes at this pixel coordinate, and this other widget goes at that pixel coordinate, **regardless of the actual window size**.

In modern Web development, you see this in the debate over fixed versus fluid Web design. The consensus seems to be that fluid designs are better, though frequently they are more difficult to set up. Fluid Web designs can better handle differing browser window sizes, whether those window sizes are because the user resized their browser window manually, or because those window sizes are dictated by the

screen resolution of the device viewing the Web page. Fixed Web designs — effectively saying that such-and-so element goes at such-and-so pixel coordinate and so on — tend to be easier to build but adapt more poorly to differing browser window sizes.

In mobile, particularly with Android, we have a wide range of possible screen resolutions, from QVGA (320x240) to beyond 1080p (1920x1080), and many values in between. Moreover, any device manufacturer is welcome to create a device with whatever resolution they so desire – there are no rules limiting manufacturers to certain resolutions. Hence, as developers, having the Android equivalent of fluid Web designs is critical, and the way you will accomplish that is by sensible use of containers, avoiding absolute positioning. The containers (and, to a lesser extent, the widgets) will determine how extra space is employed, as the screens get larger and larger.

The Theme of This Section: Themes

In Web development, we have had stylesheets for quite a while. Through such Cascading Style Sheets (CSS) files, we can stipulate various rules about how our Web pages should look. This includes:

- Establishing a default look for certain HTML tags by tag name (e.g., setting the font and size for all `<h1>` and `<h2>` elements)
- Establishing a look for specific HTML elements by class or ID (e.g., setting the width of a specific `<div>` to a certain number of CSS pixels)

In Android, the equivalent concepts can be found in styles and themes. Styles are a collection of values for properties (e.g., have a foreground color of red). These can be applied to specific widgets (e.g., this label should adopt this style), or they can be employed by "themes" that provide the default look for all sorts of widgets and other elements of our UI.

Of course, you do not have to declare any theme for your app. Android will give you a default look-and-feel without any specific theme. That look-and-feel has varied over the years, though, affecting the visual fundamentals of various Android widgets. These themes have names by which we refer to them: `Theme`, `Theme.Holo`, and `Theme.Material`.

In the Beginning, There Was "Theme", And It Was Meh

Way back in Android 1.0, the default theme was known simply as `Theme`. Technically, all themes inherit from `Theme`, much as how later CSS stylesheets effectively "inherit" the settings established by prior stylesheets.

The `Theme` UI had a particular look to it:

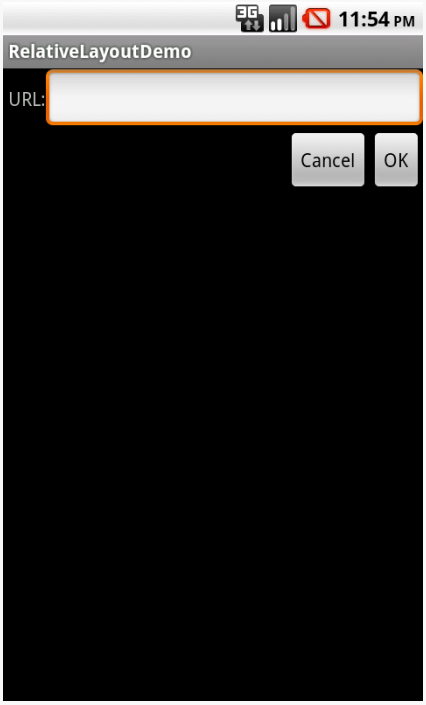

Figure 65: Labels, Fields, and Buttons in Theme

For example:

- At the top of the screen, we had a thin gray "title bar" with the name of our app
- The focused field (an `EditText` widget) had a bright orange outline, whereas normally it was a plain white rectangle
- The buttons ("OK" and "Cancel") were... well... buttons

Holo, There!

Android 3.0 (API Level 11) introduced a new default theme, `Theme.Holo`, with the so-called "holographic widget theme". This changed the look of our UI somewhat:

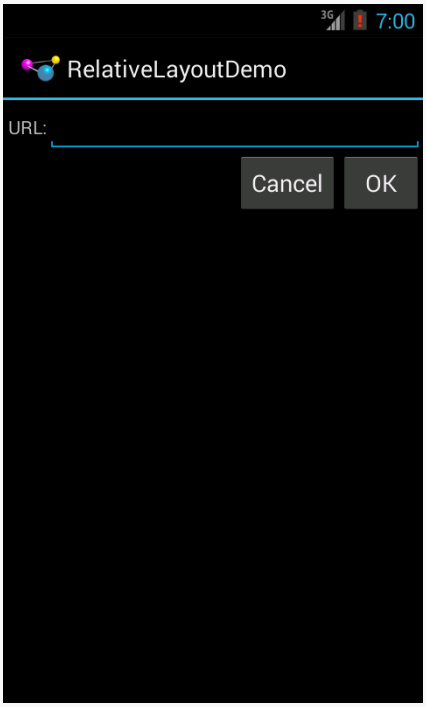

Figure 66: Labels, Fields, and Buttons in Theme.Holo

Now:

- At the top of the screen, we have an "action bar", containing our app's logo and name
- The focused field has a blue "underbracket", whereas normally it is gray
- The buttons are styled slightly differently, with a bigger font, alternative backgrounds, etc.

Considering the Material

Android 5.0 changed the default theme yet again, to `Theme.Material`:

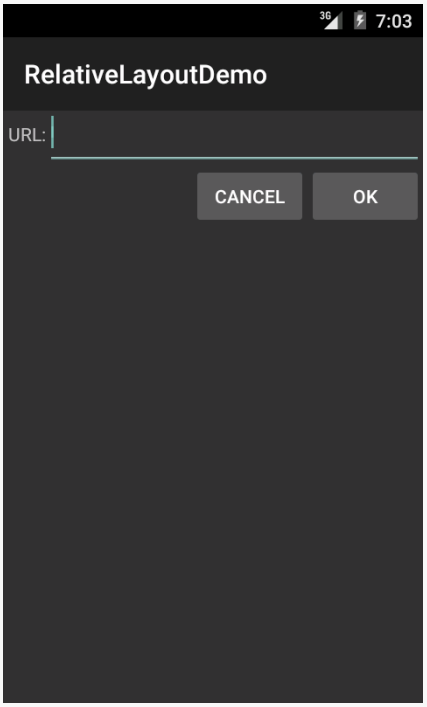

Figure 67: Labels, Fields, and Buttons in Theme.Material

Now:

- The action bar at the top of the screen no longer shows the app icon
- Our field is indicated by an underline, which is teal when focused or gray when unfocused
- The buttons are now forced into all-caps font, with a slightly smaller font size and subtly different background than we had with `Theme.Holo`

Doing More with Themes

Of course, we can do a lot more than just use these. There are other stock themes, with different characteristics. Furthermore, we can customize the themes, by defining our own (inheriting from a stock theme) and changing some of the properties (e.g., replacing the teal color with something else).

We will get much more into creating custom styles and themes later in the book.

However, we will see the effects of `Theme`, `Theme.Holo`, and `Theme.Material` on stock widgets in an upcoming chapter.

The Android User Interface

The project you created in an earlier tutorial was just the default files generated by the Android build tools — you did not write any Java code yourself. In this chapter, we will examine the basic Java code and resources that make up an Android activity.

The Activity

The Java source code that you maintain will be in a standard Java-style tree of directories based upon the Java package you chose when you created the project (e.g., `com.commonsware.android` results in `com/commonsware/android/`). Android Studio will have that source, by default, in `app/src/main/java/` off of the top-level project root.

If, in the new-project wizard, you elected to create an activity, you will have, in the innermost directory, a Java source file representing an activity class.

A very simple activity looks like:

```
package com.commonsware.empublite;

import android.app.Activity;
import android.os.Bundle;

public class EmPubLiteActivity extends Activity {

  @Override
  protected void onCreate(Bundle savedInstanceState) {
    super.onCreate(savedInstanceState);
    setContentView(R.layout.main);
  }
}
```

(from EmPubLite-AndroidStudio/T2-Project/EmPubLite/app/src/main/java/com/commonsware/empublite/EmPubLiteActivity.java)

Dissecting the Activity

Let's examine this Java code piece by piece:

```
package com.commonsware.empublite;

import android.app.Activity;
import android.os.Bundle;
```

(from EmPubLite-AndroidStudio/T2-Project/EmPubLite/app/src/main/java/com/commonsware/empublite/EmPubLiteActivity.java)

By default, the package declaration is the same as the one you used when creating the project. And, like any other Java project, you need to import any classes you reference. Most of the Android-specific classes are in the `android` package.

Remember that not every Java SE class is available to Android programs! Visit the Android class reference to see what is and is not available.

```
public class EmPubLiteActivity extends Activity {
```

(from EmPubLite-AndroidStudio/T2-Project/EmPubLite/app/src/main/java/com/commonsware/empublite/EmPubLiteActivity.java)

Activities are public classes, inheriting from the `android.app.Activity` base class (or, possibly, from some other class that itself inherits from `Activity`). You can have whatever data members you decide that you need, though the initial code has none.

```
  @Override
  protected void onCreate(Bundle savedInstanceState) {
    super.onCreate(savedInstanceState);
    setContentView(R.layout.main);
```

(from EmPubLite-AndroidStudio/T2-Project/EmPubLite/app/src/main/java/com/commonsware/empublite/EmPubLiteActivity.java)

The `onCreate()` method is invoked when the activity is started. We will discuss the `Bundle` parameter to `onCreate()` in a later chapter. For the moment, consider it an opaque handle that all activities receive upon creation.

The first thing you normally should do in `onCreate()` is chain upward to the superclass, so the stock Android activity initialization can be done. The only other statement in our stub project's `onCreate()` is a call to `setContentView()`. This is where we tell Android what the user interface is supposed to be for our activity.

This raises the question: what does `R.layout.main` mean? Where did this `R` come from?

To explain that, we need to start thinking about layout resources and how resources are referenced from within Java code.

Using XML-Based Layouts

As noted in the previous chapter, Android uses a series of widgets and containers to describe your typical user interface. These all inherit from an `android.view.View` base class, for things that can be rendered into a standard widget-based activity.

While it is technically possible to create and attach widgets and containers to our activity purely through Java code, the more common approach is to use an XML-based layout file. Dynamic instantiation of widgets is reserved for more complicated scenarios, where the widgets are not known at compile-time (e.g., populating a column of radio buttons based on data retrieved off the Internet).

With that in mind, it's time to break out the XML and learn how to lay out Android activity contents that way.

What Is an XML-Based Layout?

As the name suggests, an XML-based layout is a specification of its widgets' relationships to each other — and to containers — encoded in XML format. Specifically, Android considers XML-based layouts to be resources, and as such layout files are stored in the `res/layout/` directory inside your Android project (or, as we will see later, other layout resource sets, like `res/layout-land/` for layouts to use when the device is held in landscape). As has been noted elsewhere in this book, the initial location of `res/` is in `app/src/main/` for Android Studio.

Each XML file contains a tree of elements specifying a layout of widgets and containers that make up one `View`. The attributes of the XML elements are properties, describing how a widget should look or how a container should behave. For example, if a `Button` element has an attribute value of `android:textStyle = "bold"`, that means that the text appearing on the face of the button should be rendered in a boldface font style.

For example, here is a `res/layout/main.xml` file that could be used with the aforementioned activity:

```
<?xml version="1.0" encoding="utf-8"?>
<RelativeLayout android:id="@+id/main"
  xmlns:android="http://schemas.android.com/apk/res/android"
  xmlns:tools="http://schemas.android.com/tools"
  android:layout_width="match_parent"
  android:layout_height="match_parent"
  android:paddingBottom="@dimen/activity_vertical_margin"
  android:paddingLeft="@dimen/activity_horizontal_margin"
  android:paddingRight="@dimen/activity_horizontal_margin"
  android:paddingTop="@dimen/activity_vertical_margin"
  tools:context="com.commonsware.empublite.EmPubLiteActivity">

  <TextView
    android:layout_width="wrap_content"
    android:layout_height="wrap_content"
    android:text="Hello World!" />
</RelativeLayout>
```

(from EmPubLite-AndroidStudio/T2-Project/EmPubLite/app/src/main/res/layout/main.xml)

The class name of a widget or container — such as `RelativeLayout` or `TextView` – forms the name of the XML element. Since `TextView` is an Android-supplied widget, we can just use the bare class name. If you create your own widgets as subclasses of `android.view.View`, you would need to provide a full package declaration as well (e.g., `com.commonsware.android.MyWidget`).

The root element needs to declare the Android XML namespace (`xmlns:android="http://schemas.android.com/apk/res/android"`). All other elements will be children of the root and will inherit that namespace declaration.

The attributes are properties of the widget or container, describing what it should look and work like. For example, the `android:layout_width` and `android:layout_height` attributes on the `TextView` element make a request from the child (`TextView`) to its parent (a `RelativeLayout`) for what size the child should be.

We will get into details about these attributes, their possible values, and their uses, in upcoming chapters. Note that those attributes in the `tools` namespace (e.g., `tools:context`) are there solely to support the Android build tools, and do not affect the runtime execution of your project.

Android's SDK ships with a tool (`aapt`) which uses the layouts. This tool will be automatically invoked by your Android tool chain (e.g., Android Studio). Of particular importance to you as a developer is that `aapt` generates an `R.java` source

file, allowing you to access layouts and widgets within those layouts directly from your Java code. In other words, this is where that magic `R` value used in `setContentView()` comes from. We will discuss that a bit more later in this chapter.

XML Layouts and Your IDE

If you are using Android Studio, and you double-click on the `res/layout/main.xml` file in your project, you will not initially see that XML. Instead, you will be taken to the graphical layout editor:

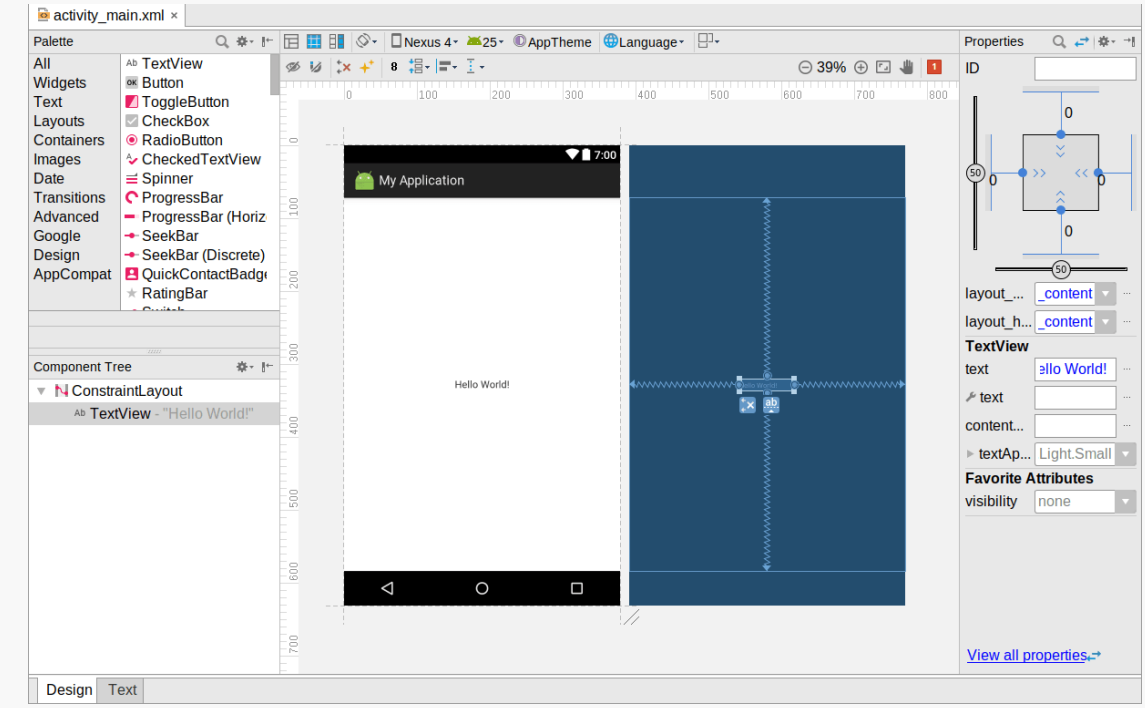

Figure 68: Android Studio Graphical Layout Editor

We will go into much more detail about using the graphical layout editor in an upcoming chapter, as we start to work more with specific widgets and containers.

Why Use XML-Based Layouts?

Almost everything you do using XML layout files can be achieved through Java code. For example, you could use `setText()` to have a button display a certain caption, instead of using a property in an XML layout. Since XML layouts are yet another file for you to keep track of, we need good reasons for using such files.

Perhaps the biggest reason is to assist in the creation of tools for view definition, such as the aforementioned graphical layout editors in Android Studio. Such GUI builders could, in principle, generate Java code instead of XML. The challenge is re-reading the definition in to support edits — that is far simpler if the data is in a structured format like XML than in a programming language. Moreover, keeping the generated bits separated out from hand-written code makes it less likely that somebody's custom-crafted source will get clobbered by accident when the generated bits get re-generated. XML forms a nice middle ground between something that is easy for tool-writers to use and easy for programmers to work with by hand as needed.

Also, XML as a GUI definition format is becoming more commonplace. Microsoft's XAML, Adobe's Flex, Google's GWT, and Mozilla's XUL all take a similar approach to that of Android: put layout details in an XML file and put programming smarts in source files (e.g., JavaScript for XUL). Many less-well-known GUI frameworks, such as ZK, also use XML for view definition. While "following the herd" is not necessarily the best policy, it does have the advantage of helping to ease the transition into Android from any other XML-centered view description language.

Using Layouts from Java

Given that you have painstakingly set up the widgets and containers for your view in an XML layout file named `main.xml` stored in `res/layout/`, all you need is one statement in your activity's `onCreate()` callback to use that layout, as we saw in our stub project's activity:

```
setContentView(R.layout.main);
```

Here, `R.layout.main` tells Android to load in the layout (`layout`) resource (`R`) named main.xml (`main`).

Basic Widgets

Every GUI toolkit has some basic widgets: fields, labels, buttons, etc. Android's toolkit is no different in scope, and the basic widgets will provide a good introduction as to how widgets work in Android activities. We will examine a number of these in this chapter.

Common Concepts

There are a few core features of widgets that we need to discuss at the outset, before we dive into details on specific types of widgets.

Widgets and Attributes

As mentioned in a previous chapter, widgets have attributes that describe how they should behave. In an XML layout file, these are literally XML attributes on the widget's element in the file. Usually, there are corresponding getter and setter methods for manipulating this attribute at runtime from your Java code.

If you visit the JavaDocs for a widget, such as the JavaDocs for `TextView`, you will see an "XML Attributes" table near the top. This lists all of the attributes defined uniquely on this class, and the "Inherited XML Attributes" table that follows lists all those that the widget inherits from superclasses, such as `View`. Of course, the JavaDocs also list the fields, constants, constructors, and public/protected methods that you can use on the widget itself.

This book does not attempt to explain each and every attribute on each and every widget. We will, however, cover the most popular widgets and the most commonly-used attributes on those widgets.

Referencing Widgets By ID

Many widgets and containers only need to appear in the XML layout file and do not need to be referenced in your Java code. For example, a static label (`TextView`) frequently only needs to be in the layout file to indicate where it should appear.

Anything you *do* want to use in your Java source, though, needs an `android:id`.

The convention is to use `@+id/...` as the `id` value (where the `...` represents your locally-unique name for the widget) for the first occurrence of a given `id` value in your layout file. The second and subsequent occurrences in the same layout file should drop the `+` sign.

Android provides a few special `android:id` values, of the form `@android:id/...` — we will see some of these in various chapters of this book.

To access our identified widgets, use `findViewById()`, passing it the numeric identifier of the widget in question. That numeric identifier was generated by Android in the `R` class as `R.id.something` (where `something` is the specific widget you are seeking).

This concept will become important as we try to attach listeners to our widgets (e.g., finding out when a checkbox is checked) or when we try referencing widgets from other widgets in a layout XML file (e.g., with `RelativeLayout`). All of this will be covered later in this chapter.

The Curious Case of the Cast

Most sample code that you will see for Android will show the results of the `findViewById()` call being cast to some other class:

```
TextView tv=(TextView)findViewById(R.id.name);
```

That is because for most of Android's existence, `findViewById()` returned a `View`, so we would need to down-cast that to a more appropriate class.

However, if you are using Android Studio 3.0+, with an app with a `compileSdkVersion` of 26 or higher, you will notice that you no longer need those casts. Any existing ones will show up in gray, with a tooltip indicating that the cast is unnecessary.

What happened is that Android 8.0 changed `findViewById()` to return `T`, using Java generics to automatically cast it to the data type you request in the assignment. Casts are a compile-time thing in Java — they do not appear in compiled code and have no effects at runtime. As a result, code that skips the casts works perfectly fine on older devices as well.

Size

Most of the time, we need to tell Android how big we want our widgets to be. Occasionally, this will be handled for us — we will see an example of that with `TableLayout` in an upcoming chapter. But generally we need to provide this information ourselves.

To do that, you need to supply `android:layout_width` and `android:layout_height` attributes on your widgets in the XML layout file. These attributes' values have three flavors:

1. You can provide a specific dimension, such as `125dip` to indicate the widget should take up exactly a certain size (here, 125 density-independent pixels)
2. You can provide `wrap_content`, which means the widget should take up as much room as its contents require (e.g., a `TextView` label widget's content is the text to be displayed)
3. You can provide `match_parent`, which means the widget should fill up all remaining available space in its enclosing container

The latter two flavors are the most common, as they are independent of screen size, allowing Android to adjust your view to fit the available space.

Note that you will also see `fill_parent`. This is an older synonym for `match_parent`. `match_parent` is the recommended value going forward, but `fill_parent` will certainly work.

This chapter focuses on individual widgets. Size becomes much more important when we start combining multiple widgets on the screen at once, and so we will be spending more time on sizing scenarios in later chapters.

The `layout_` prefix on these attributes means that these attributes represent requests by the widget to its enclosing container. Whether those requests will be truly honored will depend a bit on what other widgets there are in the container and what *their* requests are.

Introducing the Graphical Layout Editor

If you open a layout resource in Android Studio, by default you will see the graphical layout editor:

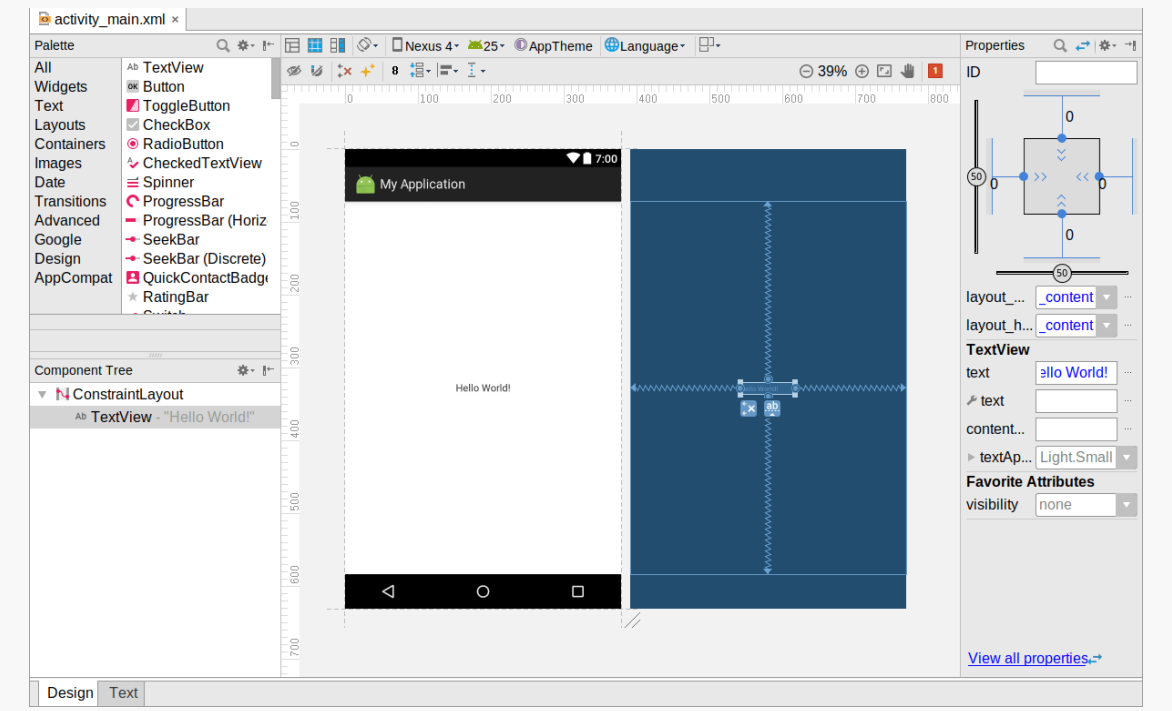

Figure 69: Android Studio Graphical Layout Editor

This offers a drag-and-drop means of defining the contents of that layout resource.

Android IDEs have had drag-and-drop GUI building capability for several years, dating back to when Eclipse was the official IDE. However, Android Studio 2.2 made some significant changes in the way the drag-and-drop GUI builder looks and works, and later updates have changed it further. This book covers the current look-and-feel, but older blog posts, Stack Overflow answers, and similar resources may refer to aspects of previous GUI builders.

With all that in mind, let's look at the different pieces of the graphical layout editor.

Palette

The upper-left side of the graphical layout editor is the Palette tool:

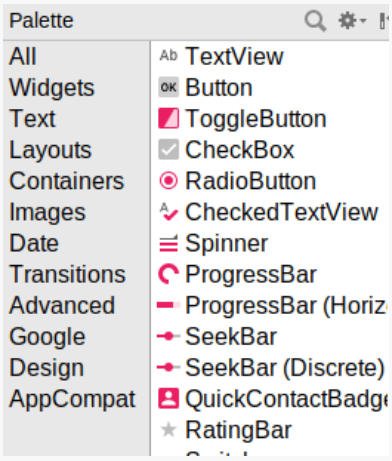

Figure 70: Palette Tool

This lists all sorts of widgets and containers that you can drag and drop. They are divided into categories ("Widgets", "Text", "Layouts", etc.) with many options in each. A few are not strictly widgets or containers but rather other sorts of XML elements that you can have in a layout resource (e.g., `<fragment>`, `<requestFocus>`).

As we cover how to use the graphical layout editor, we will see how to create and configure several of these widgets, containers, and other items.

Preview

The main central area of the graphical layout editor consists of two perspectives on your layout resource contents. The one on the left is a preview of what your UI should resemble, if this layout were used for the UI of an activity:

Figure 71: UI Preview

This pours your layout resource contents into a preview frame that has aspects of a regular Android device, such as the navigation bar at the bottom and the status bar at the top.

If you drag items out of the Palette and drop them into the preview area, they will be added to your layout resource.

Blueprint

To the right of the preview area is the blueprint view. This also visually depicts your layout resource. However, rather than showing you a preview of what your UI might look like, it visually represents what widget and container classes you are using. And, for some types of containers, it will show some of the sizing and positioning rules that you are using for children of that container:

Figure 72: Blueprint

For a trivial layout resource, the blueprint view does not show you much. It will become more useful with more complex layout resources. In particular, it is very useful when you have designated some widgets or containers as being invisible, as they will show up in the blueprint but not in the preview:

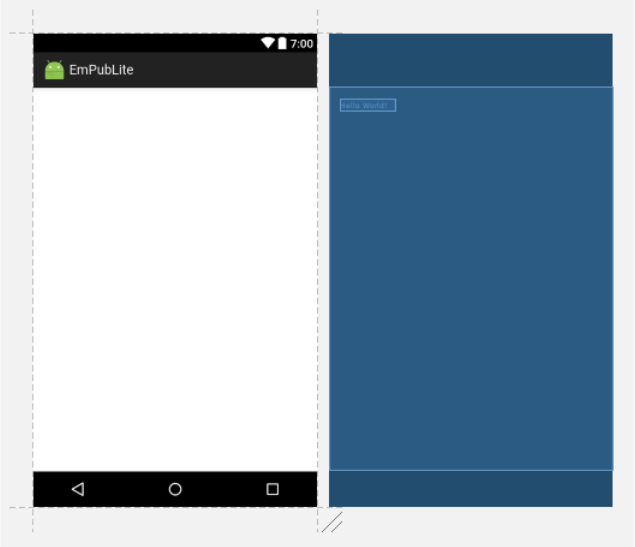

Figure 73: Layout Resource with Invisible TextView

Preview Toolbar

Above the preview and blueprint is a bi-level toolbar that allows you to configure various aspects of the preview and blueprint appearance and behavior.

Upper Toolbar Level

From left to right, the upper level of the toolbar contains:

- A drop-down to toggle whether you see the preview, the blueprint, or both
- A toggle to control whether you are seeing the layout as applied to portrait or landscape perspectives
- A drop-down to choose what device size and resolution should be used for the preview, culled from your emulator images and the available device definitions
- A drop-down to choose what API level should be used for the simulated UI of the preview
- A button to choose what theme to use for presenting the UI of the preview
- A button to choose what language to use for determining which of your string resources gets used in the preview

Figure 74: Preview Toolbar, Top Level

A couple of those — particularly the theme selector — pertain to topics that we will explore later in the book.

Lower Toolbar Level

On the right side of the lower toolbar level are:

- Zoom controls
- A button to reset the zoom to fill the area available for the preview and/or blueprint
- A button to enable “Pan and Zoom” mode (more on this shortly)
- An “info” icon indicating if there are any warnings or errors associated with your layout resource

Figure 75: Preview Toolbar, Bottom Level, Right Side

The left side of the bottom level of the preview toolbar will change, based upon the selected widget or container, offering options for you to be able to make simple changes to whatever is selected. We will see examples of this over the next few chapters

Pan and Zoom Mode

The "Pan and Zoom" mode allows you to navigate a zoomed-in version of your preview and/or blueprint. While the main views will be zoomed in, tapping the "Pan and Zoom" toolbar button opens up a floating window showing the entire preview and/or blueprint, with a red box indicating what portion of that you are seeing in the main views:

Figure 76: Preview and Blueprint, with Pan and Zoom Enabled

You can drag the red frame around the floating window to change what portion of the entire zoomed-in view you can see in the main view.

Component Tree

Towards the bottom-left corner is the component tree:

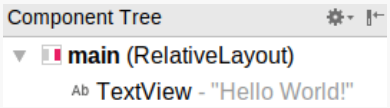

Figure 77: Component Tree

This gives you a full tree of all of the widgets and containers inside of this layout resource. It corresponds to the tree of XML elements in the layout resource itself.

Clicking on any item in the component tree highlights it in both the preview and blueprint views, plus it switches to that widget or container for the attributes pane.

Attributes

When a widget or container is selected — whether via the component tree, clicking on it in the preview, or clicking on it in the blueprint – the Attributes pane on the right will allow you to manipulate how that widget or container looks and behaves.

By default, it will bring up a condensed roster of the most important attributes:

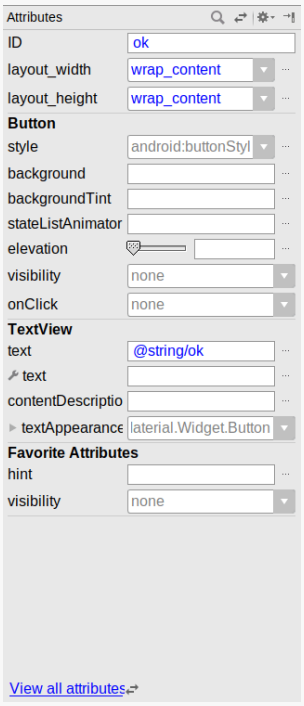

Figure 78: Attributes Pane, Showing Condensed Roster

Clicking the “View all attributes” link, or the opposing-arrows toolbar button, switches to a list of all attributes:

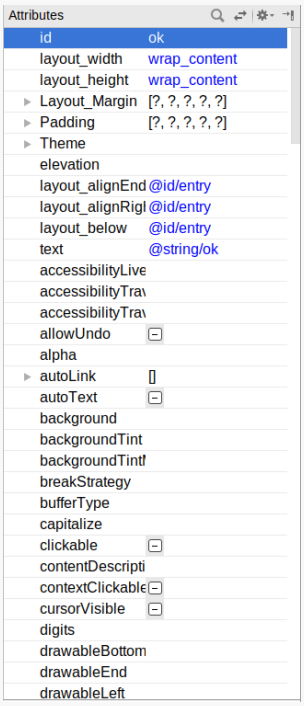

Figure 79: Attributes Pane, Showing Full Roster

You can also click the magnifying glass icon in the toolbar of this pane to search for available attributes by name:

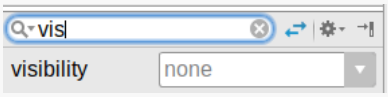

Figure 80: Attributes Pane, Showing Search Results

We will see what many of these attributes are and how to work with them over the course of the next few chapters.

For the attributes in the full roster, you can click the star icon on the left to mark them as “favorites”:

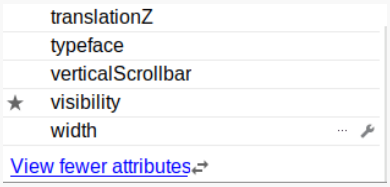

Figure 81: Attributes Pane, Showing One Favorite Attribute

Those favorite attributes show up in the condensed roster, in the section labeled "Favorite Attributes".

Text Tab

Towards the bottom of the graphical layout tool, you will see that it contains two sub-tabs. One, "Design", encompasses everything described above. The other, "Text", allows you to edit the raw XML that is the actual content of the layout resource:

Figure 82: Text Sub-Tab in Layout Editor

By default, the entire area is devoted to the text editor. However, when the Text sub-tab is active, a "Preview" tool will appear docked on the right side of the Android Studio window. Clicking that will display the preview from the Design sub-tab:

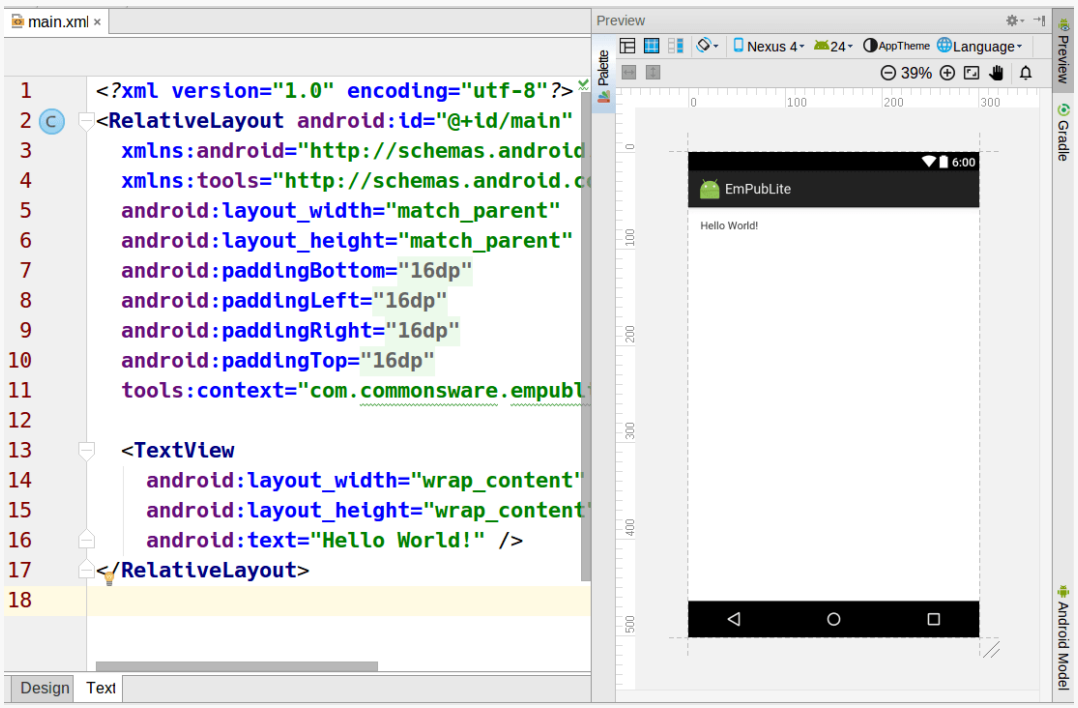

Figure 83: Text Sub-Tab with Preview

Clicking on items in the preview will highlight the corresponding XML element in the text editor.

And Now, Some Notes About the Book's Sample Projects

This book profiles hundreds of sample apps, demonstrating everything from how to display text on the screen to how to scan NFC tags or work with the clipboard.

These sample apps are housed in a Git repository on GitHub. They are all open source, and the *vast* majority are licensed under the Apache Software License 2.0, in case you copy any of the code.

The Git repo uses tags that match the book version numbers (e.g., the `v8.8` tag is for Version 8.8 of the book). Hence, to get the source code that matches your book version, you can:

- Clone the repo (e.g., `git clone https://github.com/commonsguy/cw-omnibus.git`) and then checkout a particular tag; or

- Download the ZIP archive associated with a particular book version

For those projects that you wish to examine in Android Studio, you can use File > New > Import Project to import the project. However, you have to do this on a project-by-project basis, importing each project directory as needed. Roughly speaking, any directory that has `settings.gradle` in it is a project directory, particularly with respect to this book's samples.

Starting with the next section, the book will be displaying code from these sample projects. Links will point you to a particular sample project or to a specific file in that project, such as a layout resource or Java source file. Those links go to the GitHub repository, but you can use that information to help you identify where the corresponding file is on your development machine, if you elected to download the code.

Assigning Labels

The simplest widget is the label, referred to in Android as a `TextView`. Like in most GUI toolkits, labels are bits of text not editable directly by users. Typically, they are used to identify adjacent widgets (e.g., a "Name:" label before a field where one fills in a name).

In Java, you can create a label by creating a `TextView` instance. More commonly, though, you will create labels in XML layout files by adding a `TextView` element to the layout, with an `android:text` attribute to set the value of the label itself. If you need to swap labels based on certain criteria, such as internationalization, you may wish to use a string resource reference in `android:text` instead (e.g., `@string/label`).

For example, in our last tutorial, we still are using the automatically-generated `res/layout/main.xml` file, containing, among other things, a `TextView`:

```
<?xml version="1.0" encoding="utf-8"?>
<RelativeLayout android:id="@+id/main"
  xmlns:android="http://schemas.android.com/apk/res/android"
  xmlns:tools="http://schemas.android.com/tools"
  android:layout_width="match_parent"
  android:layout_height="match_parent"
  android:paddingBottom="@dimen/activity_vertical_margin"
  android:paddingLeft="@dimen/activity_horizontal_margin"
  android:paddingRight="@dimen/activity_horizontal_margin"
  android:paddingTop="@dimen/activity_vertical_margin"
```

```
  tools:context="com.commonsware.empublite.EmPubLiteActivity">

  <TextView
    android:layout_width="wrap_content"
    android:layout_height="wrap_content"
    android:text="Hello World!" />

</RelativeLayout>
```

(from EmPubLite-AndroidStudio/T4-Resources/EmPubLite/app/src/main/res/layout/main.xml)

Android Studio Graphical Layout Editor

The `TextView` widget is available in the "Widgets" category of the Palette in the Android Studio graphical layout editor:

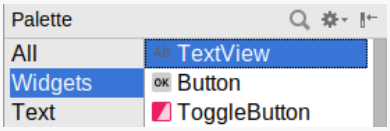

Figure 84: Palette, "Plain TextView" in Widgets Category

You can drag that `TextView` from the palette into a layout file in the main editing area to add the widget to the layout. Or, drag it over the top of some container you see in the Component Tree pane of the editor to add it as a child of that specific container.

Clicking on the new `TextView` will set up the Attributes pane with the various attributes of the widget, ready for you to change as needed.

Editing the Text

The "Text" attribute will allow you to choose or define a string resource to serve as the text to be displayed:

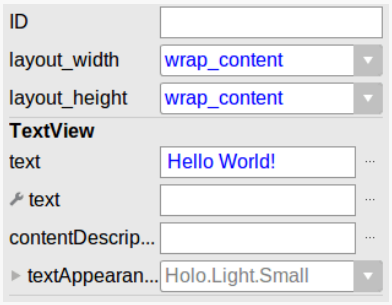

Figure 85: Attributes Pane, Showing TextView "text" Attribute

The "text" with a wrench icon allows you to provide a separate piece of text that will show up in the preview, but not be used by your app at runtime.

You can either type a literal string right in the Attributes pane row, or you can click the "..." button to the right of the field to pick a string resource:

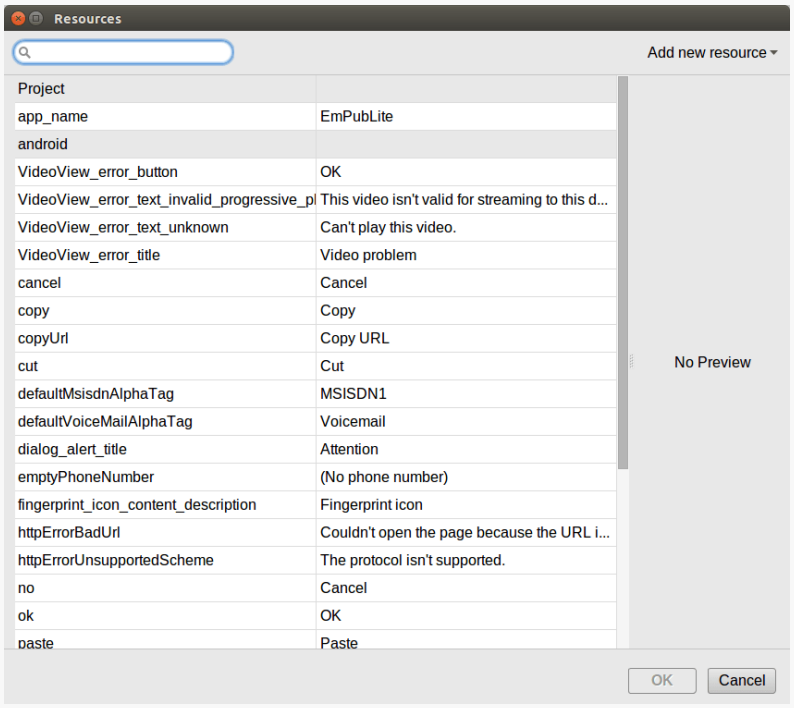

Figure 86: String Resources Dialog

You can highlight one of those resources and click "OK" to use it. Or, towards the upper-right of that dialog, there is an "Add new resource" drop-down. When viewing string resources, that drop-down will contain a single command: "New string

Value...". Choosing it will allow you to define a new string resource via another dialog:

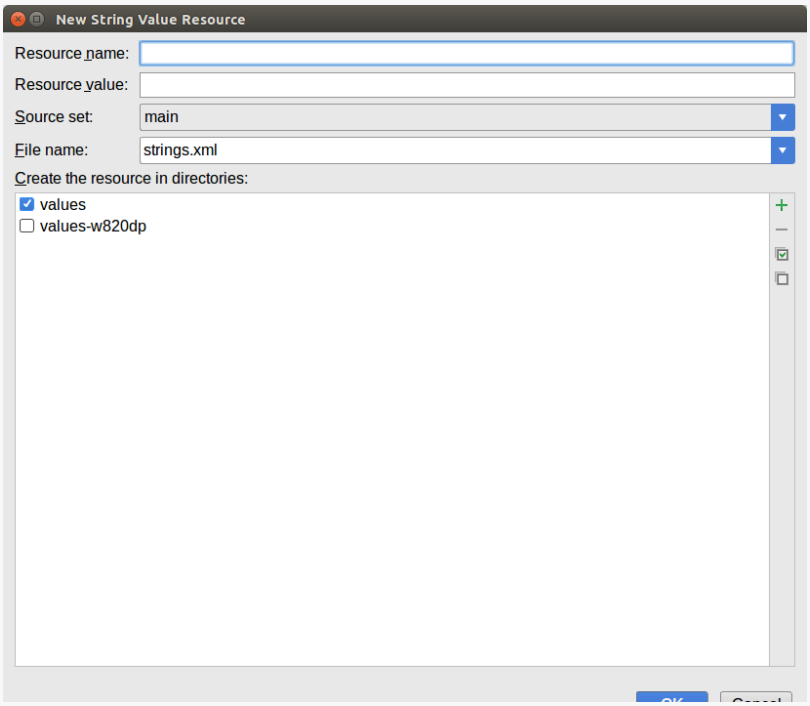

Figure 87: New String Resource Dialog

You can give your new string resource a name, the actual text of the string itself, the filename in which the string resource should reside (`strings.xml` by default), and which `values/` directory the string should go into (`values` by default). You will also choose the "source set" — for now, that will just be `main`. Once you accept the dialog, your new string resource will be applied to your `TextView`.

Editing the ID

The "id" attribute will allow you to change the `android:id` value of the widget:

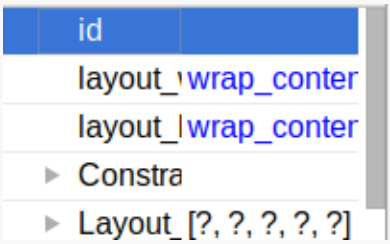

Figure 88: Attributes Pane, with TextView "id" Attribute Selected

The value you fill in here is what goes after the `@+id/` portion (e.g., `textView2`).

Notable TextView Attributes

`TextView` has numerous other attributes of relevance for labels, such as:

1. `android:typeface` to set the typeface to use for the label (e.g., `monospace`)
2. `android:textStyle` to indicate that the typeface should be made bold (`bold`), italic (`italic`), or bold and italic (`bold_italic`)
3. `android:textColor` to set the color of the label's text, in RGB hex format (e.g., `#FF0000` for red) or ARGB hex format (e.g., `#88FF0000` for a translucent red)

These attributes, like most others, can be modified through the Attributes pane.

For example, in the `Basic/Label` sample project, you will find the following layout file:

```
<?xml version="1.0" encoding="utf-8"?>
<TextView xmlns:android="http://schemas.android.com/apk/res/android"
  android:layout_width="match_parent"
  android:layout_height="wrap_content"
  android:text="@string/profound"
  />
```

(from Basic/Label/app/src/main/res/layout/main.xml)

Just that layout alone, with the stub Java source provided to your app, along with appropriate string resources, gives you:

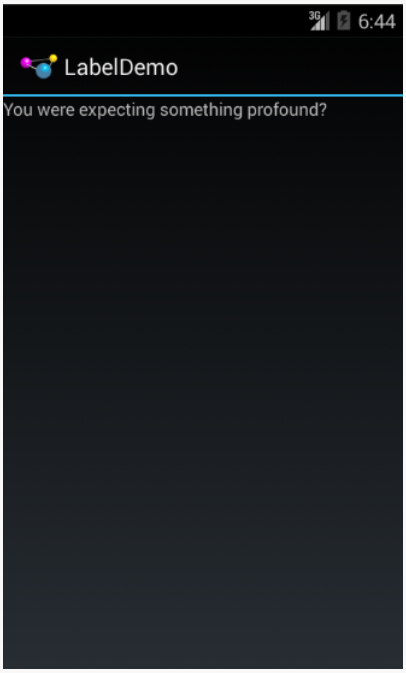

Figure 89: The LabelDemo Sample Application

A Commanding Button

Android has a `Button` widget, which is your classic push-button "click me and something cool will happen" widget. As it turns out, `Button` is a subclass of `TextView`, so everything discussed in the preceding section in terms of formatting the face of the button still holds.

For example, in the `Basic/Button` sample project, you will find the following layout file:

```
<?xml version="1.0" encoding="utf-8"?>
<LinearLayout xmlns:android="http://schemas.android.com/apk/res/android"
  android:layout_width="match_parent"
  android:layout_height="match_parent"
  android:orientation="vertical">

  <Button
    android:id="@+id/button1"
    android:layout_width="wrap_content"
    android:layout_height="wrap_content"
    android:text="@string/button"/>
```

```
</LinearLayout>
```

(from Basic/Button/app/src/main/res/layout/main.xml)

Just that layout alone, with the stub Java source provided to your app, along with appropriate string resources, gives you:

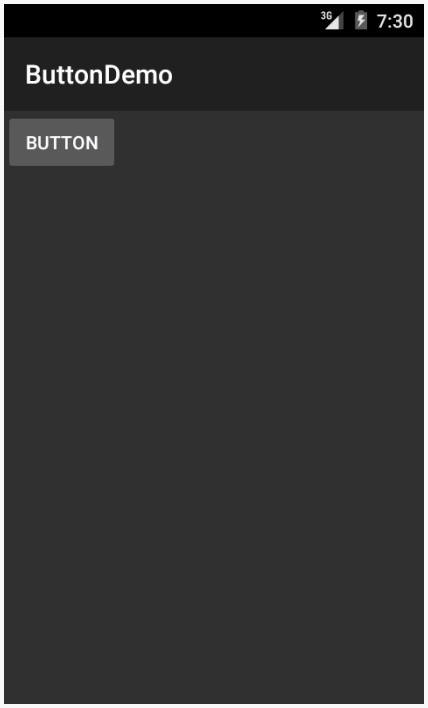

Figure 90: Button Widget

Android Studio Graphical Layout Editor

As with the `TextView` widget, the `Button` widget is available in the "Widgets" portion of the Palette in the Android Studio graphical layout editor:

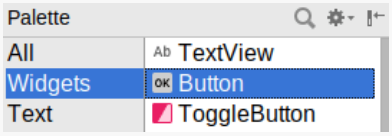

Figure 91: Widgets Palette, Button Shown Highlighted

You can drag that `Button` from the palette into a layout file in the main editing area to add the widget to the layout. The Attributes pane will then let you adjust the

various attributes of this `Button`. Since `Button` inherits from `TextView`, most of the options are the same (e.g., "Text").

Tracking Button Clicks

Buttons are command widgets — when the user presses a button, they expect something to happen.

To define what happens when you click a `Button`, you can:

1. Define some method on your `Activity` that holds the button that takes a single `View` parameter, has a `void` return value, and is `public`
2. In your layout XML, on the `Button` element, include the `android:onClick` attribute with the name of the method you defined in the previous step

For example, we might have a method on our `Activity` that looks like:

```
public void someMethod(View theButton) {
  // do something useful here
}
```

Then, we could use this XML declaration for the `Button` itself, including `android:onClick`:

```
<Button
  android:onClick="someMethod"
  ...
/>
```

This is enough for Android to "wire together" the `Button` with the click handler. When the user clicks the button, `someMethod()` will be called.

Another approach is to skip `android:onClick`, instead calling `setOnClickListener()` on the `Button` object in Java code. When a `Button` is used directly by an activity, this is not typically used — `android:onClick` is a bit cleaner. However, when we start to talk about fragments, you will see that `android:onClick` does not work that well with fragments, and so we will use `setOnClickListener()` at that point.

Fleeting Images

Android has two widgets to help you embed images in your activities: `ImageView` and `ImageButton`. As the names suggest, they are image-based analogues to `TextView` and `Button`, respectively.

Each widget takes an `android:src` attribute (in an XML layout) to specify what picture to use. These usually reference a drawable resource (e.g., `@drawable/icon`).

`ImageButton`, a subclass of `ImageView`, mixes in the standard `Button` behaviors, for responding to clicks and whatnot.

For example, take a peek at the `main.xml` layout from the `Basic/ImageView` sample project:

```
<?xml version="1.0" encoding="utf-8"?>
<ImageView xmlns:android="http://schemas.android.com/apk/res/android"
  android:id="@+id/icon"
  android:layout_width="match_parent"
  android:layout_height="match_parent"
  android:adjustViewBounds="true"
  android:src="@drawable/molecule"/>
```

(from Basic/ImageView/app/src/main/res/layout/main.xml)

The result, just using the code-generated activity, is simply the image:

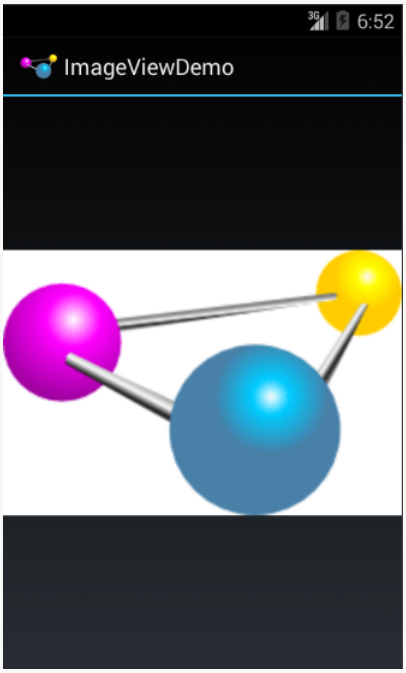

Figure 92: The ImageViewDemo sample application

Android Studio Graphical Layout Editor

The `ImageView` widget can be found in the "Images & Media" portion of the Palette in the Android Studio graphical layout editor:

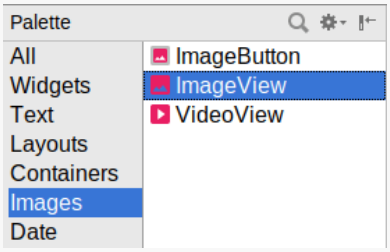

Figure 93: Widgets Palette, ImageView Shown Highlighted

`ImageButton` appears alongside `ImageView` in that tool palette.

When you drag one of these into the preview or blueprint, you are immediately greeted by a dialog to choose a drawable resource or color to use for the image:

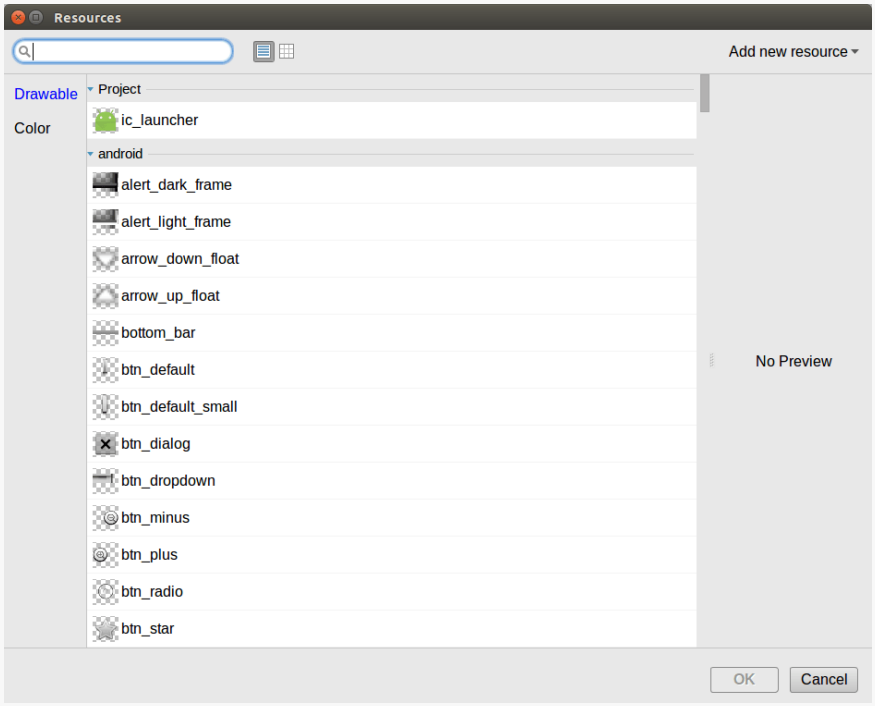

Figure 94: Image Resource Dialog

Unfortunately, you have no choice but to choose one of these, as due to a bug, if you click Cancel to exit the dialog, it also abandons the entire drag-and-drop operation.

You can drag these into a layout file, then use the Attributes pane to set their attributes. Like all widgets, you will have an "id" option to set the `android:id` value for the widget. Two others of importance, though, are more unique to `ImageView` and `ImageButton`:

- "src" allows you to choose a drawable resource to use as the image to be displayed, which will be filled in by whatever you chose in the resource dialog
- "contentDescription" provides the text that will be used to describe the image to users that have accessibility services enabled (e.g., TalkBack), such as visually impaired users
- "scaleType" opens a drop-down menu where you can choose how the image is to be scaled:

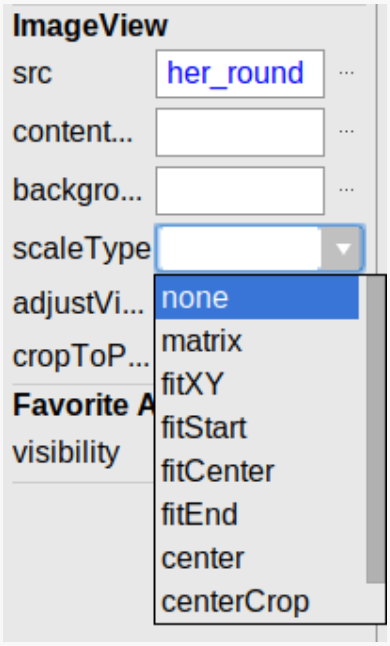

Figure 95: Scale Types in Android Studio Attributes Pane

We will examine those scale types more in the next section.

Scaling Images

It is possible, perhaps even probable, that our `ImageView` size will not exactly match the size of the images that we are trying to display. `ImageView` supports a variety of "scale types" that indicate how Android should try to deal with the discrepancy between the size/aspect ratio of the image and the size/aspect ratio of the `ImageView` itself.

These values can be seen in the JavaDocs in the `ImageView.ScaleType` class. The default (`fitCenter`) simply scales up the image to best fit the available space.

Of note, a choice of "center" will center the image in the available space but will not scale up the image:

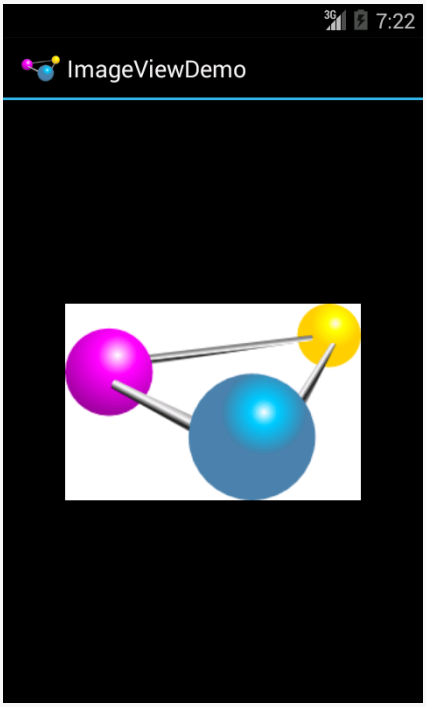

Figure 96: The ImageViewDemo Sample, Set to center

A choice of `centerCrop` will scale the image so that its shortest dimension fills the available space and crops the rest:

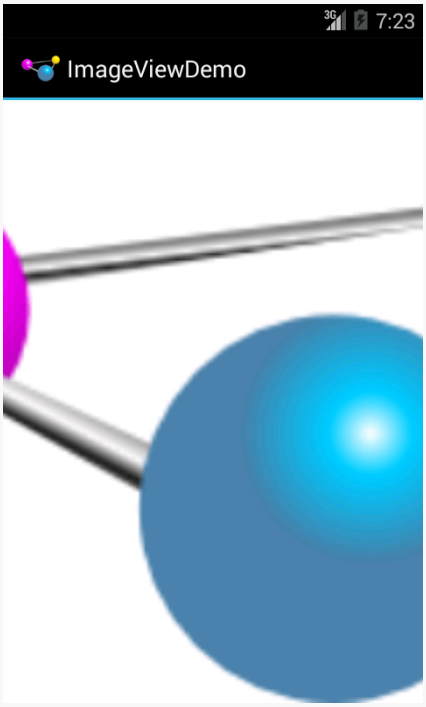

Figure 97: The ImageViewDemo Sample, Set to centerCrop

A choice of `fitXY` will scale the image to fill the space, ignoring the aspect ratio:

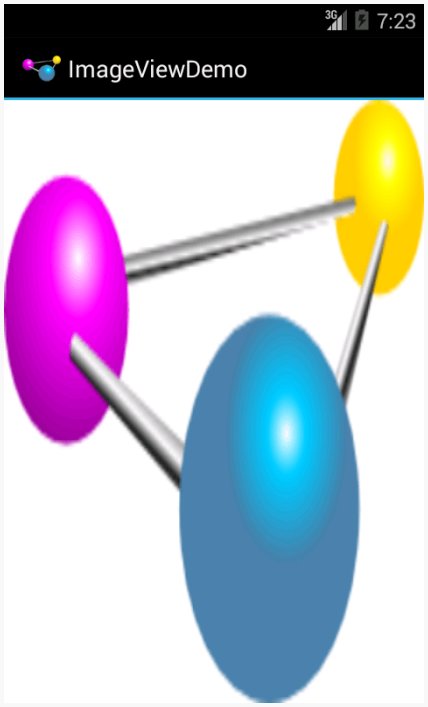

Figure 98: The ImageViewDemo Sample, Set to fitXY

Fields of Green. Or Other Colors.

Along with buttons and labels, fields are the third "anchor" of most GUI toolkits. In Android, they are implemented via the `EditText` widget, which is a subclass of the `TextView` used for labels.

Along with the standard `TextView` attributes (e.g., `android:textStyle`), `EditText` has others that will be useful for you in constructing fields, notably `android:inputType`, to describe what sort of input your `EditText` expects (numbers? email addresses? phone numbers?). A thorough explanation of `android:inputType` and its interaction with input method editors (a.k.a., "soft keyboards") will be discussed in an upcoming chapter.

For example, from the `Basic/Field` sample project, here is an XML layout file showing an `EditText`:

```
<?xml version="1.0" encoding="utf-8"?>
<EditText xmlns:android="http://schemas.android.com/apk/res/android"
  android:id="@+id/field"
  android:layout_width="match_parent"
```

```
android:layout_height="match_parent"
android:inputType="textMultiLine"
android:text="@string/license"
/>
```

(from Basic/Field/app/src/main/res/layout/main.xml)

Note that we have `android:inputType="textMultiLine"`, so users will be able to enter in several lines of text. We also have defined the initial text to be the value of a `license` string resource.

The result, once built and installed into the emulator, is:

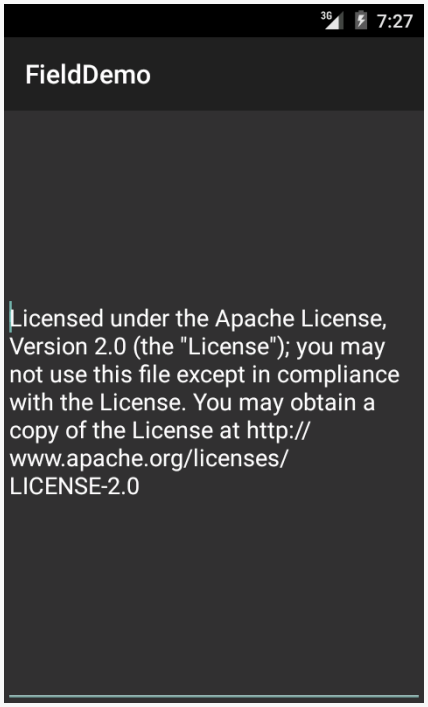

Figure 99: FieldDemo, in Theme.Material

Android Studio Graphical Layout Editor

The Android Studio Graphical Layout's Palette has a whole section dedicated primarily to `EditText` widgets, named "Text Fields (EditText)":

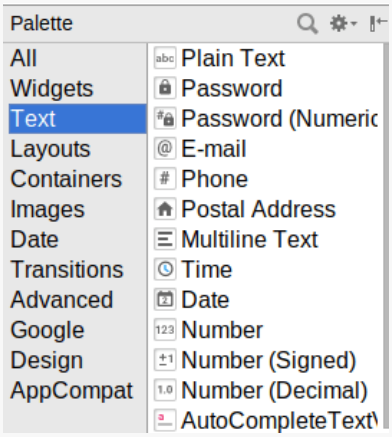

Figure 100: Text Fields Palette

The first entry is a general-purpose `EditText`. The rest come pre-configured for various scenarios, such as a password.

You can drag any of these into your layout, then use the Attributes pane to configure relevant attributes. The "Id" and "Text" attributes are the same as found on `TextView`, as are many other attributes, inherited from `TextView`.

Notable EditText Attributes

The "Hint" item in the Attributes pane allows you to set a "hint" for this `EditText`. The "hint" text will be shown in light gray in the `EditText` widget when the user has not entered anything yet. Once the user starts typing into the `EditText`, the "hint" vanishes. This might allow you to save on screen space, replacing a separate label `TextView`.

The "Input Type" item in the Attributes pane allows you to describe what sort of input you are expecting to receive in this `EditText`, lining up with many of the types of fields you can drag from the Palette into the layout:

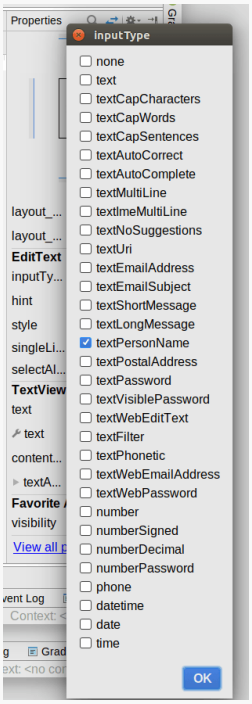

Figure 101: Android Studio's Text Fields InputType List

The `inputType` attribute will be covered in greater detail in an upcoming chapter.

More Common Concepts

All widgets, including the ones shown above, extend `View`. The `View` base class gives all widgets an array of useful attributes and methods beyond those already described.

Padding

Widgets have a minimum size, one that may be influenced by what is inside of them. So, for example, a `Button` will expand to accommodate the size of its caption. You can control this size using padding. Adding padding will increase the space between the contents (e.g., the caption of a `Button`) and the edges of the widget.

Padding can be set once in XML for all four sides (`android:padding`) or on a per-side basis (`android:paddingLeft`, etc.). Padding can also be set in Java via the `setPadding()` method. On Android 8.0+, there is also `android:paddingHorizontal` and `android:paddingVertical`, to set the padding on both sides of a single axis.

The value of any of these is a dimension — a combination of a unit of measure and a count. So, `10dip` is 10 density-independent pixels, `2mm` is 2 millimeters, etc.

Margins

By default, widgets are tightly packed, one next to the other. You can control this via the use of margins, a concept that is reminiscent of the padding described previously.

The difference between padding and margins comes in terms of the background. For widgets with a transparent background — like the default look of a `TextView` — padding and margins have similar visual effect, increasing the space between the widget and adjacent widgets. However, for widgets with a non-transparent background — like a `Button` — padding is considered inside the background while margins are outside. In other words, adding padding will increase the space between the contents (e.g., the caption of a `Button`) and the edges, while adding margin increases the empty space between the edges and adjacent widgets.

Margins can be set in XML, either on a per-side basis (e.g., `android:layout_marginTop`) or on all sides via `android:layout_margin`. Once again, the value of any of these is a dimension — a combination of a unit of measure and a count, such as `5dp` for 5 density-independent pixels. On Android 8.0+, there is also `android:layout_marginHorizontal` and `android:layout_marginVertical`, to set the margin on both sides of a single axis.

Colors

There are two types of color attributes in Android widgets. Some, like `android:background`, take a single color (or a drawable to serve as the background). Others, like `android:textColor` on `TextView` (and subclasses) can take a `ColorStateList`, including via the Java setter (in this case, `setTextColor()`).

A `ColorStateList` allows you to specify different colors for different conditions. For example, when you get to selection widgets in an upcoming chapter, you will see how a `TextView` has a different text color when it is the selected item in a list compared to when it is in the list but not selected. This is handled via the default `ColorStateList` associated with `TextView`.

If you wish to change the color of a `TextView` widget in Java code, you have two main choices:

- Use `ColorStateList.valueOf()`, which returns a `ColorStateList` in which all states are considered to have the same color, which you supply as the parameter to the `valueOf()` method. This is the Java equivalent of the `android:textColor` approach, to make the `TextView` always be a specific color regardless of circumstances.
- Create a `ColorStateList` with different values for different states, either via the constructor or via an XML drawable resource. This will be covered much later in the book.

Other Useful Attributes

Some additional attributes on `View` most likely to be used include:

1. `android:visibility`, which controls whether the widget is initially visible
2. `android:nextFocusDown`, `android:nextFocusLeft`, `android:nextFocusRight`, and `android:nextFocusUp`, which control the focus order if the user uses the D-pad, trackball, or similar pointing device
3. `android:contentDescription`, which is roughly equivalent to the `alt` attribute on an HTML `<img>` tag, and is used by accessibility tools to help people who cannot see the screen navigate the application — this is very important for widgets like `ImageView`

We will see more about the focus attributes and `android:contentDescription` in the chapter on focus management and accessibility, later in this book.

Useful Methods

You can toggle whether or not a widget is enabled via `setEnabled()` and see if it is enabled via `isEnabled()`. One common use pattern for this is to disable some widgets based on a `CheckBox` or `RadioButton` checked state. We will explore `CheckBox`, `RadioButton`, and similar sorts of widgets a bit later in the book.

You can give a widget focus via `requestFocus()` and see if it is focused via `isFocused()`. You might use this in concert with disabling widgets as mentioned above, to ensure the proper widget has the focus once your disabling operation is complete.

To help navigate the tree of widgets and containers that make up an activity's overall view, you can use:

1. `getParent()` to find the parent widget or container

2. `findViewById()` to find a child widget with a certain ID
3. `getRootView()` to get the root of the tree (e.g., what you provided to the activity via `setContentView()`)

Visit the Trails!

You can learn more about Android's input method framework — what you might think of as soft keyboards — in a later chapter.

Another chapter in the trails covers the use of fonts, to tailor your `TextView` widgets (and those that inherit from them, like `Button`).

Yet another chapter in the trails covers rich text formatting, both for presenting formatted text in a `TextView` (e.g., inline **boldface**) and for collecting formatted text from the user via a customized `EditText`.

Debugging Your App

Now that we are starting to manipulate layouts and Java code more significantly, the odds increase that we are going to somehow do it wrong, and our app will crash.

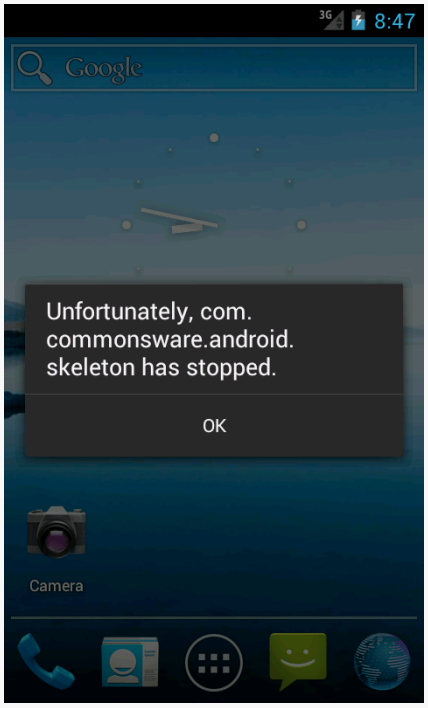

Figure 102: A Crash Dialog on Android 4.0.3

In this chapter, we will cover a few tips on how to debug these sorts of issues.

Get Thee To a Stack Trace

If you see one of those "Force Close" or "Has Stopped" dialogs, the first thing you will want to do is examine the Java stack trace that is associated with this crash. These are logged to a facility known as Logcat, on your device or emulator.

To view Logcat, you have three choices:

1. Use the `adb logcat` command at the command line (or something that uses `adb logcat`, such as various colorizing scripts available online)
2. Use the Logcat tab in the standalone Android Device Monitor utility (run `monitor` from the command line)
3. Use the Logcat view

There are also Logcat apps on the Play Store, such as aLogcat, that will display the contents of Logcat. However, for security and privacy reasons, on Android 4.1 and higher devices, such apps will only be able to show you *their* Logcat entries, not those from the system, your app, or anyone else. Hence, for development purposes, it is better to use one of the other alternatives outlined above.

Logcat in Android Studio

The Logcat view is available at any time, from pretty much anywhere in Android Studio, by means of clicking on the Android tool window entry, usually docked at the bottom of your IDE window:

Figure 103: Minimized Tool Windows in Android Studio, Showing Logcat Tool

Tapping on that will bring up some Android-specific logs in an "Android DDMS" tool window, with a tab for "Devices | logcat":

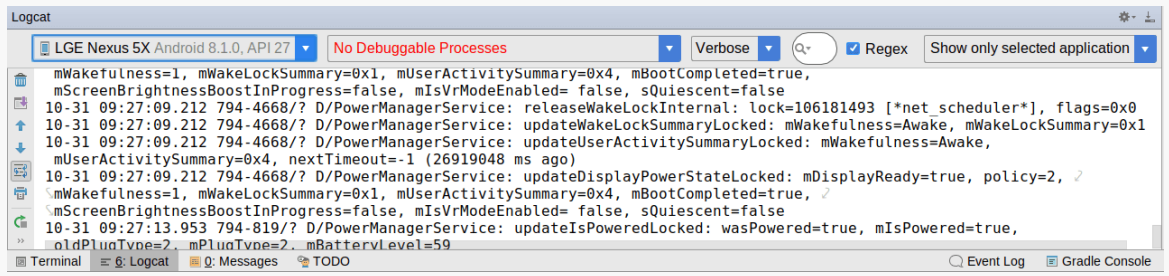

Figure 104: Android DDMS Tool Window, Showing Logcat

Logcat will show your stack traces, diagnostic information from the operating system, and anything you wish to include via calls to static methods on the `android.util.Log` class. For example, `Log.e()` will log a message at error severity, causing it to be displayed in red.

If you want to send something from Logcat to somebody else, such as via an issue tracker, just highlight the text and copy it to the clipboard, as you would with any text editor.

The "trash can" icon atop the tool strip on the left is the "clear log" tool. Clicking it will appear to clear Logcat. It definitely clears your Logcat *view*, so you will only see messages logged after you cleared it. Note, though, that this does not actually clear the logs from the device or emulator.

In addition, you can:

- Use the "Log level" drop-down to filter lines based on severity, where messages for your chosen severity or higher will be displayed
- Use the search field to the right of the "Log level" drop-down to filter items based on a search string
- Set up more permanent filters via the drop-down to the right of the search field

The Case of the Confounding Class Cast

If you crash, the stack trace might suggest that there is a problem tied to your resources. One common flavor of this is a `ClassCastException` when you call `findViewById()`. For example, you might call `(Button)findViewById(R.id.button)`, yet get a `ClassCastException: android.widget.LinearLayout` as a result,

indicating that while you thought your `findViewById()` call would return a `Button`, it really returned a `LinearLayout`.

Often times, this is not your fault. Sometimes, the `R` values get out of sync with pre-compiled classes from previous builds. This most often occurs just after you change your mix of resources (e.g., add a new layout).

To resolve this, you need to clean your project. To do this, in Android Studio, choose "Build > Clean Project" from the main menu.

So, if you get a strange crash that seems like it might be related to resources, clean your project. If the problem goes away, you are set — if the problem persists, you will need to do a bit more debugging.

Point Break

One of the hallmarks of Java IDEs is the ability to do real-time debugging, using breakpoints and the like. In that respect, Android Studio works for Android apps in the same way that IntelliJ IDEA and Eclipse work for Java apps. You can debug on an emulator or any Android device for which you enabled USB debugging (as you may have done in Tutorial #1).

Lacking any Android Studio-specific documentation, you will wind up referring to the documentation for IntelliJ IDEA to learn how to use its debugger.

With Android Studio, the run controls in the toolbar will give you some options for debugging your app:

Figure 105: Android Studio Run Controls

The bug-shaped button to the right of the "run" green triangle will launch your app and attach the debugger, so breakpoints will be honored. If your app is already running, and you want to debug the running process, you can do that via the toolbar button that looks like a phone with a small bug in the lower-right corner.

The Classic Container Classes

Containers — sometimes referred to as layout managers — organize widgets on the screen. Containers position and size widgets based upon rules that you supply along with key device characteristics, such as available screen size.

Three containers have dominated Android app development since Android's introduction in late 2007: `LinearLayout`, `RelativeLayout`, and `TableLayout`. This chapter focuses on those. Later chapters will explore other container classes, such as 2016's `ConstraintLayout`.

Introducing the Sampler App

The `Containers/Sampler` sample project has a bunch of layout resources that this chapter will use to illustrate how these containers work.

If you were to run this sample app, you would see a series of tabs, with one layout displayed per tab:

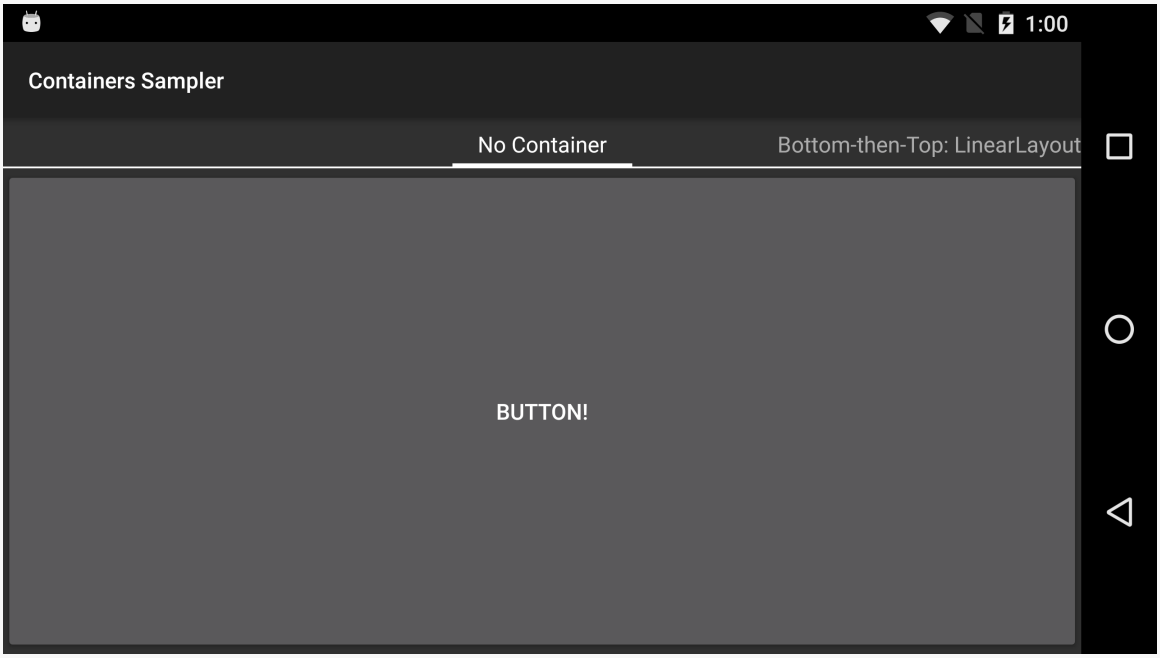

Figure 106: Sampler App, As Initially Launched

We are not going to get into the Java code associated with this sample app in this chapter. That code relies on other topics, like fragments and the `ViewPager` widget, that we have not gotten to yet. We will come back to this sample app and see how the tabs were implemented then. For now, the focus is on the layout files showing specific techniques for using these classic containers.

RTL and Your Layouts

Most of the world's languages are written left-to-right. So, in this paragraph, you read the letters and words starting from the left edge of a line across to the right edge.

Arabic and Hebrew, among others, are written right-to-left. The abbreviation "RTL" refers to these languages.

Originally, Android was focused purely on left-to-right (LTR) languages. As a result, you see attributes referring to things with respect to left and right (e.g., `android:paddingLeft`).

Slowly, Android improved its RTL support. In particular, starting with API Level 17 (Android 4.2), analogue attributes were added, replacing "left" with "start" and

"right" with "end". When using "start"/"end" attributes (e.g., `android:paddingStart`), "start" refers to where you start reading a line of text, and "end" refers to where you end reading a line of text:

Language Direction	"Start" Means...	"End" Means...
LTR	Left	Right
RTL	Right	Left

In general, we want the GUI to flow with the language direction. Things that you might have on the left with an LTR language usually go on the right with an RTL language, and so forth.

However, since these "start" and "end" attributes are new to API Level 17, you cannot use them on older devices. Sometimes, we will wind up either using the old "left"/"right" attributes or using both types of attributes, to cover all device versions.

We will revisit RTL language support a bit later in this chapter.

LinearLayout and the Box Model

`LinearLayout` represents Android's approach to a box model — widgets or child containers are lined up in a column or row, one after the next.

Concepts and Attributes

To configure a `LinearLayout`, you have four main areas of control besides the container's contents: the orientation, the fill model, the weight, the gravity.

Orientation

Orientation indicates whether the `LinearLayout` represents a row or a column. Just add the `android:orientation` property to your `LinearLayout` element in your XML layout, setting the value to be `horizontal` for a row or `vertical` for a column.

The orientation can be modified at runtime by invoking `setOrientation()` on the `LinearLayout`, supplying it either `HORIZONTAL` or `VERTICAL`.

Fill Model

The point behind a `LinearLayout` — or any of the Android container classes – is to organize multiple widgets. Part of organizing those widgets is determining how much space each gets.

`LinearLayout` takes an "eldest child wins" approach towards allocating space. So, if we have a `LinearLayout` with three children, the first child will get its requested space. The second child will get its requested space, if there is enough room remaining, and likewise for the third child. So if the first child asks for all the space (e.g., this is a `horizontal` `LinearLayout` and the first child has `android:layout_width="match_parent"`), the second and third children will wind up with zero width.

Weight

But, what happens if we have two or more widgets that should split the available free space? For example, suppose we have two multi-line fields in a column, and we want them to take up the remaining space in the column after all other widgets have been allocated their space.

To make this work, in addition to setting `android:layout_width` (for rows) or `android:layout_height` (for columns), you must also set `android:layout_weight`. This property indicates what proportion of the free space should go to that widget. If you set `android:layout_weight` to be the same non-zero value for a pair of widgets (e.g., `1`), the free space will be split evenly between them. If you set it to be `1` for one widget and `2` for another widget, the second widget will use up twice the free space that the first widget does. And so on.

The weight for a widget is zero by default.

Another pattern for using weights is if you want to allocate sizes on a percentage basis. To use this technique for, say, a horizontal layout:

1. Set all the `android:layout_width` values to be `0` for the widgets in the layout
2. Set the `android:layout_weight` values to be the desired percentage size for each widget in the layout
3. Make sure all those weights add up to `100`

If you want to have space left over, not allocated to any widget, you can add an `android:weightSum` attribute to the `LinearLayout`, and ensure that the sum of the

android:layout_weight attributes of the children are less than that sum. The children will each get space allocated based upon the ratio of their android:layout_weight compared to the android:weightSum, not compared to the sum of the weights. And there will be empty space that takes up the rest of the room not allocated to the children.

Gravity

By default, everything in a LinearLayout is start- and top-aligned. So, if you create a row of widgets via a horizontal LinearLayout, the row will be flush on the start side of the screen (e.g., left in a LTR language).

If that is not what you want, you need to specify a gravity. Unlike the physical world, Android has two types of gravity: the gravity of a widget within a LinearLayout, and the gravity of the contents of a widget or container.

The android:gravity property of some widgets and containers — which also can be defined via setGravity() in Java — tells Android to slide the contents of the widget or container in a particular direction. For example, android:gravity="right" says to slide the contents of the widget to the right; android:gravity="right|bottom" says to slide the contents of the widget to the right and the bottom.

Here, "contents" varies. TextView supports android:gravity, and the "contents" is the text held within the TextView. LinearLayout supports android:gravity, and the "contents" are the widgets inside the container. And so on.

Children of a LinearLayout also have the option of specifying android:layout_gravity. Here, the child is telling the LinearLayout "if there is room, please slide me (and me alone) in this direction". However, this only works in the direction *opposite* the orientation of the LinearLayout – the children of a vertical LinearLayout can use android:layout_gravity to control their positioning horizontally (start or end), but not vertically.

For a row of widgets, the default is for them to be aligned so their texts are aligned on the baseline (the invisible line that letters seem to "sit on"), though you may wish to specify a gravity of center_vertical to center the widgets along the row's vertical midpoint.

Android Studio Graphical Layout Editor

The `LinearLayout` container can be found in the "Layouts" portion of the Palette of the Android Studio graphical layout editor:

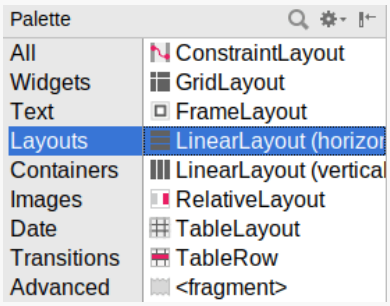

Figure 107: Layouts Palette in Android Studio Graphical Layout Editor

You can drag either the "LinearLayout (vertical)" or "LinearLayout (horizontal)" into a layout XML resource, then start dragging in children to go into the container.

When your `LinearLayout` is the selected widget, a few new toolbar buttons will appear over the preview:

Figure 108: LinearLayout Toolbar Buttons

The only one of these that works is the left hand one, which toggles the `LinearLayout` between `vertical` and `horizontal` orientation.

When one of the *children* of the `LinearLayout` is the selected widget, the toolbar changes:

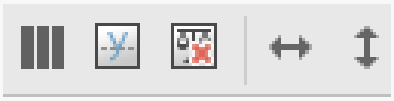

Figure 109: LinearLayout Toolbar Buttons, For Selected Child

From left to right, the buttons:

- Toggle the parent `LinearLayout` between horizontal and vertical orientations
- Align the child widgets' baselines (where a "baseline" is the invisible line that text appears to sit upon)
- Removes the `android:layout_weight` attribute, if it has one
- Toggle the width between `match_parent` and `wrap_content`
- Toggle the height between `match_parent` and `wrap_content`

Example: Bottom-then-Top

Those rules will make more sense once we work through some examples.

The first example is where we have two widgets. One widget should take up its "natural" amount of space, anchored to the bottom of the screen. The other widget should fill all the remaining space:

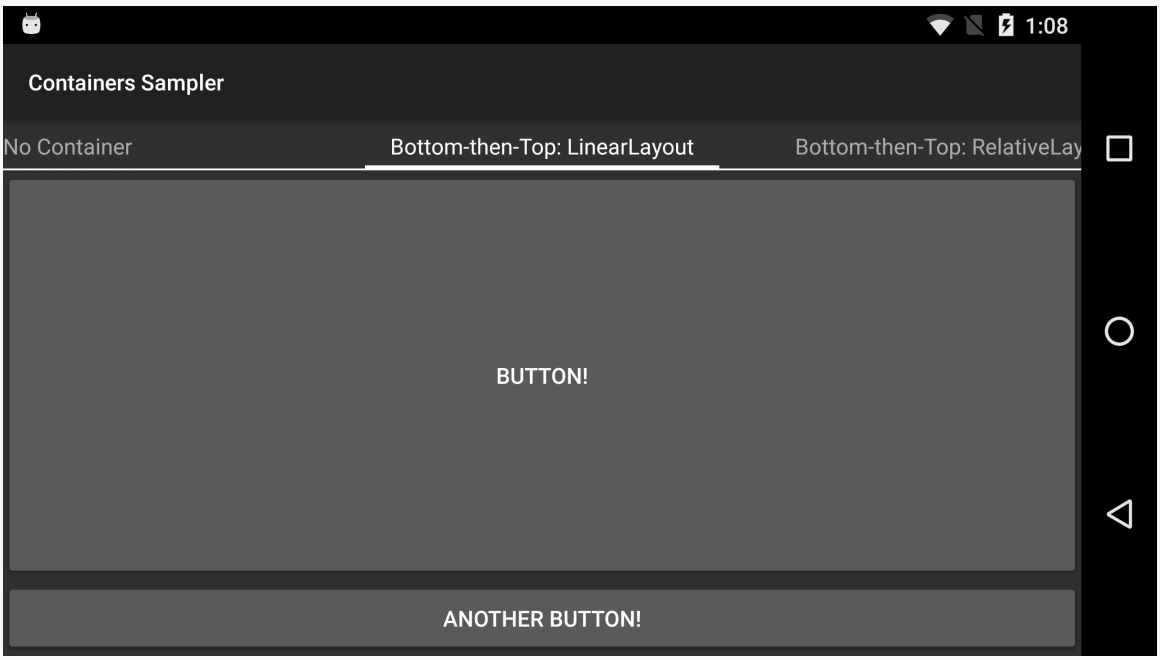

Figure 110: Bottom-then-Top Layout, Using LinearLayout

The XML

The layout XML that generated that screenshot consists of a `vertical` `LinearLayout` and two `Button` widgets:

```
<?xml version="1.0" encoding="utf-8"?>
<LinearLayout xmlns:android="http://schemas.android.com/apk/res/android"
  android:layout_width="match_parent"
  android:layout_height="match_parent"
  android:orientation="vertical"
  android:baselineAligned="false">

  <Button
    android:layout_width="match_parent"
    android:layout_height="0dp"
    android:layout_weight="1"
    android:text="@string/button" />

  <Button
    android:layout_width="match_parent"
    android:layout_height="wrap_content"
    android:text="@string/another_button" />
</LinearLayout>
```

(from Containers/Sampler/app/src/main/res/layout/bottom_then_top_ll.xml)

The `LinearLayout` has its sizes (`android:layout_width`, `android:layout_height`) set each to `match_parent`, so it will fill up all space available to it. In this sample app, that will be everything below the tabs.

Both `Button` widgets have their `android:layout_width` attributes also set to `match_parent`, so they will fill up all available space on the screen horizontally.

The bottom `Button` has its `android:layout_height` set to `wrap_content`, so it will only take up as much space as is needed to render its caption and background around it.

The top `Button` has `android:layout_height` set to `0dp`. If we did not do anything else, that would result in an impossibly-short button. However, we also have `android:layout_weight="1"`.

When this gets rendered on the screen, `LinearLayout` will make two passes through its children. On the first pass, it asks for how much space each child wants, based upon the `android:layout_height` values (since this is a `vertical` `LinearLayout`). The first `Button` will ask for 0 pixels of space, while the bottom `Button` will ask for however much it needs for its content. Then, the second pass of the `LinearLayout` through its children asks for their weights. The first `Button` has a weight of 1, while the bottom `Button` has the default weight of 0. As a result, the top `Button` gets 1/1 =

100% of all pixels left over from what the first pass used. This causes the top `Button` to become tall, shoving the bottom `Button` to the bottom of the screen.

Android Studio Graphical Layout Editor

You can create a new layout resource by right-clicking over the `res/layout/` directory and choosing "New > Layout resource file" from the right-mouse context menu. You then get a dialog where you can give the new resource a name and choose the root container for that layout:

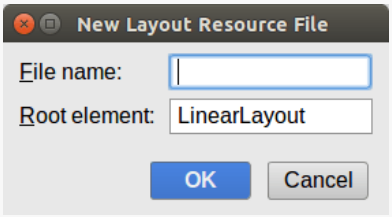

Figure 111: New Layout Resource Dialog

What you get by default depends a bit on your project:

- If your project has `ConstraintLayout` available to it, the default will be a `ConstraintLayout`
- Otherwise, the default will be a `vertical` `LinearLayout`

As you drag `Button` widgets into the layout, they are initially given a width of `match_parent` and a height of `wrap_content`:

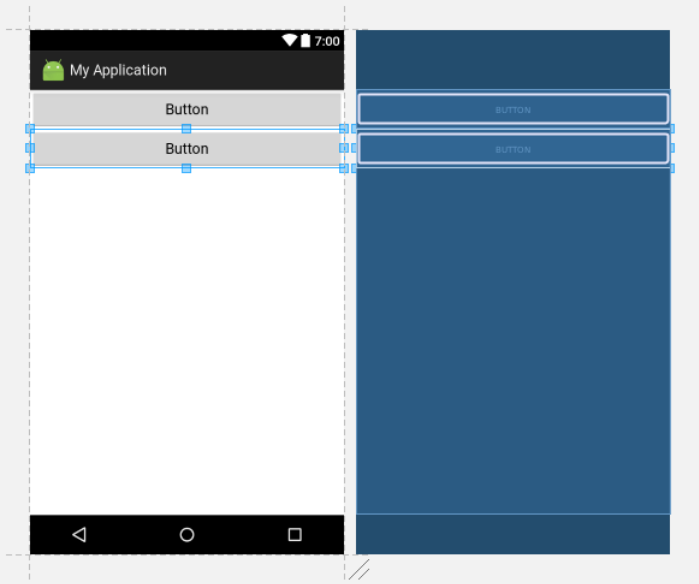

Figure 112: Vertical LinearLayout, with Two Button Widgets

Clicking the top button, then setting the `layout_weight` attribute to `1` in the Attributes pane, gives the desired look:

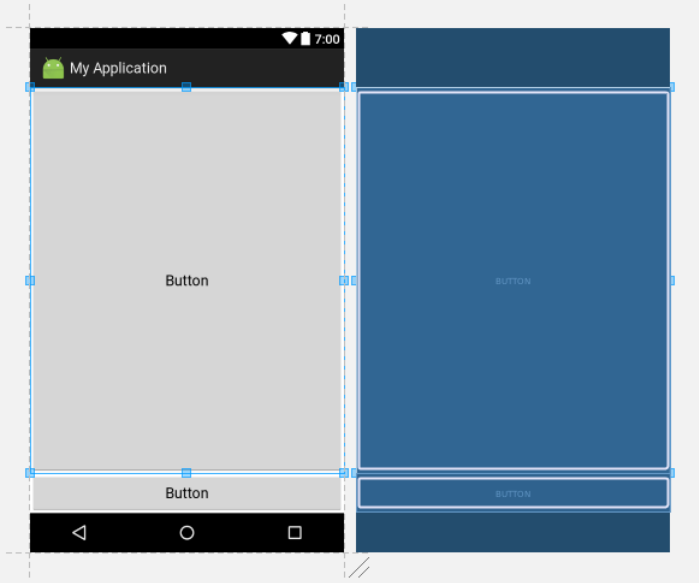

Figure 113: Vertical LinearLayout, with Weighted Button Widgets

Note that `layout_weight` may only appear for you in the "View all attributes" perspective of the Attributes pane, rather than in the simplified list.

Example: Stacked-Percent

Weights can get more elaborate than just giving all extra room to one widget.

The stacked-percent scenario allocates space on a percentage basis to all of the children of the `LinearLayout`. In the sample app, we have a layout file with three buttons, taking up 50%, 30%, and 20% of the space in a `vertical` `LinearLayout`:

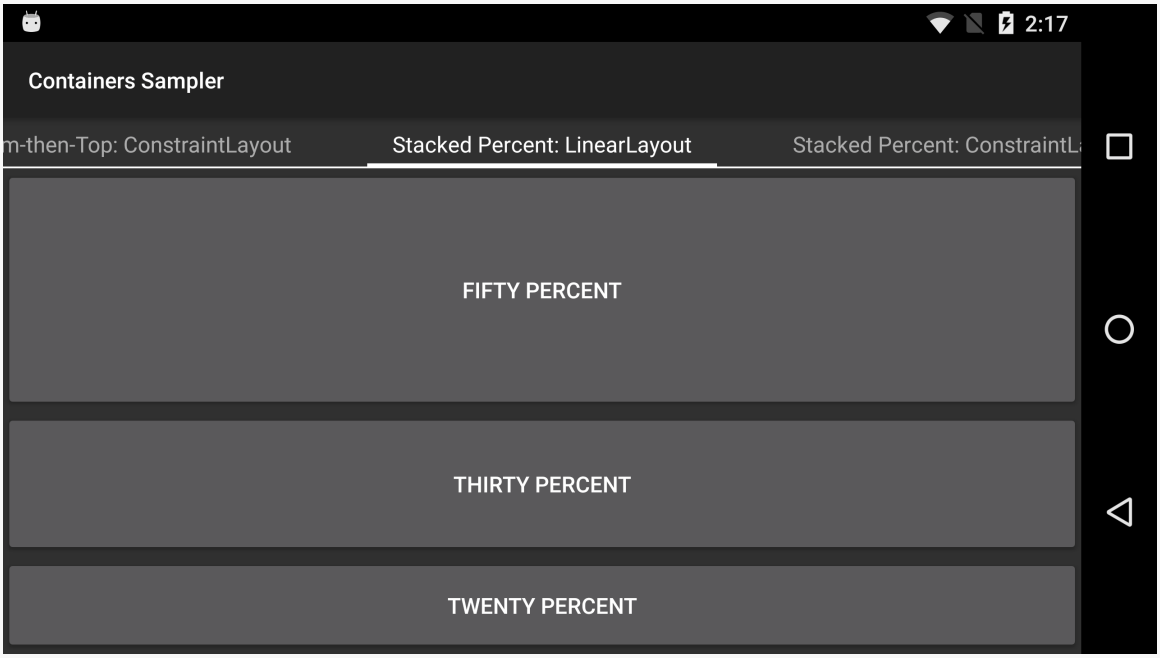

Figure 114: Stacked-Percent Layout, Using LinearLayout

The XML

This time, the layout resource XML has all three `Button` widgets with heights of 0:

```
<?xml version="1.0" encoding="utf-8"?>
<LinearLayout xmlns:android="http://schemas.android.com/apk/res/android"
  android:layout_width="match_parent"
  android:layout_height="match_parent"
  android:orientation="vertical">

  <Button
    android:layout_width="match_parent"
    android:layout_height="0dp"
    android:layout_weight="50"
```

```
    android:text="@string/fifty_percent"/>

  <Button
    android:layout_width="match_parent"
    android:layout_height="0dp"
    android:layout_weight="30"
    android:text="@string/thirty_percent"/>

  <Button
    android:layout_width="match_parent"
    android:layout_height="0dp"
    android:layout_weight="20"
    android:text="@string/twenty_percent"/>

</LinearLayout>
```

(from Containers/Sampler/app/src/main/res/layout/stacked_percent_ll.xml)

So, the first pass that the `LinearLayout` makes through its children, each child asks for 0 pixels of height, meaning that all of the `LinearLayout` space is available for the second pass.

On the second pass, the children report weights of 50, 30, and 20, respectively. 50+30+20=100, so the top `Button` gets 50/100 (50%) of the space, the middle `Button` gets 30/100 (30%) of the space, and the bottom `Button` gets 20/100 (20%) of the space.

Note that you would get the same results with weights of 5, 3, and 2. Really, it is the ratios of the weights that matter. However, if you are used to thinking in terms of percentages — perhaps due to past experience with other GUI toolkits — you can use integer percentages if you want.

Android Studio Graphical Layout Editor

Constructing this using the graphical layout editor is similar to the previous example:

- Create the new layout resource, choosing a `LinearLayout` as the root container.
- Drag three `Button` widgets into the `LinearLayout`.
- Using the Attributes pane, set the `android:layout_height` values on the three `Button` widgets to `0dp`

- Using the Attributes pane, set the `android:layout_weight` values to the three `Button` widgets. Note, as before, that the weight may not be on the condensed attributes list. You may need to view all attributes to have access to it:

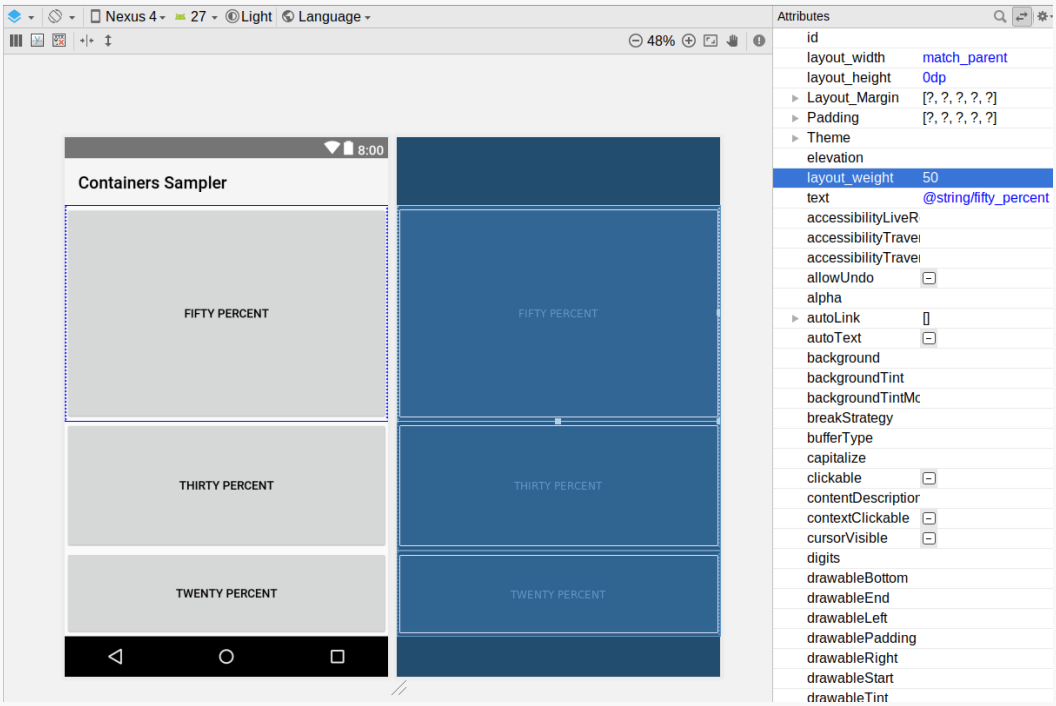

Figure 115: Vertical LinearLayout, with Full Attributes List

Example: URL Dialog

Of course, you are not limited to one axis. You can nest `LinearLayout` widgets to structure things along both the X and the Y axis.

For example, you might be aiming for a dialog-style form like this:

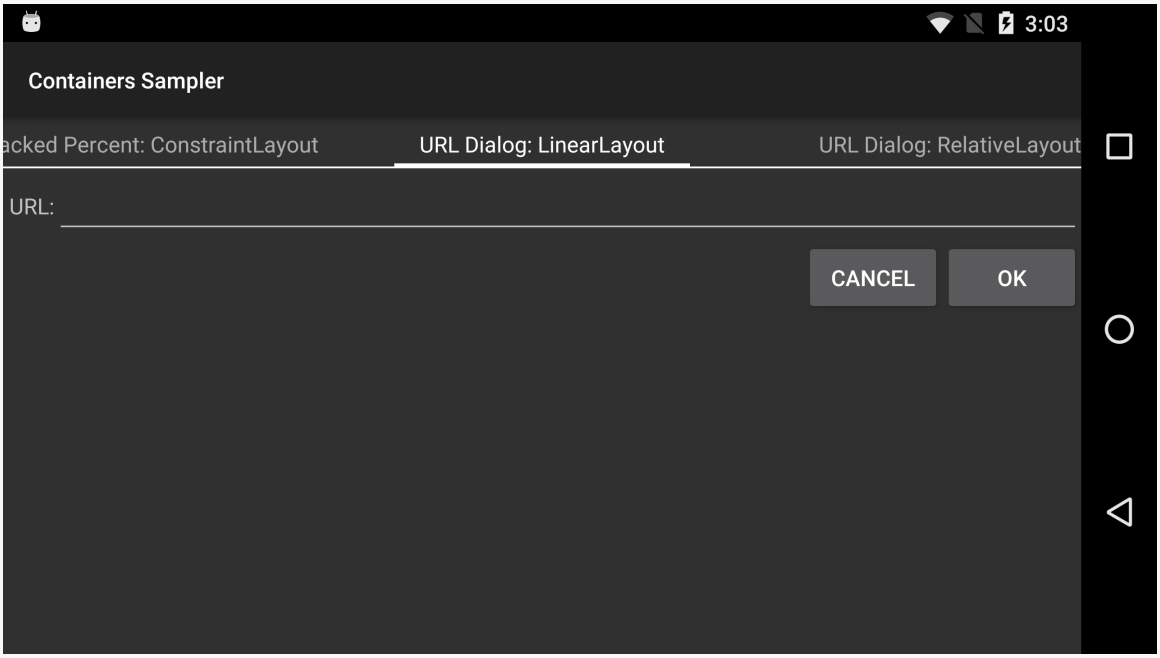

Figure 116: URL-Dialog Layout, Using LinearLayout

The XML

This layout resource is a bit more complicated, as we are now up to four widgets plus three `LinearLayout` containers:

```
<?xml version="1.0" encoding="utf-8"?>
<LinearLayout xmlns:android="http://schemas.android.com/apk/res/android"
  android:layout_width="match_parent"
  android:layout_height="wrap_content"
  android:orientation="vertical">

  <LinearLayout
    android:layout_width="match_parent"
    android:layout_height="wrap_content"
    android:orientation="horizontal">

    <TextView
      android:layout_width="wrap_content"
      android:layout_height="wrap_content"
      android:layout_marginLeft="4dp"
      android:layout_marginStart="4dp"
      android:text="@string/url" />

    <EditText
```

```
      android:id="@+id/entry"
      android:layout_width="match_parent"
      android:layout_height="wrap_content"
      android:inputType="text" />

  </LinearLayout>

  <LinearLayout
    android:layout_width="match_parent"
    android:layout_height="wrap_content"
    android:gravity="end"
    android:orientation="horizontal">

    <Button
      android:id="@+id/cancel"
      android:layout_width="wrap_content"
      android:layout_height="wrap_content"
      android:text="@string/cancel" />

    <Button
      android:id="@+id/ok"
      android:layout_width="wrap_content"
      android:layout_height="wrap_content"
      android:text="@string/ok" />
  </LinearLayout>

</LinearLayout>
```

(from Containers/Sampler/app/src/main/res/layout/url_dialog_ll.xml)

The outer `LinearLayout` is `vertical`, serving to stack the two `horizontal` `LinearLayout` rows. Each of those `horizontal` `LinearLayout` containers has a height of `wrap_content` and a width of `match_parent`, so they span the width of the screen but only need as much height as is required to render their widget contents.

The first of our four widgets is the `TextView`. Since it is in the first `horizontal` `LinearLayout`, it will be flush on the one side (left in a LTR language like English). However, we have `4dp` of margin, using both the older `android:layout_marginLeft` and the newer, RTL-capable `android:layout_marginStart` attributes. So, the widget is inset a bit from the edge.

The second widget is the `EditText`. It has a width of `match_parent`, so it will take over all remaining space after the `TextView`.

The bottom `LinearLayout` has `android:gravity="end"`, which will cause its contents to slide towards the end side of the `LinearLayout` (right in a LTR language like English). It contains the two `Button` widgets, and that is why the two `Button` widgets are slid over to the opposite end of the form.

Android Studio Graphical Layout Editor

Not surprisingly, the more complex the layout you want to create, the more work is required to create it. The IDE only helps to a point.

So, to construct this layout, you would need to:

- Create the new layout resource, choosing a `LinearLayout` as the root container.
- Drag a "LinearLayout (horizontal)" item from the Palette into the `vertical` `LinearLayout`. This unfortunately results in the new `LinearLayout` consuming all of the space of its parent, as its height and width are both `match_parent` by default:

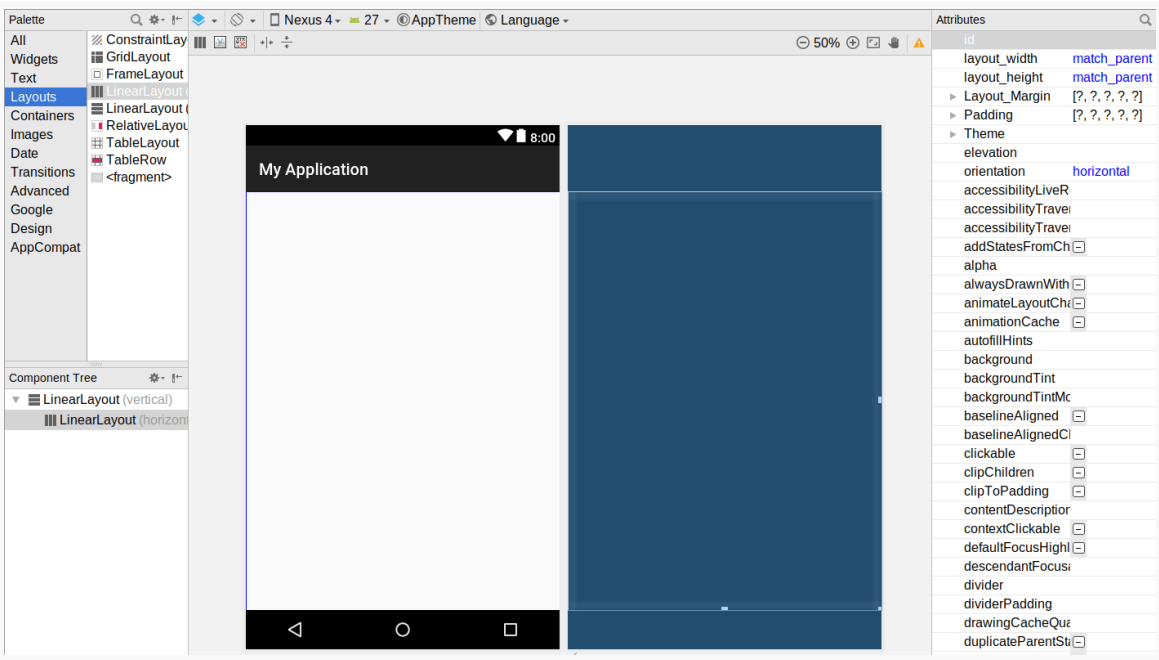

Figure 117: Vertical LinearLayout Holding Horizontal LinearLayout

- Using the Attributes pane, set the padding to be `8dp` on all sides:

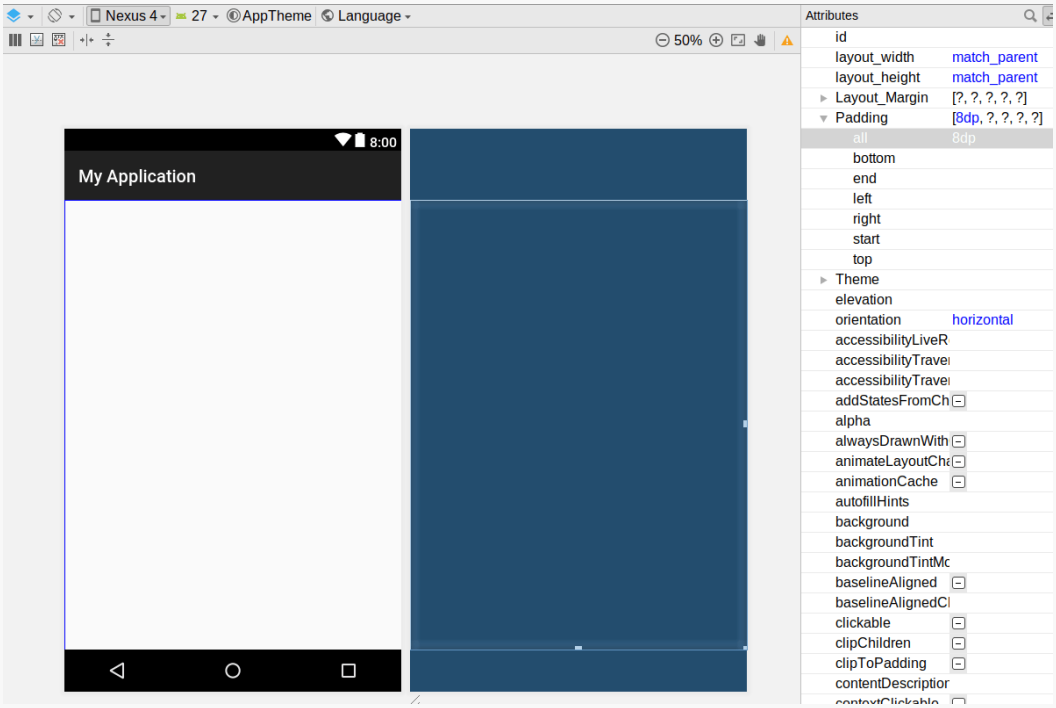

Figure 118: 8dp Padding on the Horizontal LinearLayout

- Drag a `TextView` into the `horizontal LinearLayout` *in the Component Tree*, and set its `text` to `URL:`, its width to `wrap_content`, and remove its `layout_weight` value:

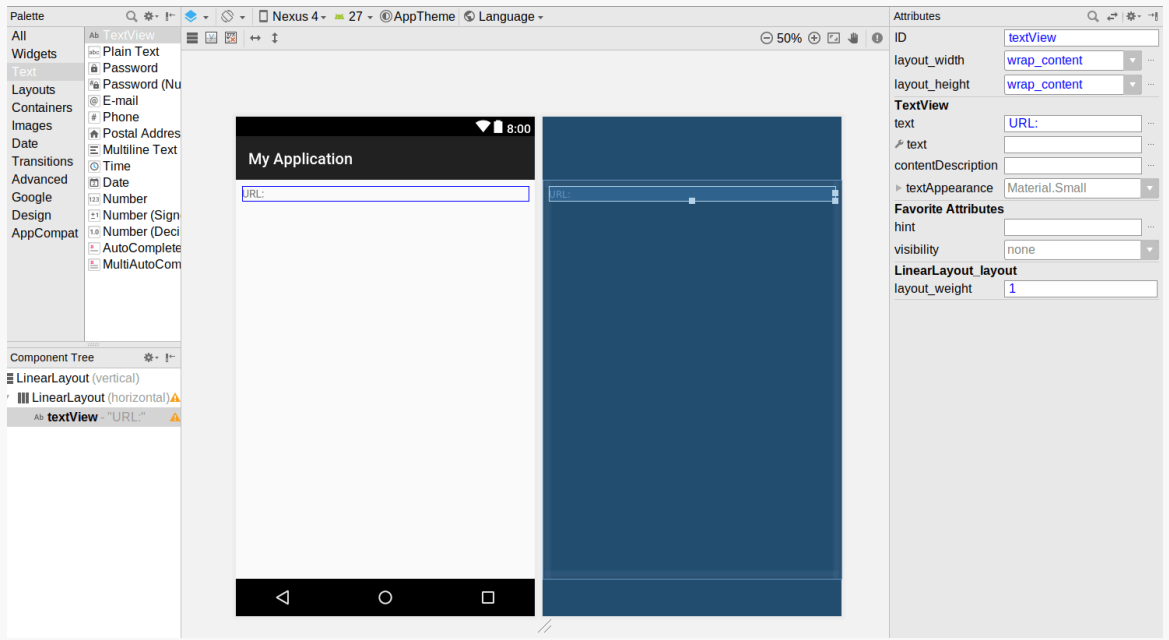

Figure 119: Horizontal LinearLayout with TextView

- Drag a "Plain Text" `EditText` into the `horizontal LinearLayout`, setting its width to be `match_parent`, its `text` to be empty, its `inputType` to be something appropriate (e.g., `textUri`, since in theory this field should hold a URL), and remove its weight. Note that you may find it easier to drag the widget into its container via the Component Tree tool, as you can better control the order of the children that way:

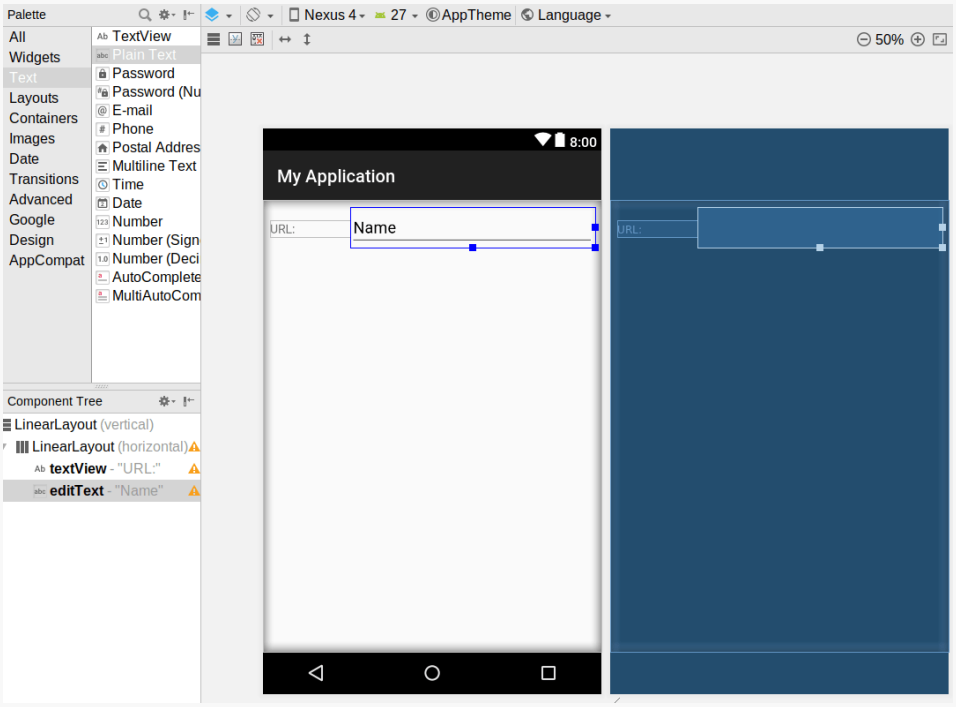

Figure 120: Horizontal LinearLayout with TextView and EditText

- Drag another "LinearLayout (horizontal)" item from the Palette, but this time drop it on the "LinearLayout(vertical)" in the Component Tree, then reordering the children in the Component Tree to put the new `LinearLayout` at the bottom:

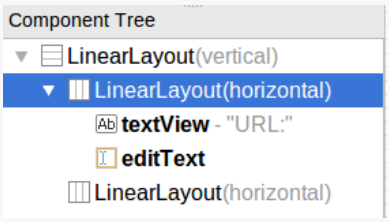

Figure 121: Component Tree with Two Horizontal LinearLayouts

- Adjust the height of both `LinearLayout` widgets to be `wrap_content`.
- Drag two `Button` widgets into that lower `LinearLayout` in the Component Tree:

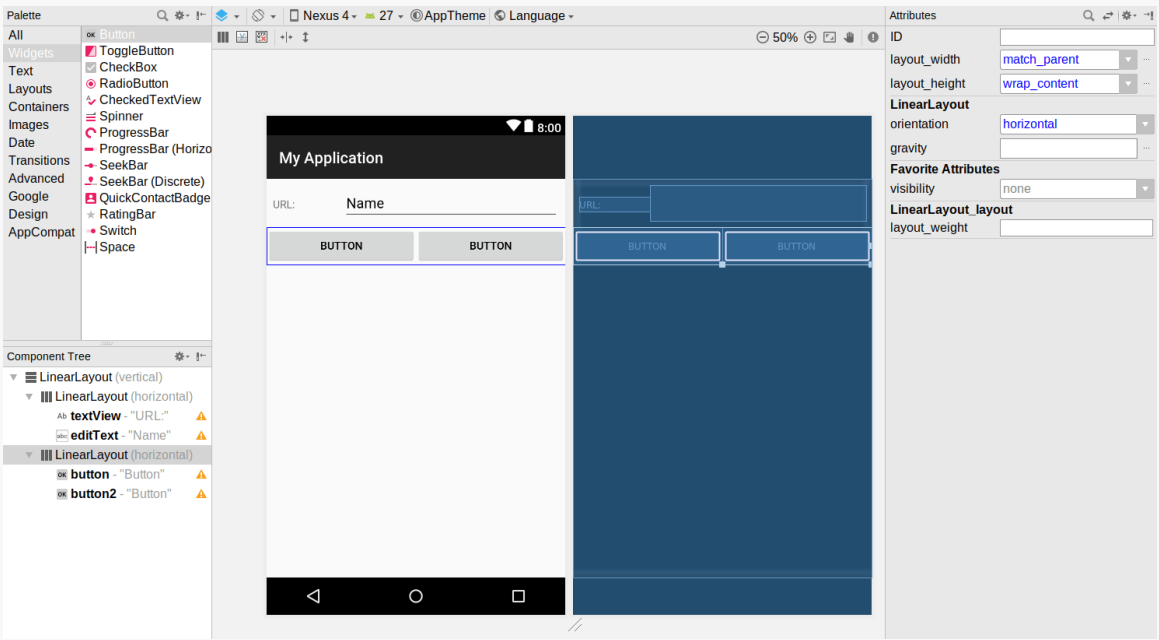

Figure 122: Two Buttons in Lower Horizontal LinearLayout

- Remove the weights from both `Button` widgets via the Attributes pane:

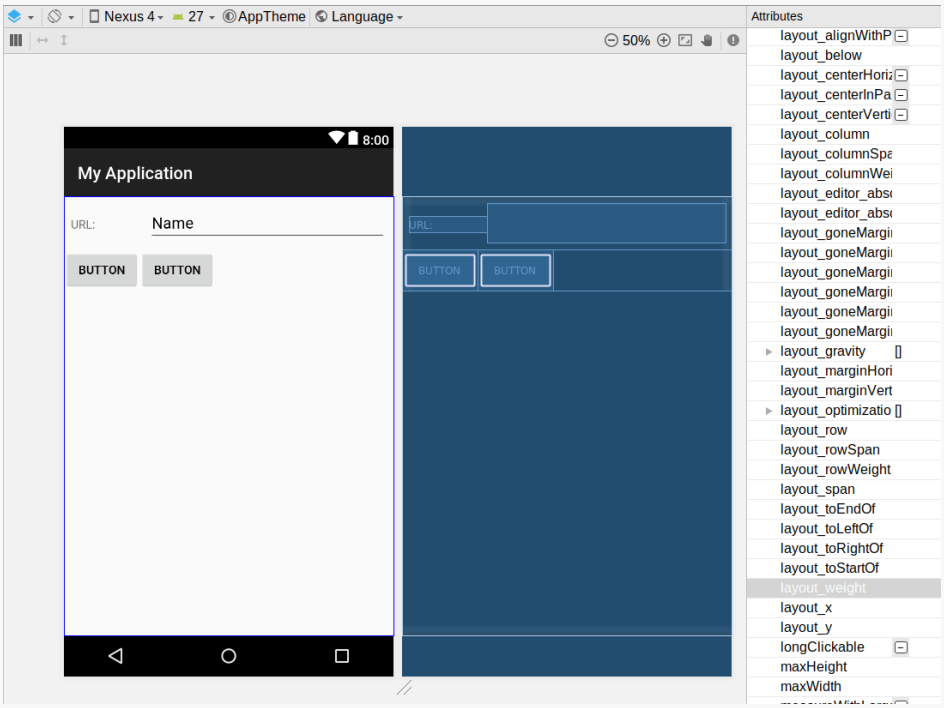

Figure 123: Two Smaller Buttons in Lower Horizontal LinearLayout

- Change the `gravity` of the lower `horizontal` `LinearLayout` to be `end`, using the Attributes pane:

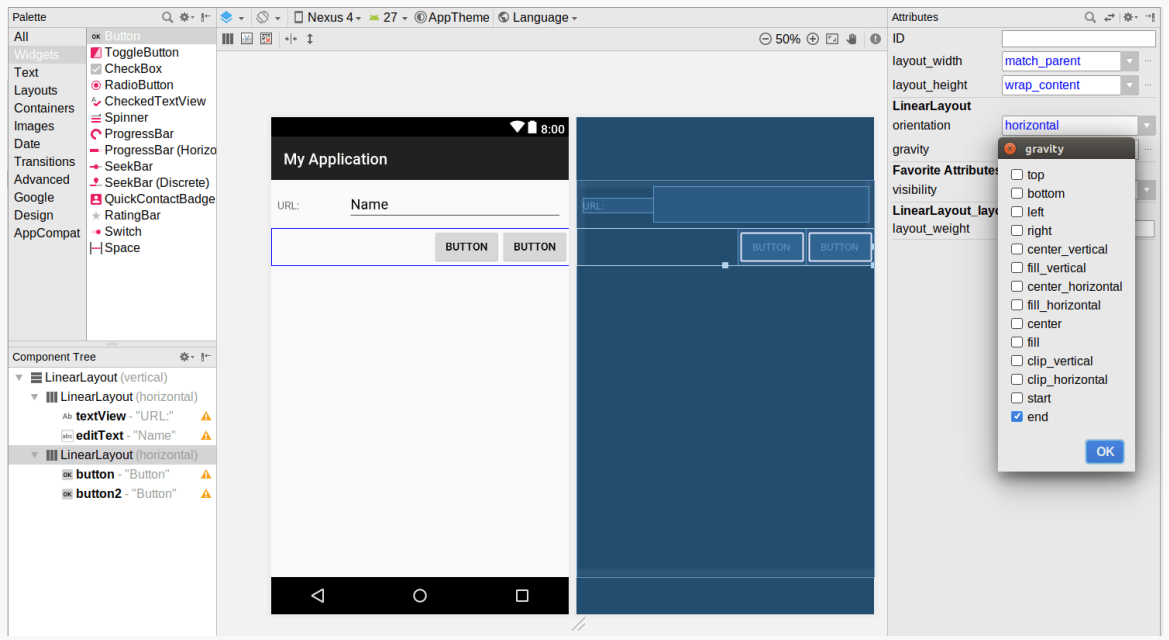

Figure 124: Two Smaller Right-Flush Buttons in Lower Horizontal LinearLayout

- Change the captions on the buttons to “OK” and “Cancel”:

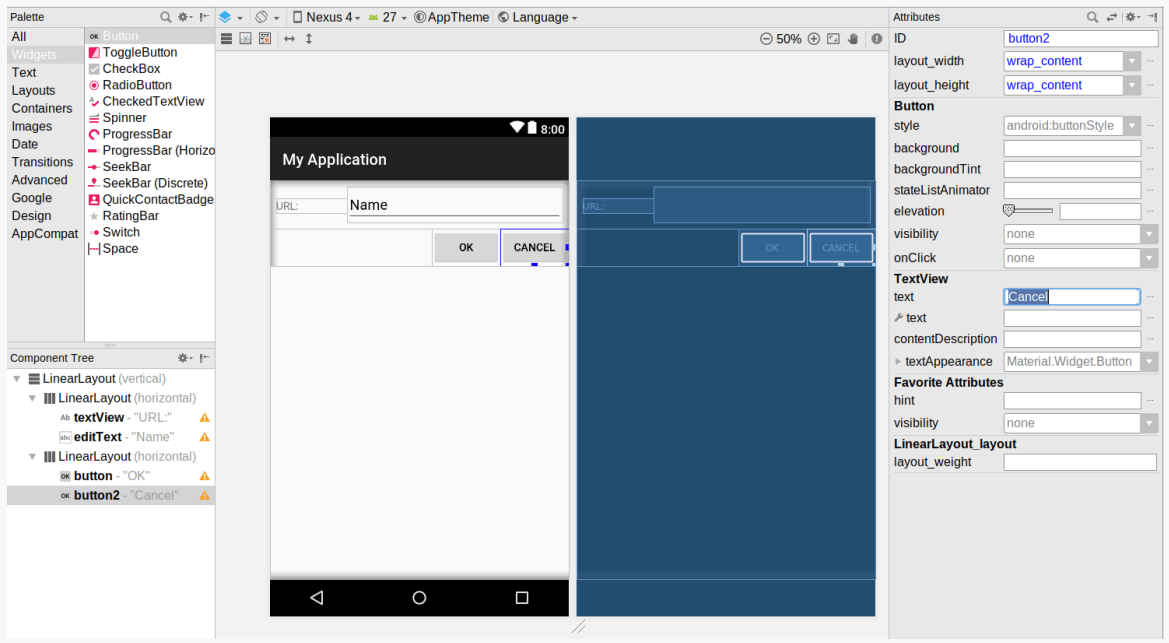

Figure 125: Buttons with Desired Captions

Now, having done all of that, the right-most toolbar button above the preview and blueprint will now be a yellow triangle, indicating some warnings about the layout that we built. Tapping that icon will display a pane with messages explaining what Android Studio does not like:

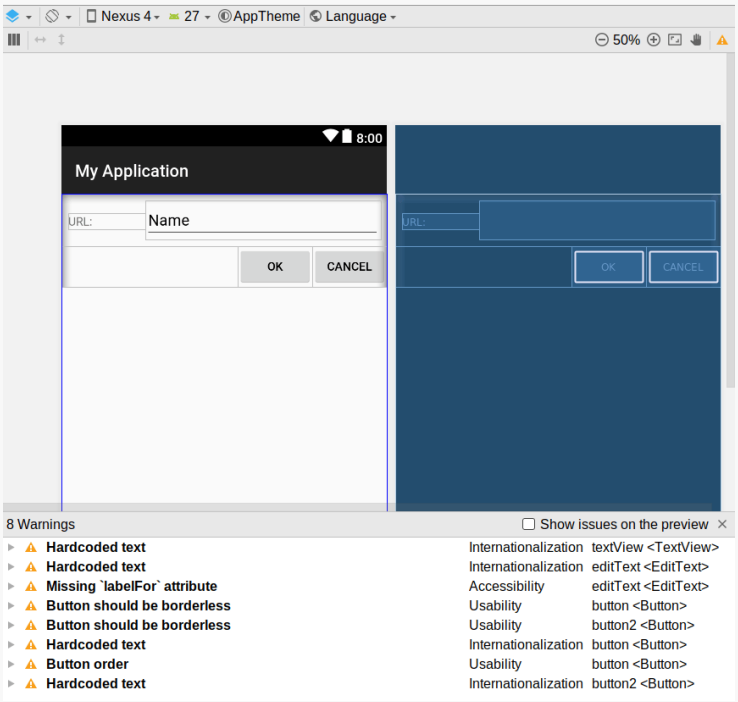

Figure 126: Layout Warning Messages

Each of the warnings in the list usually has an explanation, some suggested fixes, and other explanatory information. Clicking the button for a suggested fix will apply that fix and clear up that warning.

Some of the warnings may come from the captions for the `TextView` and `Button` widgets. If you just type a string into the `Attributes` pane, that fills in the literal string into the layout, and ideally we use string resources. For those, the "Extract string resource" suggested fix will allow you to define those as string resources.

Some of those warnings will be about certain things about styles (e.g., "Buttons in button bars should be borderless"). While in the long run you might care about those warnings, in the short term, while you are learning Android, ignoring the warnings using the suggested fix is a good idea.

One of those warnings will be about a missing `android:labelFor` attribute, which is part of the accessibility support system in Android, which we will explore later. Another is about the order of the buttons, which Google disagrees with.

Example: A Bigger Form

Not everything in a form has to be inside a `horizontal LinearLayout` which is itself inside a `vertical LinearLayout`. You only need a `horizontal LinearLayout` when you have a row that contains two or more widgets. For single-widget rows, they can just be simple children of `vertical LinearLayout`.

For example, perhaps you have a more elaborate form in mind, with several fields and other widgets, like this one:

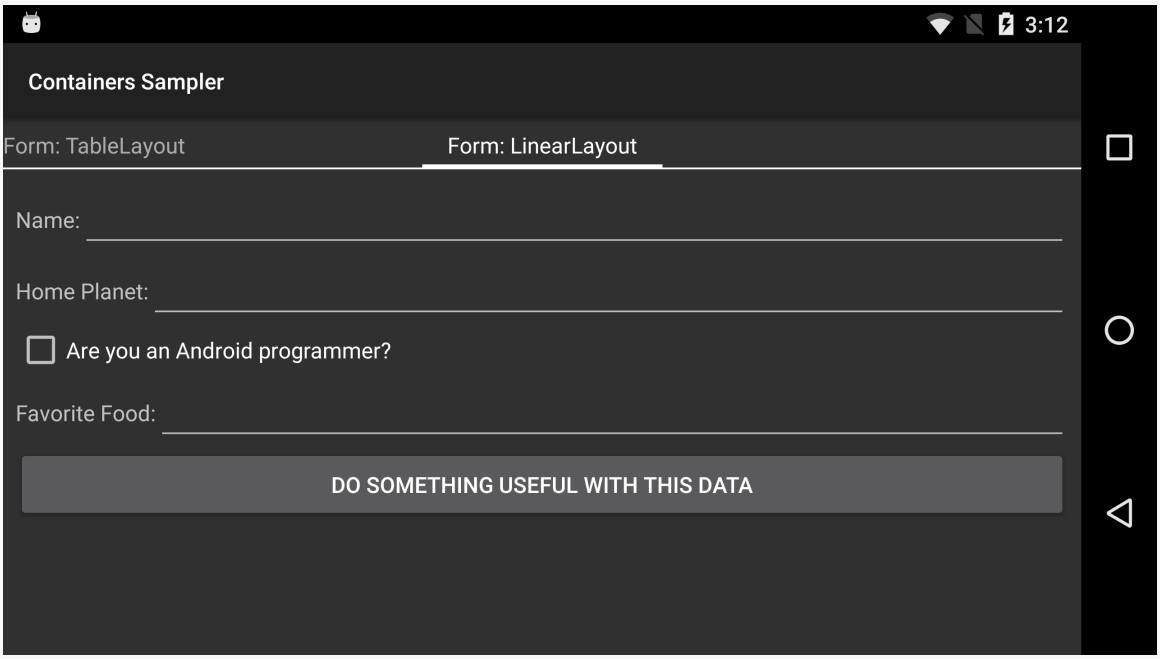

Figure 127: Form Layout, Using LinearLayout

The XML

The form's layout resource resembles the URL-dialog scenario from earlier:

```
<?xml version="1.0" encoding="utf-8"?>
<LinearLayout xmlns:android="http://schemas.android.com/apk/res/android"
  android:layout_width="match_parent"
  android:layout_height="match_parent"
  android:orientation="vertical"
  android:padding="8dp">

  <LinearLayout
```

```
    android:layout_width="match_parent"
    android:layout_height="wrap_content"
    android:orientation="horizontal">
    <TextView
      android:layout_width="wrap_content"
      android:layout_height="wrap_content"
      android:text="@string/name" />
    <EditText
      android:layout_width="match_parent"
      android:layout_height="wrap_content"
      android:inputType="text" />
</LinearLayout>

<LinearLayout
    android:layout_width="match_parent"
    android:layout_height="wrap_content"
    android:orientation="horizontal">
    <TextView
      android:layout_width="wrap_content"
      android:layout_height="wrap_content"
      android:text="@string/home_planet" />
    <EditText
      android:layout_width="match_parent"
      android:layout_height="wrap_content"
      android:inputType="text" />
</LinearLayout>

<CheckBox
    android:layout_width="match_parent"
    android:layout_height="wrap_content"
    android:text="@string/android_programmer" />

<LinearLayout
    android:layout_width="match_parent"
    android:layout_height="wrap_content"
    android:orientation="horizontal">
    <TextView
      android:layout_width="wrap_content"
      android:layout_height="wrap_content"
      android:text="@string/favorite_food" />
    <EditText
      android:layout_width="match_parent"
      android:layout_height="wrap_content"
      android:inputType="text" />
</LinearLayout>

<Button
    android:layout_width="match_parent"
```

```
    android:layout_height="wrap_content"
    android:text="@string/do_something" />

</LinearLayout>
```

(from Containers/Sampler/app/src/main/res/layout/form_ll.xml)

However, note that the `CheckBox` and the `Button` are not themselves wrapped in `horizontal` `LinearLayout` containers. They are merely direct children of the `vertical` `LinearLayout`. In this case, both are set to have a width of `match_parent`, though that is not required — you could have them set to `wrap_content` if you prefer.

We will look at `CheckBox` in greater detail in an upcoming chapter.

Android Studio Graphical Layout Editor

Setting up this form follows the same basic recipe as was used for the simpler dialog form from earlier in this chapter:

- Set up a layout resource rooted in a `vertical` `LinearLayout`
- Drag a `horizontal` `LinearLayout` into the `vertical` `LinearLayout`
- Drag a `TextView` and an `EditText` into the `horizontal` `LinearLayout` and configure as needed
- Repeat those last two steps for each of the other five rows

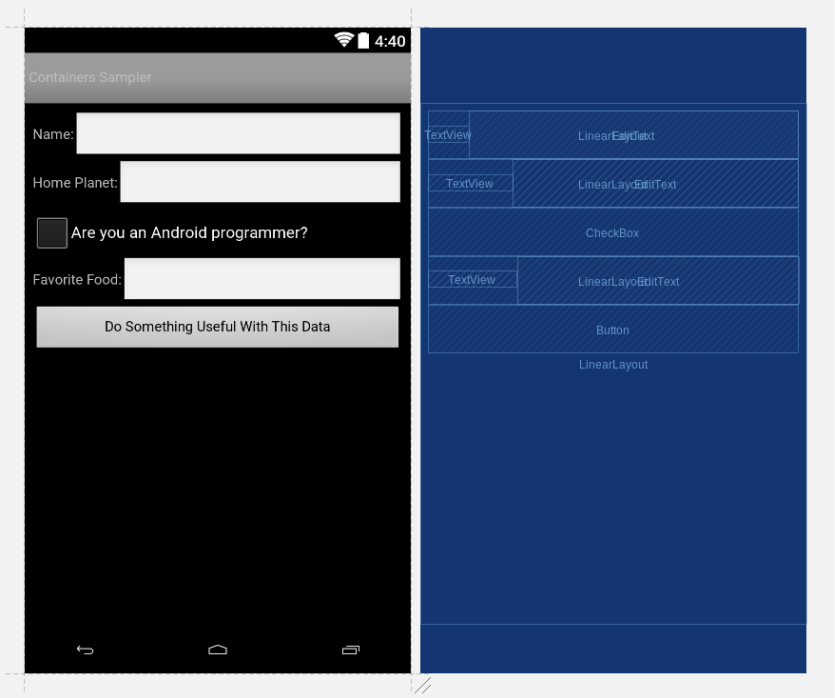

Figure 128: Bigger Form, As Seen in Android Studio

The Problem

If you look back at the screenshot, you will notice that the labeled `EditText` widgets are ragged, in terms of their layout. Each `EditText` immediately follows the `TextView` label, without regard to any sort of "columns". That is because each `LinearLayout` is largely independent. You cannot readily have one row depend upon the other rows.

A `TableLayout` would be a better choice for this sort of a form, as there we can have distinct columns of labels and fields. We will see how `TableLayout` handles this structure later in this chapter.

All Things Are Relative

`RelativeLayout`, as the name suggests, lays out widgets based upon their relationship to other widgets in the container and the parent container. You can place Widget X below and to the left of Widget Y, or have Widget Z's bottom edge align with the bottom of the container, and so on.

Concepts and Attributes

To make all this work, we need ways to reference other widgets within an XML layout file, plus ways to indicate the relative positions of those widgets.

Positions Relative to Container

The easiest relations to set up are tying a widget's position to that of its container:

1. `android:layout_alignParentTop` says the widget's top should align with the top of the container
2. `android:layout_alignParentBottom` says the widget's bottom should align with the bottom of the container
3. `android:layout_alignParentStart` says the widget's start side should align with the start side of the container
4. `android:layout_alignParentEnd` says the widget's end side should align with the end side of the container
5. `android:layout_centerHorizontal` says the widget should be positioned horizontally at the center of the container
6. `android:layout_centerVertical` says the widget should be positioned vertically at the center of the container
7. `android:layout_centerInParent` says the widget should be positioned both horizontally and vertically at the center of the container

All of these attributes take a simple boolean value (`true` or `false`). Also, there are `android:layout_alignParentLeft` and `android:layout_alignParentRight` attributes, for pre-Android 4.2 devices or for cases where you want to position irrespective of language direction.

Note that the padding of the widget is taken into account when performing these various alignments. The alignments are based on the widget's overall cell (combination of its natural space plus the padding).

Relative Notation in Attributes

The remaining attributes of relevance to `RelativeLayout` take as a value the identity of a widget in the container. To do this:

- Put identifiers (`android:id` attributes) on all elements that you will need to address

- Address these widgets from other widgets using the identifiers

The first occurrence of an id value should have the plus sign (`@+id/widget_a`); the second and subsequent times that id value is used in the layout file should drop the plus sign (`@id/widget_a`). This allows the build tools to better help you catch typos in your widget `id` values — if you do not have a plus sign for a widget `id` value that has not been seen before, that will be caught at compile time. For example, if Widget A appears in the `RelativeLayout` before Widget B, and Widget A is identified as `@+id/widget_a`, Widget B can refer to Widget A in one of its own attributes via the identifier `@id/widget_a`.

Positions Relative to Other Widgets

There are four attributes that control position of a widget *vis-à-vis* other widgets:

1. `android:layout_above` indicates that the widget should be placed above the widget referenced in the property
2. `android:layout_below` indicates that the widget should be placed below the widget referenced in the property
3. `android:layout_toStartOf` indicates that the widget should be placed to the start of the widget referenced in the property
4. `android:layout_toEndOf` indicates that the widget should be placed to the end of the widget referenced in the property

There are also `android:layout_toLeftOf` and `android:layout_toRightOf` attributes for use with older devices.

Beyond those four, there are five additional attributes that can control one widget's alignment relative to another:

1. `android:layout_alignTop` indicates that the widget's top should be aligned with the top of the widget referenced in the property
2. `android:layout_alignBottom` indicates that the widget's bottom should be aligned with the bottom of the widget referenced in the property
3. `android:layout_alignStart` indicates that the widget's starting edge should be aligned with the starting edge of the widget referenced in the property
4. `android:layout_alignEnd` indicates that the widget's ending edge should be aligned with the ending edge of the widget referenced in the property
5. `android:layout_alignBaseline` indicates that the baselines of the two widgets should be aligned (where the "baseline" is that invisible line that text appears to sit on)

The last one is useful for aligning labels and fields so that the text appears "natural". Since fields have a box around them and labels do not, `android:layout_alignTop` would align the top of the field's box with the top of the label, which will cause the text of the label to be higher on-screen than the text entered into the field.

Android Studio Graphical Layout Editor

You will find `RelativeLayout` in the "Layouts" section of the Palette in the Android Studio Graphical Layout editor. You can drag that into your layout XML resource.

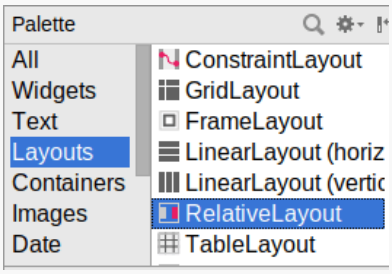

Figure 129: Layouts Section of Palette, RelativeLayout Highlighted

As you drag other widgets into your `RelativeLayout`, you will see arrows hinting at the rules that will be applied if you drop the widget at the current mouse location:

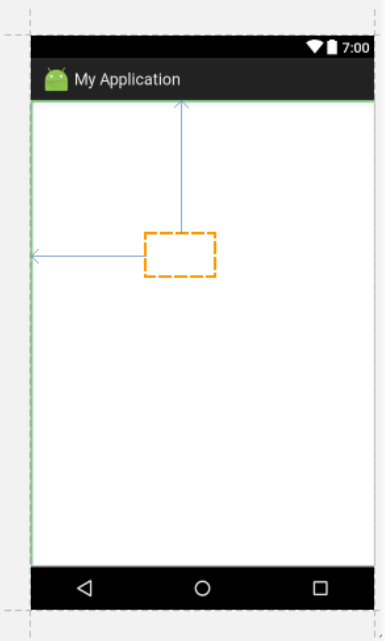

Figure 130: Dragging a Widget in a RelativeLayout

Getting the rules that you *want* may or may not be possible purely through drag-and-drop. You may need to just drop the widget into the `RelativeLayout` and manually adjust the rules, whether by using the Attributes pane or by editing the XML directly.

Example: Bottom-then-Top

Earlier in the chapter, we saw how to implement the bottom-then-top pattern using a `LinearLayout`, where we had a small button on the bottom and a large button on the top. The large button was set to take up all space that was not required by the small button.

We can achieve the same result using a `RelativeLayout`.

The XML

As with the `LinearLayout` scenario, we have one container plus the two `Button` widgets. In this case, the container is a `RelativeLayout`:

```
<?xml version="1.0" encoding="utf-8"?>
<RelativeLayout xmlns:android="http://schemas.android.com/apk/res/android"
```

```
  android:layout_width="match_parent"
  android:layout_height="match_parent">

  <Button
    android:layout_width="match_parent"
    android:layout_height="match_parent"
    android:layout_above="@+id/another_button"
    android:layout_alignParentTop="true"
    android:text="@string/button" />

  <Button
    android:id="@id/another_button"
    android:layout_width="match_parent"
    android:layout_height="wrap_content"
    android:layout_alignParentBottom="true"
    android:text="@string/another_button" />
</RelativeLayout>
```

(from Containers/Sampler/app/src/main/res/layout/bottom_then_top_rl.xml)

The bottom `Button` has the same size as before, with `android:layout_width` set to `match_parent` and `android:layout_height` set to `wrap_content`. However, it also has `android:layout_alignParentBottom="true"`, anchoring it to the bottom of the `RelativeLayout`. Since the `RelativeLayout` fills all available space, the bottom `Button` is anchored to the bottom of the screen, in effect.

The top `Button` has two `RelativeLayout` positioning attributes:

- `android:layout_above="@+id/another_button"`, so it is placed above the bottom `Button`
- `android:layout_alignParentTop="true"`, so it is anchored to the top of the `RelativeLayout`

Given these rules, it does not matter what the `android:layout_height` attribute value is. The `Button` will be stretched between those two anchor points: the top of the `RelativeLayout` and the top of the bottom `Button`.

Android Studio Graphical Layout Editor

By default, when creating a new layout resource file, you get either a `ConstraintLayout` or a `vertical LinearLayout` as the root element. You can change that by replacing the "Root element" value with any other widget or container class name, such as `RelativeLayout`:

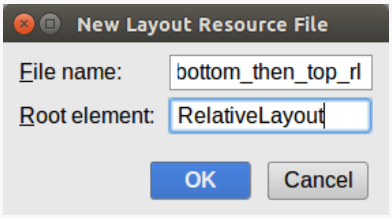

Figure 131: New Layout Resource with RelativeLayout

However, from there, using the drag-and-drop capabilities will start to be more of a pain than they are worth.

You can drag a `Button` into the `RelativeLayout`, for example:

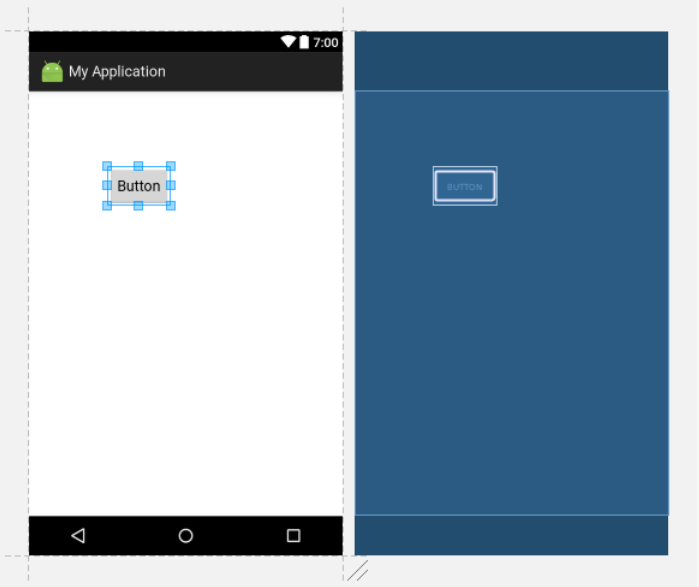

Figure 132: RelativeLayout and Button

However, you get no visual feedback after you drop the widget of what the rules are that the IDE chose, based on your drag-and-drop location. If you rummage through the Attributes pane, you will see that the rules are reflected in some checkbox attributes for the boolean `RelativeLayout` `android:layout_` attributes, plus margins based on how far from the `RelativeLayout` edges you placed the widget:

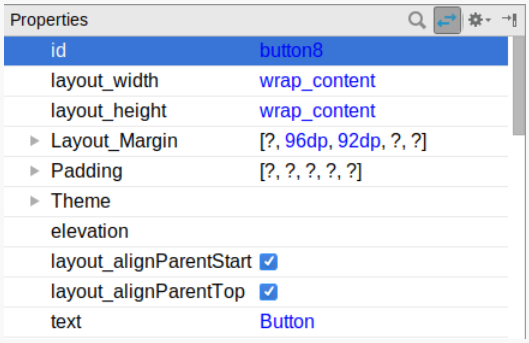

Figure 133: Button Attributes in RelativeLayout

Fixing those through the Attributes pane is no easier than is fixing them through the XML editor. Arguably, using the Attributes pane is slower.

Example: URL Dialog

We also used `LinearLayout` to create the "URL dialog" UI, where we had the labeled field along with "OK" and "Cancel" buttons. That same structure can also be built using a `RelativeLayout`.

With `LinearLayout`, we needed three containers: one `vertical` `LinearLayout` wrapped around two `horizontal` `LinearLayouts`. `RelativeLayout` is simpler from that standpoint, as we only need one `RelativeLayout`. The complexity moves into the widgets instead:

```
<?xml version="1.0" encoding="utf-8"?>
<RelativeLayout
  xmlns:android="http://schemas.android.com/apk/res/android"
  android:layout_width="match_parent"
  android:layout_height="wrap_content">

  <TextView
    android:id="@+id/label"
    android:layout_width="wrap_content"
    android:layout_height="wrap_content"
    android:layout_alignBaseline="@+id/entry"
    android:layout_alignParentLeft="true"
    android:layout_alignParentStart="true"
    android:layout_marginLeft="4dp"
    android:layout_marginStart="4dp"
    android:text="@string/url"/>

  <EditText
```

```
    android:id="@id/entry"
    android:layout_width="match_parent"
    android:layout_height="wrap_content"
    android:layout_alignParentTop="true"
    android:layout_toRightOf="@id/label"
    android:layout_toEndOf="@id/label"
    android:inputType="text"/>

  <Button
    android:id="@+id/ok"
    android:layout_width="wrap_content"
    android:layout_height="wrap_content"
    android:layout_alignRight="@id/entry"
    android:layout_alignEnd="@id/entry"
    android:layout_below="@id/entry"
    android:text="@string/ok"/>

  <Button
    android:id="@+id/cancel"
    android:layout_width="wrap_content"
    android:layout_height="wrap_content"
    android:layout_alignTop="@id/ok"
    android:layout_toLeftOf="@id/ok"
    android:text="@string/cancel"/>

</RelativeLayout>
```

(from Containers/Sampler/app/src/main/res/layout/url_dialog_rl.xml)

All the `RelativeLayout` itself needs is its size, set the same as with `vertical LinearLayout` in the earlier version of this sample — a width of `match_parent` and a height of `wrap_content`.

Other than `android:layout_width` and `android:layout_height`, all of the widget attributes with `layout_` are rules used by children of a `RelativeLayout` for positioning. So, we have:

Widget	Horizontal Anchor	Vertical Anchor
`TextView`	left/start side of the `RelativeLayout`, with `4dp` of margin	baseline of the `EditText`
`EditText`	right/end side of the `TextView`	top of the `RelativeLayout`
“OK” `Button`	right/end edge of the `EditText`	bottom of the `EditText`

Widget	Horizontal Anchor	Vertical Anchor
"Cancel" `Button`	left/start edge of the "OK" `Button`	top of the "OK" `Button`

Since the `EditText` width is set to `match_parent`, it will fill all the space in the "row" after the `TextView`. Since the "OK" `Button` horizontal position is tied to the `EditText`, the `Button` slides over to the edge of the screen, dragging along the connected "Cancel" `Button`.

As a result, we get the same basic UI:

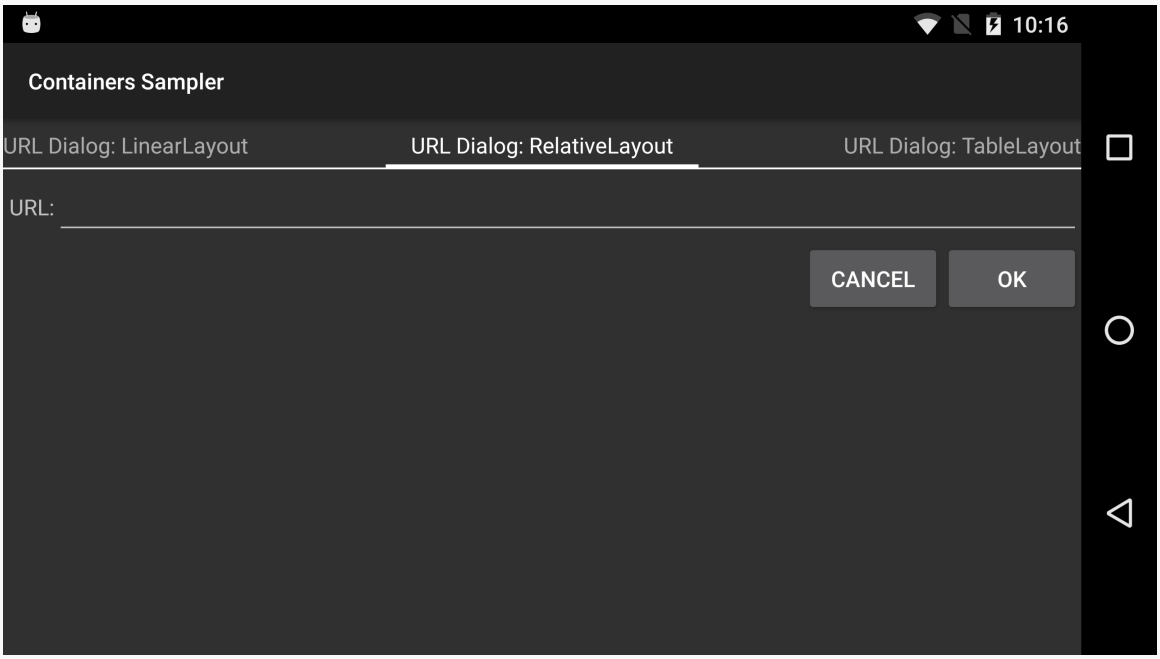

Figure 134: URL-Dialog Layout, Using RelativeLayout

Example: Overlap

`RelativeLayout` also has a feature that `LinearLayout` lacks — the ability to have widgets overlap one another. Later children of a `RelativeLayout` are "higher in the Z axis" than are earlier children, meaning that later children will overlap earlier children if they are set up to occupy the same space in the layout.

Here, we have two buttons, where the "I am small" button overlaps the "I am big" button:

Figure 135: Overlap Layout, Using RelativeLayout

The layout is fairly simple:

```
<?xml version="1.0" encoding="utf-8"?>
<RelativeLayout xmlns:android="http://schemas.android.com/apk/res/android"
  android:layout_width="match_parent"
  android:layout_height="match_parent">

  <Button
    android:layout_width="match_parent"
    android:layout_height="match_parent"
    android:text="@string/big"
    android:textSize="120dip"
    android:textStyle="bold"/>

  <Button
    android:layout_width="wrap_content"
    android:layout_height="wrap_content"
    android:layout_centerInParent="true"
    android:text="@string/small"/>

</RelativeLayout>
```

(from Containers/Sampler/app/src/main/res/layout/overlap_rl.xml)

The first `Button` is set to fill the screen. The second `Button` is set to be centered inside the parent, but only take up as much space as is needed for its caption. Hence, the second `Button` will appear to "float" over the first `Button`.

Both `Button` widgets can still be clicked, though clicking on the smaller `Button` does not also click the bigger `Button`. Your clicks will be handled by the widget on top in the case of an overlap like this.

On Android 5.0 and higher, it is possible to achieve a similar effect with `LinearLayout` by using the `android:elevation` attribute to control the Z axis, where higher elevation values mean higher on the Z axis, floating over those that are lower on the Z axis.

Tabula Rasa

If you like HTML tables, you will like Android's `TableLayout`. It allows you to position your widgets in a grid to your specifications. You control the number of rows and columns, which columns might shrink or stretch to accommodate their contents, and so on.

`TableLayout` works in conjunction with `TableRow`. `TableLayout` controls the overall behavior of the container, with the widgets themselves poured into one or more `TableRow` containers, one per row in the grid.

Concepts and Attributes

For all this to work, we need to figure out how widgets work with rows and columns, plus how to handle widgets that live outside of rows.

Putting Cells in Rows

Rows are declared by you, the developer, by putting widgets as children of a `TableRow` inside the overall `TableLayout`. You, therefore, control directly how many rows appear in the table.

The number of columns are determined by Android; you control the number of columns in an indirect fashion.

First, there will be at least one column per widget in your longest row. So if you have three rows, one with two widgets, one with three widgets, and one with four widgets, there will be at least four columns.

However, a widget can take up more than one column by including the `android:layout_span` property, indicating the number of columns the widget spans. This is akin to the `colspan` attribute one finds in table cells in HTML:

```
<TableRow>
  <TextView android:text="URL:" />
  <EditText
    android:id="@+id/entry"
    android:layout_span="3"/>
</TableRow>
```

In the above XML layout fragment, the field spans three columns.

Ordinarily, widgets are put into the first available column. In the above fragment, the label would go in the first column (column `0`, as columns are counted starting from `0`), and the field would go into a spanned set of three columns (columns `1` through `3`). However, you can put a widget into a different column via the `android:layout_column` property, specifying the `0`-based column the widget belongs to:

```
<TableRow>
  <Button
    android:id="@+id/cancel"
    android:layout_column="2"
    android:text="Cancel" />
  <Button android:id="@+id/ok" android:text="OK" />
</TableRow>
```

In the preceding XML layout fragment, the Cancel button goes in the third column (column `2`). The OK button then goes into the next available column, which is the fourth column.

Non-Row Children of TableLayout

Normally, `TableLayout` contains only `TableRow` elements as immediate children. However, it is possible to put other widgets in between rows. For those widgets, `TableLayout` behaves a bit like `LinearLayout` with vertical orientation. The widgets automatically have their width set to `match_parent`, so they will fill the same space that the longest row does.

Stretch, Shrink, and Collapse

By default, each column will be sized according to the "natural" size of the widest widget in that column (taking spanned columns into account). Sometimes, though, that does not work out very well, and you need more control over column behavior.

You can place an `android:stretchColumns` property on the `TableLayout`. This lists the column or columns that should absorb any extra space on the row, if the natural width of the columns collectively is narrower than the available horizontal space. You can:

- List a single column to be stretched (e.g., `android:stretchColumns="0"` to stretch the first column)
- Provide a comma-delimited list of columns to be stretched (e.g., `android:stretchColumns="0,1"` to stretch the first two columns)
- Use `*` to indicate that all columns should be stretched, akin to using equal `android:layout_weight` values in a horizontal `LinearLayout` (e.g., `android:stretchColumns="*"`)

Conversely, you can place an `android:shrinkColumns` property on the `TableLayout`. Again, this should be a single column number, a comma-delimited list of column numbers, or `*` as shorthand for referring to all columns. The columns listed in this property will try to word-wrap their contents to reduce the effective width of the column — by default, widgets are not word-wrapped. This helps if you have columns with potentially wordy content that might cause some columns to be pushed off the right side of the screen.

You can also leverage an `android:collapseColumns` property on the `TableLayout`, again with a column number or comma-delimited list of column numbers (`*` is not documented as an available option). These columns will start out "collapsed", meaning they will be part of the table information but will be invisible. Programmatically, you can collapse and un-collapse columns by calling `setColumnCollapsed()` on the `TableLayout`. You might use this to allow users to control which columns are of importance to them and should be shown versus which ones are less important and can be hidden.

You can also control stretching and shrinking at runtime via `setColumnStretchable()` and `setColumnShrinkable()`.

Android Studio Graphical Layout Editor

You will find `TableLayout` and `TableRow` in the "Layouts" section of the Palette in the Android Studio graphical layout editor:

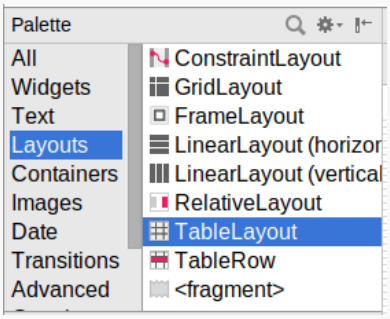

Figure 136: Layouts Section of Palette, TableLayout Highlighted

Given a `TableLayout`, you can drag one or more `TableRow` containers into it, then start dragging widgets into the rows, much as you might set up nested `LinearLayout` containers.

Example: A Bigger Form

One area where `TableLayout` excels is with forms, particularly if you are using the classic two-column "label and widget" structure for the form. This is because `TableLayout` can give you real columns, whereas `LinearLayout` and `RelativeLayout` cannot.

As with most `TableLayout` usages, the immediate children of ours are mostly `TableRow` containers, each providing the contents for the columns:

```
<?xml version="1.0" encoding="utf-8"?>
<TableLayout xmlns:android="http://schemas.android.com/apk/res/android"
  android:layout_width="match_parent"
  android:layout_height="match_parent"
  android:padding="8dp"
  android:stretchColumns="1">

  <TableRow>
    <TextView android:text="@string/name" />
    <EditText android:inputType="text" />
  </TableRow>

  <TableRow>
```

```
    <TextView android:text="@string/home_planet" />
    <EditText android:inputType="text" />
  </TableRow>

  <TableRow>
    <CheckBox
      android:layout_column="1"
      android:text="@string/android_programmer" />
  </TableRow>

  <TableRow>
    <TextView android:text="@string/favorite_food" />
    <EditText android:inputType="text" />
  </TableRow>

  <Button android:text="@string/do_something" />

</TableLayout>
```

(from Containers/Sampler/app/src/main/res/layout/form_tl.xml)

The `TableLayout` itself has `android:stretchColumns="1"`, so all leftover space in the rows will go to the second column (with the first column having an index of 0).

The first, second, and fourth `TableRow` each have the same structure, with a `TextView` label preceding the `EditText` where the user can fill in the data. The third `TableRow`, though, has only one child: the `CheckBox`. And, our `Button` lies outside of any `TableRow`, as a direct child of the root `TableLayout`. Both the `CheckBox` and the `Button` will exist on a row of their own. The difference is that the `CheckBox` goes in the second column, courtesy of `android:layout_column="1"`, whereas the `Button` will span the entire row (the way `TableRow` containers span the entire width of the `TableLayout`).

So, compared with the original `LinearLayout` version of this sample, our `TableLayout` columns are neat and aligned:

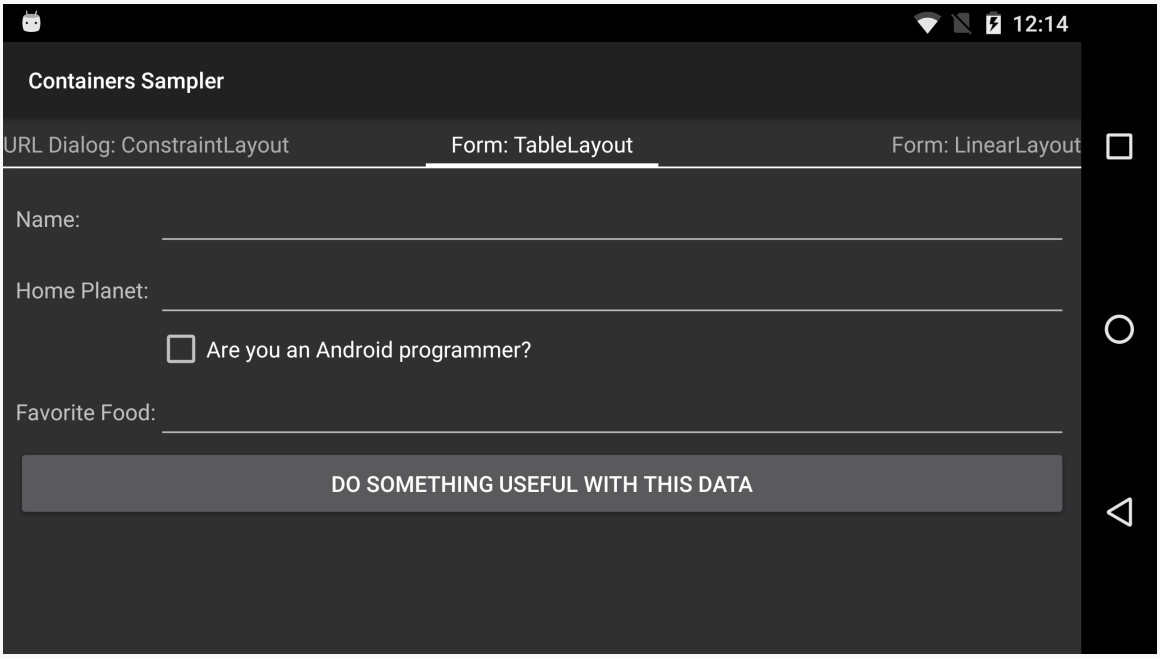

Figure 137: Form Layout, Using TableLayout

Example: URL Dialog

The "URL dialog" layout, previously seen implemented using `LinearLayout` and `RelativeLayout`, can also be implemented using a `TableLayout`. This is not the most natural use of a `TableLayout`, but you can do it if you wanted.

As with the form sample above, we start with a root `TableLayout` having `android:stretchColumns="1"` to give all extra space to the second column... even though we will wind up with a total of four columns this time:

```
<?xml version="1.0" encoding="utf-8"?>
<TableLayout xmlns:android="http://schemas.android.com/apk/res/android"
  android:layout_width="match_parent"
  android:layout_height="wrap_content"
  android:stretchColumns="1">

  <TableRow>

    <TextView
      android:layout_marginLeft="4dip"
      android:layout_marginStart="4dip"
      android:text="@string/url" />
```

```
    <EditText
      android:id="@+id/entry"
      android:layout_span="3"
      android:inputType="text" />
  </TableRow>

  <TableRow>

    <Button
      android:id="@+id/cancel"
      android:layout_column="2"
      android:text="@string/cancel" />

    <Button
      android:id="@+id/ok"
      android:text="@string/ok" />
  </TableRow>

</TableLayout>
```

(from Containers/Sampler/app/src/main/res/layout/url_dialog_tl.xml)

The `EditText` in the first `TableRow` has `android:layout_span="3"`, indicating that it should span to fill three columns. That, plus our one `TextView`, means that the first row is set up for four columns in total.

The first `Button` in the second `TableRow` has `android:layout_column="2"`, indicating that it should go into the third column. The other `Button` will go into the next column (the fourth column in this case), and the first two columns are skipped. So, this row also is set up for four columns.

So, when `android:stretchColumns="1"` is applied, the extra space will be given to the "contents" of the second column:

- the `EditText` in the first row
- the empty space preceding the two `Button` widgets in the second row

Hey, What About ConstraintLayout?

In 2016, Google introduced `ConstraintLayout`, with a vision of it becoming the fourth major container and perhaps the default one that you would choose. `ConstraintLayout` has its benefits, to be certain. However, it requires the use of a library, and we have not yet covered how to attach libraries to an Android module.

So, we will discuss `ConstraintLayout` a bit later in the book.

Turning Back to RTL

In order for the "start"/"end" attributes to work, you need to have `android:supportsRtl="true"` in your `<application>` element in your manifest. Most newly-created projects will have this attribute already set for you by the new-project wizard.

To see how your app behaves with RTL — without having to learn Arabic or Hebrew, if you are not literate in those languages — you can force Android to use RTL layout rules with any language on Android 4.2+ devices. To do this, go into the Settings app of the device or emulator and choose "Developer options". In there, scroll down to the "Force RTL layout direction" item. By default, this is turned off, and so layout direction is determined by the user's chosen language:

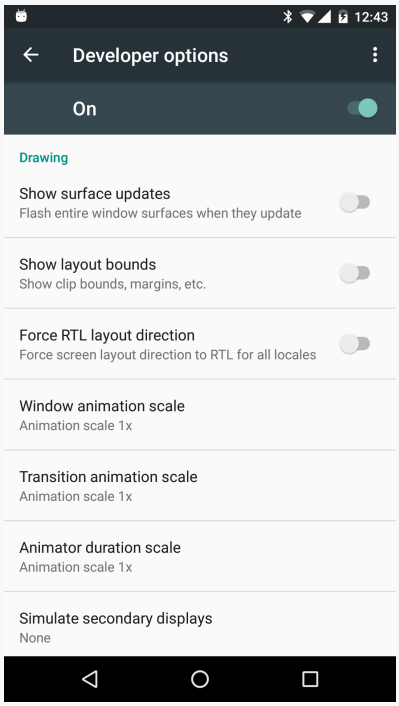

Figure 138: Developer Options in Settings, Normal Mode

Tapping that switch uses RTL layout rules — with "start" referring to the right and "end" referring to the left — for all languages:

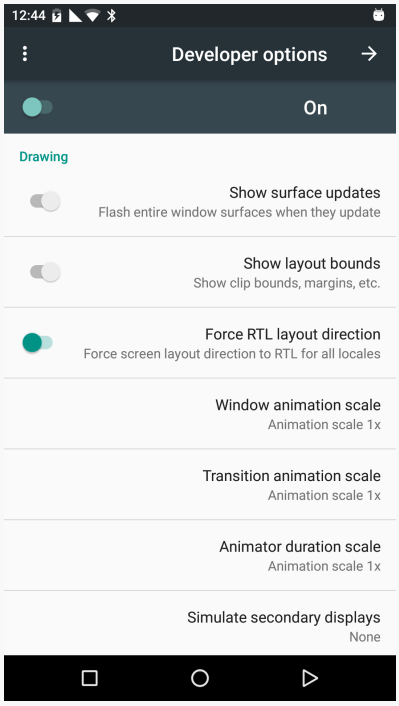

Figure 139: Developer Options in Settings, Forced-RTL Mode

As a reminder, if "Developer options" is not in the list of Settings categories, go into the "About device" category, find the build number item, and tap on it seven times. This will enable "Developer options" back on the main list of Settings categories.

Other Common Widgets and Containers

In the chapter on basic widgets, we left out all of the classic "two-state" widgets, such as checkboxes and radio buttons. We will examine those and other related widgets in this chapter.

Beyond the classic general-purpose containers (`LinearLayout`, `RelativeLayout`, `TableLayout`), there are other specialized containers, like `FrameLayout` and `RadioGroup`, that you will use from time to time. We will examine those in this chapter as well.

Just a Box to Check

The classic checkbox has two states: checked and unchecked. Clicking the checkbox toggles between those states to indicate a choice (e.g., "Add rush delivery to my order").

In Android, there is a `CheckBox` widget to meet this need. It has `TextView` as an ancestor, so you can use `TextView` properties like `android:textColor` to format the widget.

Within Java, you can invoke:

1. `isChecked()` to determine if the checkbox has been checked
2. `setChecked()` to force the checkbox into a checked or unchecked state
3. `toggle()` to toggle the checkbox as if the user clicked upon it

Also, you can register a listener object (in this case, an instance of `OnCheckedChangeListener`) to be notified when the state of the checkbox changes.

For example, from the `Basic/CheckBox` sample project, here is a simple checkbox layout:

```
<?xml version="1.0" encoding="utf-8"?>
<CheckBox xmlns:android="http://schemas.android.com/apk/res/android"
  android:id="@+id/check"
  android:layout_width="wrap_content"
  android:layout_height="wrap_content"
  android:text="@string/unchecked"/>
```

(from Basic/CheckBox/app/src/main/res/layout/main.xml)

The corresponding `CheckBoxDemo.java` retrieves and configures the behavior of the checkbox:

```
package com.commonsware.android.checkbox;

import android.app.Activity;
import android.os.Bundle;
import android.widget.CheckBox;
import android.widget.CompoundButton;

public class CheckBoxDemo extends Activity implements
    CompoundButton.OnCheckedChangeListener {
  CheckBox cb;

  @Override
  public void onCreate(Bundle state) {
    super.onCreate(state);
    setContentView(R.layout.main);

    cb=(CheckBox)findViewById(R.id.check);
    cb.setOnCheckedChangeListener(this);
  }

  public void onCheckedChanged(CompoundButton buttonView,
                               boolean isChecked) {
    if (isChecked) {
      cb.setText(R.string.checked);
    }
    else {
      cb.setText(R.string.unchecked);
    }
```

```
  }
}
```

(from Basic/CheckBox/app/src/main/java/com/commonsware/android/checkbox/CheckBoxDemo.java)

Note that the activity serves as its own listener for checkbox state changes since it implements the `OnCheckedChangeListener` interface (set via `cb.setOnCheckedChangeListener(this)`). The callback for the listener is `onCheckedChanged()`, which receives the checkbox whose state has changed and what the new state is. In this case, we update the text of the checkbox to reflect what the actual box contains.

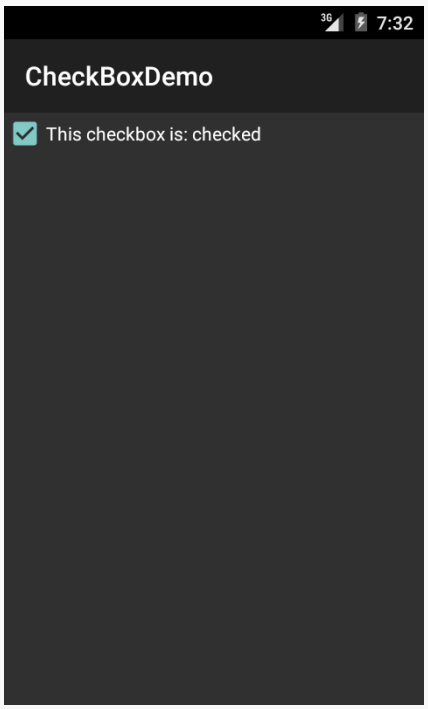

Figure 140: CheckBoxDemo Sample App, with CheckBox Checked

Android Studio Graphical Layout Editor

The `CheckBox` widget can be found in the "Widgets" portion of the Palette in the Android Studio Graphical Layout editor:

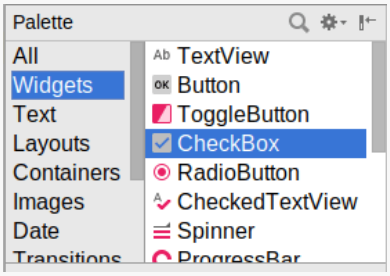

Figure 141: Widgets Palette, CheckBox Shown Highlighted

You can drag it into the layout and configure it as desired using the Attributes pane. As `CheckBox` inherits from `TextView`, most of the settings are the same as those you would find on a regular `TextView`.

Don't Like Checkboxes? How About Toggles or Switches?

A similar widget to `CheckBox` is `ToggleButton`. Like `CheckBox`, `ToggleButton` is a two-state widget that is either checked or unchecked. However, `ToggleButton` has a distinct visual appearance:

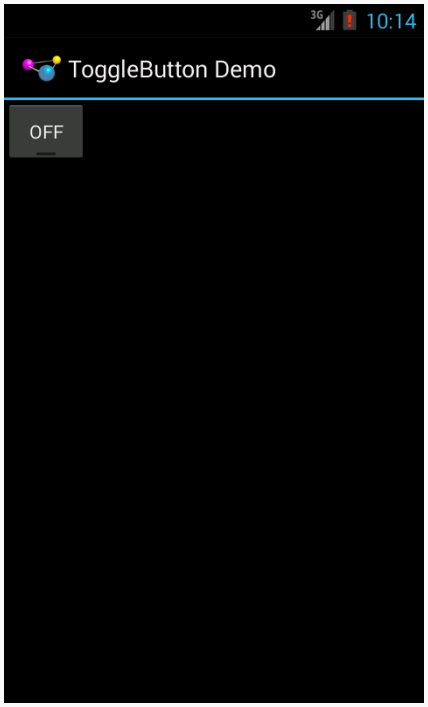

Figure 142: ToggleButtonDemo Sample, Unchecked

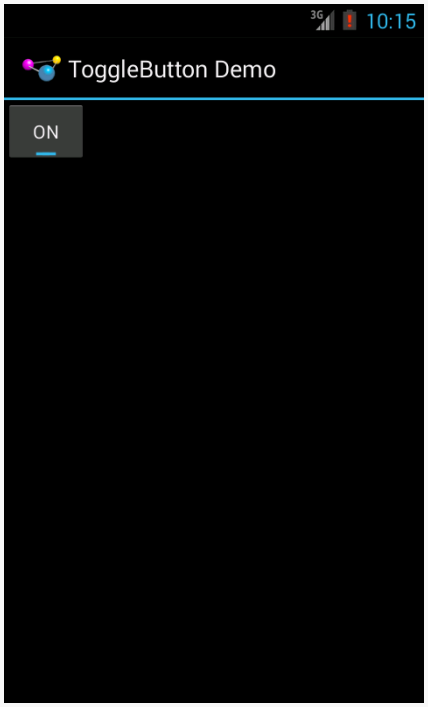

Figure 143: ToggleButtonDemo Sample, Checked

Otherwise, `ToggleButton` behaves much like `CheckBox`. You can put it in a layout file, as seen in the `Basic/ToggleButton` sample:

```
<?xml version="1.0" encoding="utf-8"?>
<ToggleButton xmlns:android="http://schemas.android.com/apk/res/android"
    android:id="@+id/toggle"
    android:layout_width="wrap_content"
    android:layout_height="wrap_content" />
```

(from Basic/ToggleButton/app/src/main/res/layout/main.xml)

You can also set up an `OnCheckedChangeListener` to be notified when the user changes the state of the `ToggleButton`.

Similarly, Android has a `Switch` widget, showing the state via a small "ON/OFF" slider:

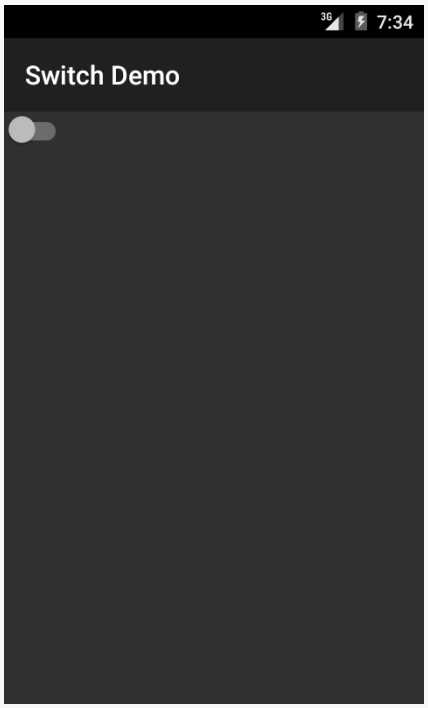

Figure 144: SwitchDemo Sample, Unchecked

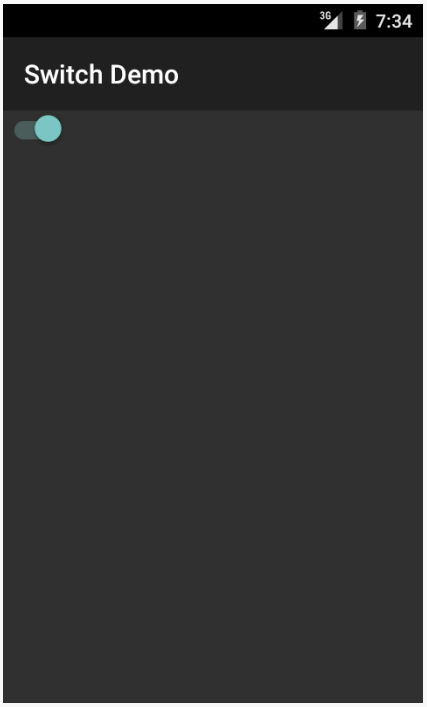

Figure 145: SwitchDemo Sample, Checked

`Switch`, like `CheckBox` and `ToggleButton`, inherits from `CompoundButton`, and therefore shares a common API, for methods like `toggle()`, `isChecked()`, and `setChecked()`. And, as with the others, you can put it in a layout file, as seen in the `Basic/Switch` sample:

```
<?xml version="1.0" encoding="utf-8"?>
<Switch xmlns:android="http://schemas.android.com/apk/res/android"
    android:id="@+id/toggle"
    android:layout_width="wrap_content"
    android:layout_height="wrap_content" />
```

(from Basic/Switch/app/src/main/res/layout/main.xml)

The biggest limitation with `Switch` is that it was only added to the Android SDK in API Level 14. If your `minSdkVersion` is set to 14 or higher, you are welcome to use `Switch`. If your `minSdkVersion` is set to something lower than 14, though, you will either need to choose something else or get into more complicated scenarios, like using a library that offers a backport of `Switch`. We will cover those more complicated scenarios later in the book; for now, it is simplest to only use `Switch` if your `minSdkVersion` is set to 14 or higher.

Android Studio Graphical Layout Editor

The `ToggleButton` and `Switch` widgets can be found in the "Widgets" portion of the Palette in the Android Studio Graphical Layout editor, just beneath the `CheckBox` widget:

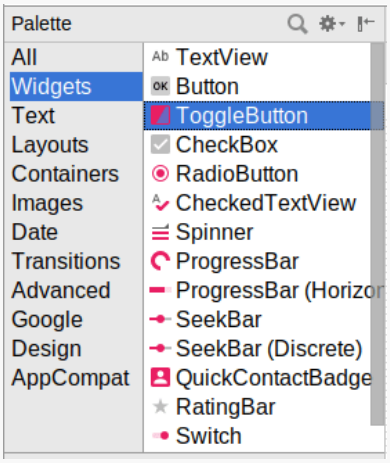

Figure 146: Widgets Palette, ToggleButton Highlighted and Switch At Bottom

You can drag either widget into the layout and configure it as desired using the Attributes pane.

Turn the Radio Up

As with other implementations of radio buttons in other toolkits, Android's radio buttons are two-state, like checkboxes, but can be grouped such that only one radio button in the group can be checked at any time.

`CheckBox`, `ToggleButton`, `Switch`, and `RadioButton` all inherit from `CompoundButton`, which in turn inherits from `TextView`. Hence, all the standard `TextView` properties for font face, style, color, etc. are available for controlling the look of radio buttons. Similarly, you can call `isChecked()` on a `RadioButton` to see if it is selected, `toggle()` to change its checked state, and so on, like you can with a `CheckBox`.

Most times, you will want to put your `RadioButton` widgets inside of a `RadioGroup`. The `RadioGroup` is a `LinearLayout` that indicates a set of radio buttons whose state is tied, meaning only one button out of the group can be selected at any time. If you assign an `android:id` to your `RadioGroup` in your XML layout, you can access the group from your Java code and invoke:

1. `check()` to check a specific radio button via its ID (e.g., `group.check(R.id.radio1)`)
2. `clearCheck()` to clear all radio buttons, so none in the group are checked
3. `getCheckedRadioButtonId()` to get the ID of the currently-checked radio button (or `-1` if none are checked)

Note that the mutual-exclusion feature of `RadioGroup` only applies to `RadioButton` widgets that are immediate children of the `RadioGroup`. You cannot have other containers between the `RadioGroup` and its `RadioButton` widgets.

For example, from the `Basic/RadioButton` sample application, here is an XML layout showing a `RadioGroup` wrapping a set of `RadioButton` widgets:

```
<?xml version="1.0" encoding="utf-8"?>
<RadioGroup
  xmlns:android="http://schemas.android.com/apk/res/android"
  android:orientation="vertical"
  android:layout_width="match_parent"
  android:layout_height="match_parent"
  >
    <RadioButton android:id="@+id/radio1"
      android:layout_width="wrap_content"
      android:layout_height="wrap_content"
      android:text="@string/rock" />

    <RadioButton android:id="@+id/radio2"
      android:layout_width="wrap_content"
      android:layout_height="wrap_content"
      android:text="@string/scissors" />

    <RadioButton android:id="@+id/radio3"
      android:layout_width="wrap_content"
      android:layout_height="wrap_content"
      android:text="@string/paper" />
</RadioGroup>
```

(from Basic/RadioButton/app/src/main/res/layout/main.xml)

Using the stock Android-generated Java for the project and this layout, you get:

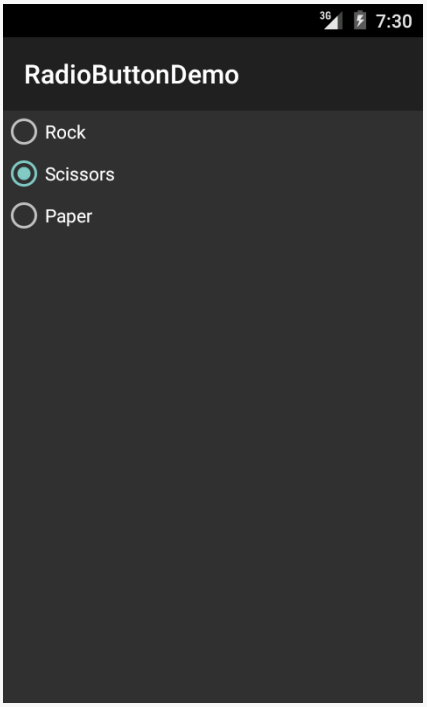

Figure 147: RadioButtonDemo, with "Scissors" Checked

Note that the radio button group is initially set to be completely unchecked at the outset. To preset one of the radio buttons to be checked, use either `setChecked()` on the `RadioButton` or `check()` on the `RadioGroup` from within your `onCreate()` callback in your activity. Alternatively, you can use the `android:checked` attribute on one of the `RadioButton` widgets in the layout file.

Android Studio Graphical Layout Editor

The `RadioGroup` container can be found in the "Containers" portion of the Palette in the Android Studio Graphical Layout editor:

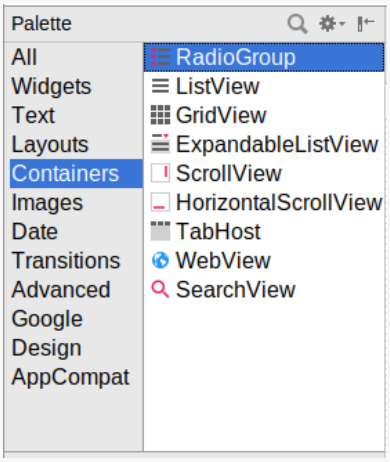

Figure 148: Widgets Palette, RadioGroup Highlighted

Dragging a `RadioGroup` into the preview works much like dragging a `LinearLayout` into the preview. You get a box into which you can drag other widgets, such as the `RadioButton` found in the "Widgets" section of the Palette.

Scrollwork

Phone screens tend to be small, which requires developers to use some tricks to present a lot of information in the limited available space. One trick for doing this is to use scrolling, so only part of the information is visible at one time, the rest available via scrolling up or down.

`ScrollView` is a container that provides scrolling for its contents. You can take a layout that might be too big for some screens, wrap it in a `ScrollView`, and still use your existing layout logic. It just so happens that the user can only see part of your layout at one time, the rest available via scrolling.

For example, here is a `ScrollView` used in an XML layout file (from the `Containers/Scroll` demo):

```
<?xml version="1.0" encoding="utf-8"?>
<ScrollView
  xmlns:android="http://schemas.android.com/apk/res/android"
  android:layout_width="match_parent"
  android:layout_height="wrap_content">
  <TableLayout
    android:layout_width="match_parent"
    android:layout_height="match_parent"
```

```
    android:stretchColumns="0">
    <TableRow>
      <View
        android:layout_height="80dip"
        android:background="#000000"/>
      <TextView android:text="#000000"
        android:paddingLeft="4dip"
        android:layout_gravity="center_vertical" />
    </TableRow>
    <TableRow>
      <View
        android:layout_height="80dip"
        android:background="#440000" />
      <TextView android:text="#440000"
        android:paddingLeft="4dip"
        android:layout_gravity="center_vertical" />
    </TableRow>
    <TableRow>
      <View
        android:layout_height="80dip"
        android:background="#884400" />
      <TextView android:text="#884400"
        android:paddingLeft="4dip"
        android:layout_gravity="center_vertical" />
    </TableRow>
    <TableRow>
      <View
        android:layout_height="80dip"
        android:background="#aa8844" />
      <TextView android:text="#aa8844"
        android:paddingLeft="4dip"
        android:layout_gravity="center_vertical" />
    </TableRow>
    <TableRow>
      <View
        android:layout_height="80dip"
        android:background="#ffaa88" />
      <TextView android:text="#ffaa88"
        android:paddingLeft="4dip"
        android:layout_gravity="center_vertical" />
    </TableRow>
    <TableRow>
      <View
        android:layout_height="80dip"
        android:background="#ffffaa" />
      <TextView android:text="#ffffaa"
        android:paddingLeft="4dip"
        android:layout_gravity="center_vertical" />
```

```
    </TableRow>
    <TableRow>
      <View
        android:layout_height="80dip"
        android:background="#ffffff" />
      <TextView android:text="#ffffff"
        android:paddingLeft="4dip"
        android:layout_gravity="center_vertical" />
    </TableRow>
  </TableLayout>
</ScrollView>
```

(from Containers/Scroll/app/src/main/res/layout/main.xml)

Without the `ScrollView`, the table would take up at least 560 density-independent pixels (7 rows at 80 dips each, based on the `View` declarations). There may be some devices with screens capable of showing that much information, but many will be smaller. The `ScrollView` lets us keep the table as-is, but only present part of it at a time.

On the stock Android emulator, when the activity is first viewed, you see:

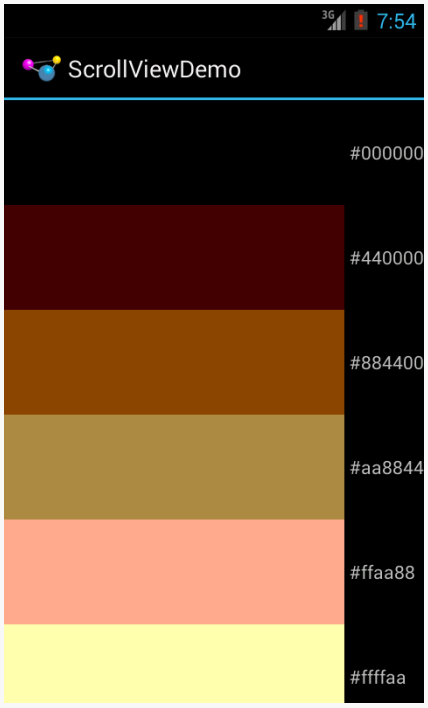

Figure 149: The ScrollViewDemo sample application

Notice how only five rows and part of the sixth are visible. You can scroll up and down to see the remaining rows. Also note how the right side of the content gets clipped by the scrollbar — be sure to put some padding on that side or otherwise ensure your own content does not get clipped in that fashion.

Android also has `HorizontalScrollView`, which works like `ScrollView`... just horizontally. This would be good for forms that might be too wide rather than too tall. Note that `ScrollView` only scrolls vertically and `HorizontalScrollView` only scrolls horizontally.

Also, note that you cannot put scrollable items into a `ScrollView`. For example, a `ListView` widget — which we will see in an upcoming chapter — already knows how to scroll. You do not need to put a `ListView` in a `ScrollView`, and if you were to try, it would not work very well.

And, a `ScrollView` or `HorizontalScrollView` can only have one child — if you want more than one, wrap the children in a suitable container class (e.g., a `LinearLayout`) and put that inside the `ScrollView` or `HorizontalScrollView`.

Android Studio Graphical Layout Editor

The `ScrollView` and `HorizontalScrollView` widgets appear in the "Containers" section of the Palette in the Graphical Layout editor. You can drag one of these into your layout XML resource, then drag *one* child into it.

Making Progress with ProgressBars

If you are going to fork background threads to do work on behalf of the user, you will want to think about keeping the user informed that work is going on. This is particularly true if the user is effectively waiting for that background work to complete.

The typical approach to keeping users informed of progress is some form of progress bar, like you see when you copy a bunch of files from place to place in many desktop operating systems. Android supports this through the `ProgressBar` widget.

A `ProgressBar` keeps track of progress, defined as an integer, with `0` indicating no progress has been made. You can define the maximum end of the range — what value indicates progress is complete — via `setMax()`. By default, a `ProgressBar` starts with a progress of `0`, though you can start from some other position via

`setProgress()`. Android 8.0 adds `setMin()` and `android:min` to set the lower end of the range to a custom value, instead of the default of `0`.

If you prefer your progress bar to be indeterminate — meaning that it will show a general animated effect, rather than a specific amount of progress – use `setIndeterminate()`, setting it to `true`.

In your Java code, you can either positively set the amount of progress that has been made (via `setProgress()`) or increment the progress from its current amount (via `incrementProgressBy()`). You can find out how much progress has been made via `getProgress()`.

Framing the Scene

Android has a `FrameLayout` class. Like `LinearLayout`, `RelativeLayout`, and `TableLayout`, `FrameLayout` exists to size and position its children. However, `FrameLayout` has a very simple pair of layout rules:

1. All children go in the upper-start corner (e.g., upper-left for LTR languages), unless `android:gravity` indicates to position the children elsewhere
2. Later children are higher on the Z axis than are earlier children, as with `RelativeLayout`, so children can overlap

The result is that all the widgets are stacked one on top of another.

This may seem useless. And, truth be told, it is not used nearly as commonly as are other containers.

Primarily, `FrameLayout` is used in places where we want to reserve space for something, but we do not know what the "something" is at compile time. The decision of what the "something" is will be made at runtime, where we will use Java code to put something in the `FrameLayout`. We will see this pattern used with fragments, later in the book.

Occasionally, `FrameLayout` is literally used for "framing", where we want some sort of a border around a child. In this case, the background of the `FrameLayout` (e.g., `android:background`) defines what the frame should look like. We will see this approach used in a few places, such as in the chapter on adding drag-and-drop to your app.

Visit the Trails!

The trails portion of the book contains a widget catalog, providing capsule descriptions and samples for a number of widgets not described elsewhere in this book.

You might also be interested in `GridLayout`, which is an alternative to the classic `LinearLayout`, `RelativeLayout`, and `TableLayout` containers.

Tutorial #5 - Creating a Layout

Later in these tutorials, we are going to allow the user to write down notes related to the book. These notes will be stored in a database and can be viewed, modified, or deleted as the user sees fit.

In this tutorial, we are going to set up the layout resource to allow the user to fill in these notes.

This is a continuation of the work we did in the previous tutorial.

You can find the results of the previous tutorial and the results of this tutorial in the book's GitHub repository.

Step #1: Creating a New Layout Resource

Right-click over the `res/layout/` directory and choose New > "Layout resource file" from the context menu. This brings up the New Layout Resource File dialog:

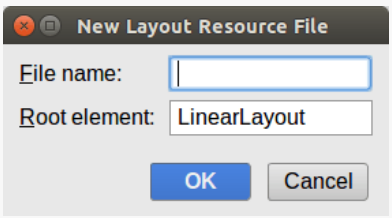

Figure 150: Android Studio New Layout Resource File Dialog

Fill in `editor` as the "Layout File Name", leave the rest of the dialog alone, and click the "OK" button.

Step #2: Defining the UI

That should have opened up the graphical layout editor for this new `editor` layout resource:

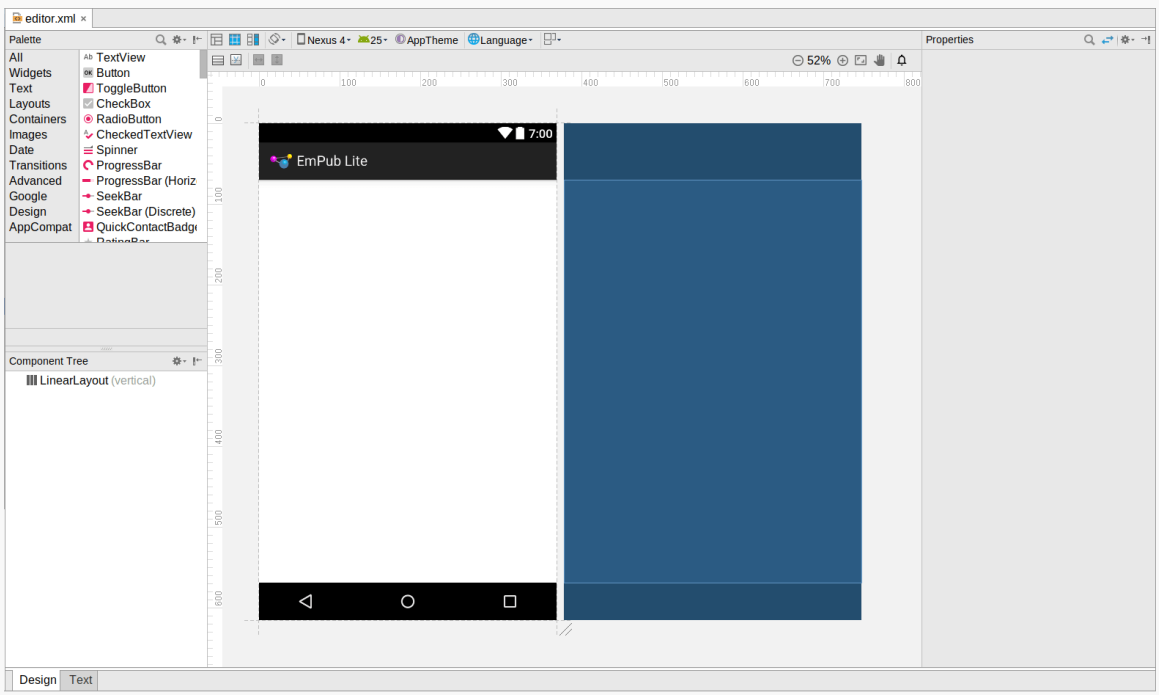

Figure 151: Graphical Layout Editor

Drag a "Multiline Text" widget from the Text section of the Palette into the preview area. In the attributes pane, change the `android:layout_width` and `android:layout_height` each to be `match_parent` and change the ID to `editor`:

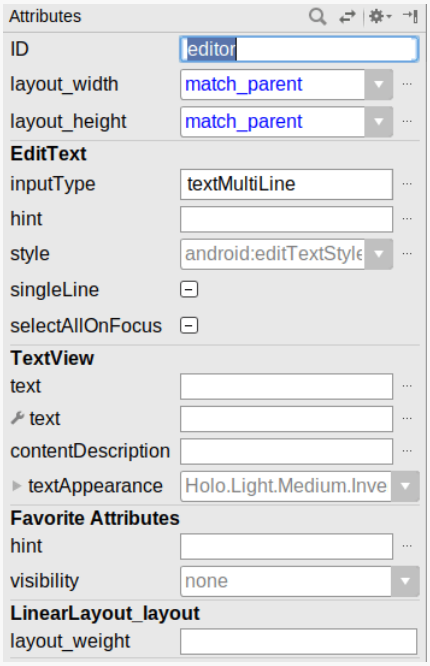

Figure 152: Graphical Layout Editor Attributes Pane

Next, in the attributes pane, click on the "hint" entry, then click the "..." button to the right of it. This will open up a string resource picker dialog:

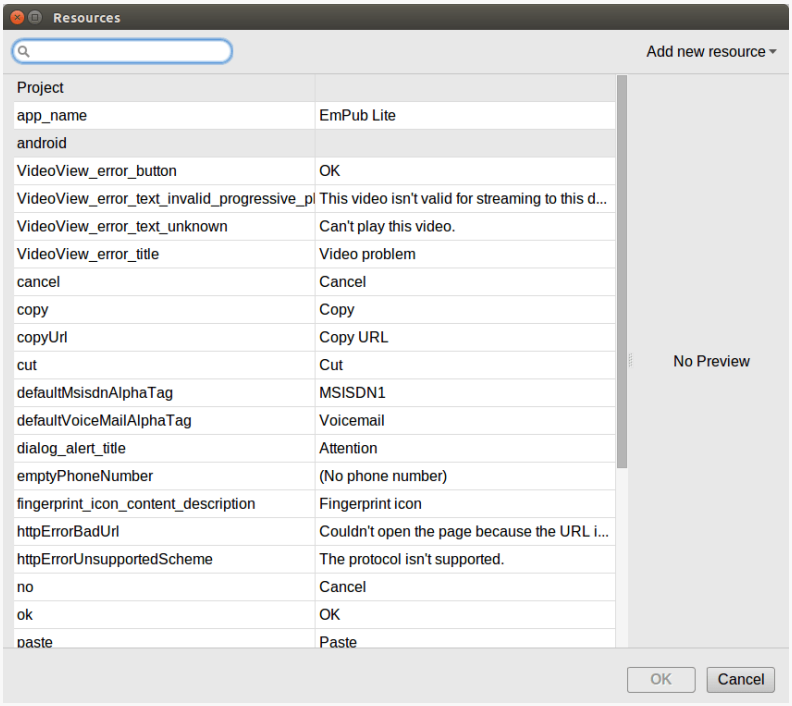

Figure 153: Android Studio String Resource Picker Dialog

Towards the upper right, click the "Add new resource" drop-down and choose "New string Value..." from it, to bring up the string resource editor dialog:

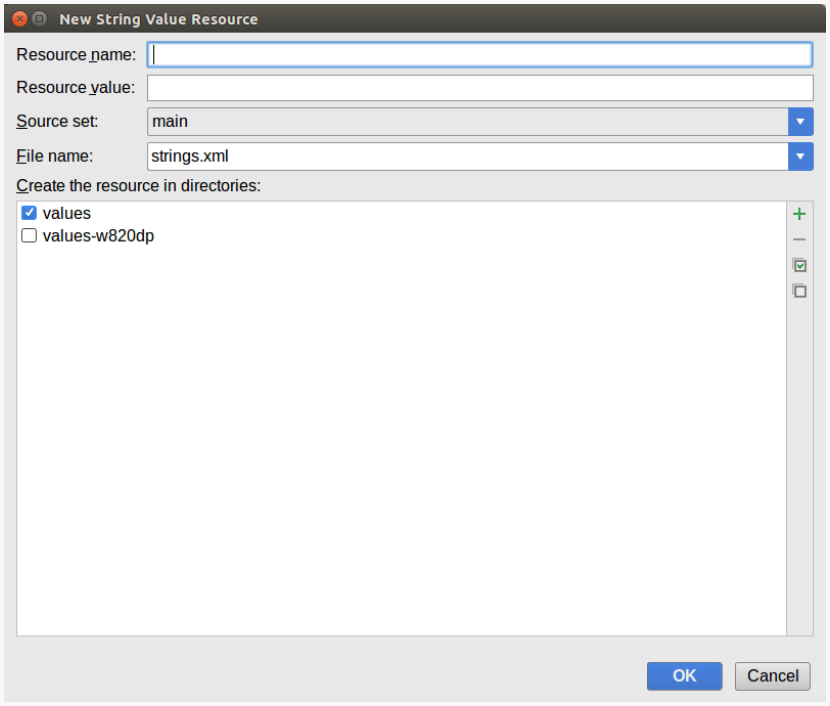

Figure 154: Android Studio New String Resource Dialog

Fill in a resource name of `hint` and a value of `Enter notes here`. Leave the rest of the dialog alone, and click OK.

Then, back in the attributes pane, switch to viewing all of the attributes, rather than just the subset. Scroll down to the `gravity` property, fold it open, and change the checked values to "top" and "start". In Android Studio 3.0, this will look bizarre, with four other checkmarks appearing, due to a bug in the IDE.

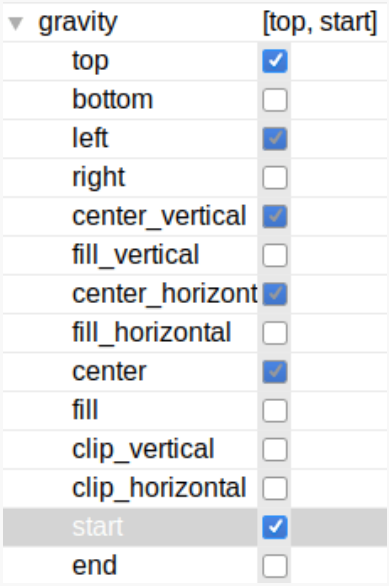

Figure 155: Layout Editor Attributes Pane, Showing Gravity Options

If you look at the layout XML in the Text sub-tab, you should have something like this:

```
<?xml version="1.0" encoding="utf-8"?>
<LinearLayout
  xmlns:android="http://schemas.android.com/apk/res/android"
  android:orientation="vertical" android:layout_width="match_parent"
  android:layout_height="match_parent">

  <EditText
    android:layout_width="match_parent"
    android:layout_height="match_parent"
    android:inputType="textMultiLine"
    android:ems="10"
    android:id="@+id/editor"
    android:hint="@string/hint"
    android:gravity="top|start" />
</LinearLayout>
```

(from EmPubLite-AndroidStudio/T5-Layout/EmPubLite/app/src/main/res/layout/editor.xml)

Your hint may appear to be `"Enter notes here"`, as if you had directly typed that in rather than creating a string resource. As was covered earlier, Android Studio is lying to you. Click on the `"Enter notes here"` to see the actual string resource reference.

In Our Next Episode…

… we will attach a third-party library to our tutorial project.

GUI Building, Continued

If you are using an IDE, and you have been experimenting with the graphical layout editor and drag-and-drop GUI building, this chapter will cover some other general features of this editor that you may find useful.

Even if you are not using an IDE, you may want to at least skim this chapter, as you will find a few tricks that will be relevant for you as well.

Making Your Selection

Clicking on a widget makes it the selected widget, meaning that the toolbar buttons will affect that widget (or, sometimes, its container, depending upon the button). Selected widgets have a thin blue border with blue square "grab handles" for adjusting its size and position.

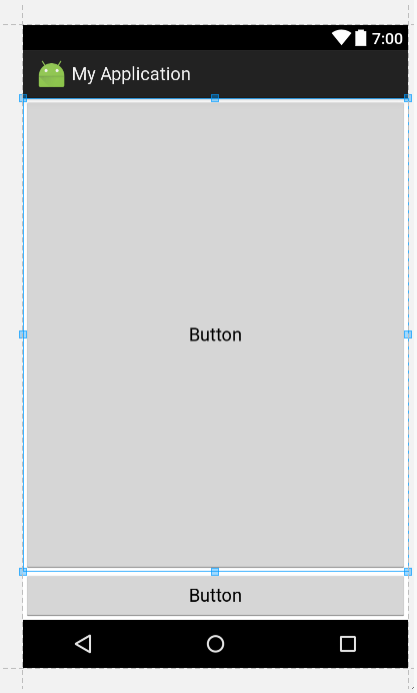

Figure 156: Android Studio, Selected Widget in Graphical Layout Editor

Clicking on a container also selects it. However, there may or may not be a blue border — in particular, containers that fill the screen (`match_parent` for width and height) do not seem to get the border.

Sometimes, though, you want to select a container that you cannot reach, because its contents are completely filled with widgets. In these cases, click on the widget or container in the Component Tree pane to select it.

Including Includes

Sometimes, you have a widget or a collection of widgets that you want to reuse across multiple layout XML resources. Android supports the notion of an "include" that allows this. Simply create a dedicated layout XML resource that contains the widget(s) to reuse, then add them to your main layouts via an `<include>` element:

```
<include layout="@layout/thing_we_are_reusing" />
```

You can even assign the `<include>` element a width or height if needed, as if it were just a widget or container.

The IDE used to make it easy for you to take widgets from an existing layout XML resource and extract them into a separate layout XML resource, replacing them with an `<include>` element. Multi-select the widgets in the blueprint or design views, or in the Preview tool when on the Text sub-tab of the layout editor. Then, right-click and choose

Refactor > Extract Layout from the context menu. This will display a dialog where you can fill in the file name of your resulting resource:

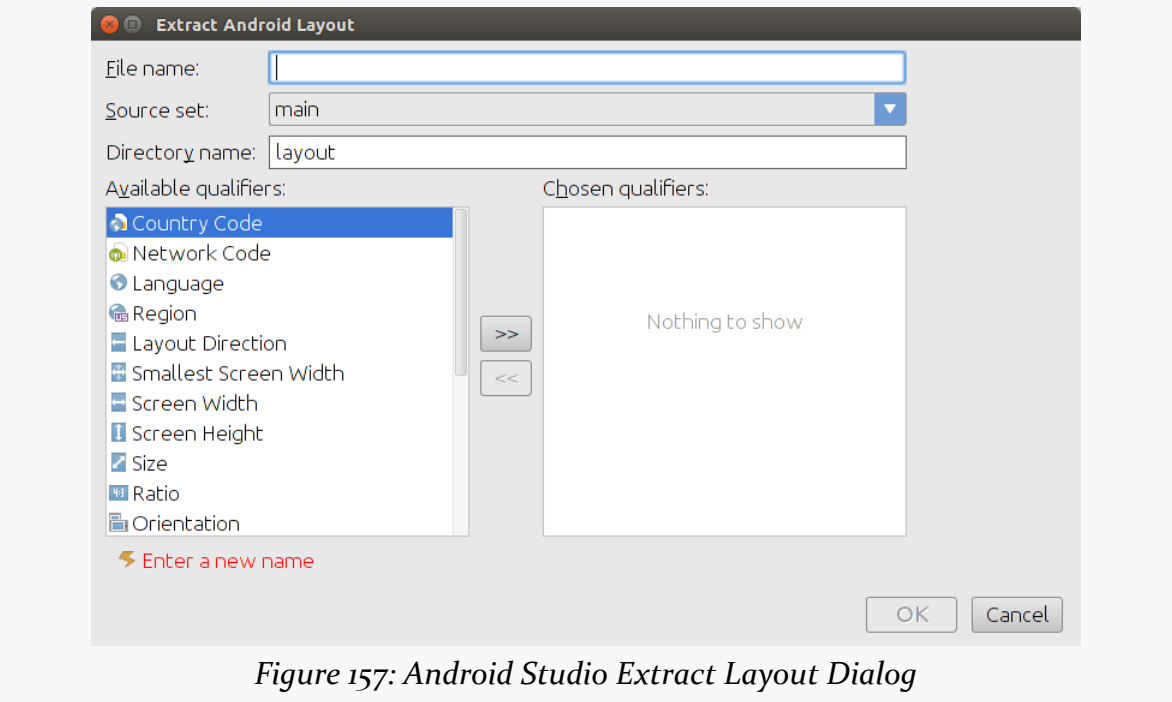

Figure 157: Android Studio Extract Layout Dialog

If you are extracting multiple widgets that are not wrapped in their own container, the IDE will automatically wrap them in a `<merge>` element:

```
<?xml version="1.0" encoding="utf-8"?>
<merge xmlns:android="http://schemas.android.com/apk/res/android">
  <!-- widgets go here -->
</merge>
```

This is necessary purely from an XML standpoint — you cannot have multiple root elements in an XML file. When the `<merge>` is added to another layout via `<include>`, the `<merge>` element itself evaporates, leaving behind its children.

NOte that there is a bug that prevents this feature from working if you multi-select the widgets in the Component Tree.

Preview of Coming Attractions

At the top of the graphical layout editor, you will find a series of drop-downs that allow you to tailor what the preview looks like:

Figure 158: Android Studio Preview Controls

Your IDE will choose some likely defaults based upon your project settings, but you are welcome to change them as you see fit. Notable changes include:

- What version of Android is used for the preview (as widget styling changes from time to time in Android releases)
- What language is used for your string resources?
- What size and resolution of screen is used?
- Is it displayed in portrait or landscape?

These only affect the preview, so they show you (approximately) what your layout will look like under those conditions, but they do not modify anything about your layout XML itself.

AdapterViews and Adapters

If you want the user to choose something out of a collection of somethings, you could use a bunch of `RadioButton` widgets. However, Android has a series of more flexible widgets than that, ones that this book will refer to as "selection widgets".

These include:

- `ListView`, which is your typical "list box"
- `Spinner`, which (more or less) is a drop-down list
- `GridView`, offering a two-dimensional roster of choices
- `ExpandableListView`, a limited "tree" widget, supporting two levels in the hierarchy

and many more.

At their core, these are ordinary widgets. You will find them in your tool palette of your IDE's graphical layout editor, and can drag them and position them as you see fit.

The key is that these all have a common superclass: `AdapterView`, so named because they partner with objects implementing the `Adapter` interface to determine what choices are available for the user to choose from.

Adapting to the Circumstances

An `Adapter` is your bridge between your model data and that data's visual representation in the `AdapterView`:

- an `Adapter` might "adapt" an `Invoice` into a `View` that would serve as a row in a `ListView`
- an `Adapter` might "adapt" a `Book` into a `View` that would serve as a cell in a `GridView`
- and so on

Android ships with several `Adapter` classes ready for your use, where the different adapter classes are designed to "adapt" different sorts of collections (e.g., arrays versus results of database queries). Android also has a `BaseAdapter` class that can serve as the foundation for your own `Adapter` implementation, if you need to "adapt" a collection of data that does not fit any of the `Adapter` classes supplied by Android.

Using ArrayAdapter

The easiest adapter to use is `ArrayAdapter` — all you need to do is wrap one of these around a Java array or `java.util.List` instance, and you have a fully-functioning adapter:

```
String[] items={"this", "is", "a", "really", "silly", "list"};
new ArrayAdapter<String>(this,
                         android.R.layout.simple_list_item_1,
                         items);
```

One flavor of the `ArrayAdapter` constructor takes three parameters:

1. The `Context` to use (typically this will be your activity instance)
2. The resource ID of a view to use (such as a built-in system resource ID, as shown above)
3. The actual array or list of items to show

By default, the `ArrayAdapter` will invoke `toString()` on the objects in the list and wrap each of those strings in the view designated by the supplied resource. `android.R.layout.simple_list_item_1` simply turns those strings into `TextView` objects. Those `TextView` widgets, in turn, will be shown in the list or spinner or whatever widget uses this `ArrayAdapter`. If you want to see what `android.R.layout.simple_list_item_1` looks like, you can find a copy of it in your SDK installation — just search for `simple_list_item_1.xml`.

We will see in a later section how to subclass an `Adapter` and override row creation, to give you greater control over how rows and cells appear.

Lists of Naughty and Nice

The classic listbox widget in Android is known as `ListView`. Include one of these in your layout, invoke `setAdapter()` to supply your data and child views, and attach a listener via `setOnItemSelectedListener()` to find out when the selection has changed. With that, you have a fully-functioning listbox.

However, if your activity is dominated by a single list, you might well consider creating your activity as a subclass of `ListActivity`, rather than the regular `Activity` base class. If your main view is just the list, you do not even need to supply a layout — `ListActivity` will construct a full-screen list for you. If you do want to customize the layout, you can, so long as you identify your `ListView` as `@android:id/list`, so `ListActivity` knows which widget is the main list for the activity.

For example, here is a layout pulled from the `Selection/List` sample project:

```
<?xml version="1.0" encoding="utf-8"?>
<LinearLayout
  xmlns:android="http://schemas.android.com/apk/res/android"
  android:orientation="vertical"
  android:layout_width="match_parent"
  android:layout_height="match_parent" >
  <TextView
    android:id="@+id/selection"
    android:layout_width="match_parent"
    android:layout_height="wrap_content"/>
  <ListView
    android:id="@android:id/list"
    android:layout_width="match_parent"
    android:layout_height="match_parent"
    />
</LinearLayout>
```

(from Selection/List/app/src/main/res/layout/main.xml)

It is just a list with a label on top to show the current selection.

The Java code to configure the list and connect the list with the label is:

```
package com.commonsware.android.list;

import android.app.ListActivity;
import android.os.Bundle;
```

```
import android.view.View;
import android.widget.ArrayAdapter;
import android.widget.ListView;
import android.widget.TextView;

public class ListViewDemo extends ListActivity {
  private TextView selection;
  private static final String[] items={"lorem", "ipsum", "dolor",
          "sit", "amet",
          "consectetuer", "adipiscing", "elit", "morbi", "vel",
          "ligula", "vitae", "arcu", "aliquet", "mollis",
          "etiam", "vel", "erat", "placerat", "ante",
          "porttitor", "sodales", "pellentesque", "augue", "purus"};

  @Override
  public void onCreate(Bundle state) {
    super.onCreate(state);
    setContentView(R.layout.main);
    setListAdapter(new ArrayAdapter<String>(this,
                       android.R.layout.simple_list_item_1,
                       items));
    selection=(TextView)findViewById(R.id.selection);
  }

  @Override
  public void onListItemClick(ListView parent, View v, int position,
                              long id) {
    selection.setText(items[position]);
  }
}
```

(from Selection/List/app/src/main/java/com/commonsware/android/list/ListViewDemo.java)

With `ListActivity`, you can set the list adapter via `setListAdapter()` — in this case, providing an `ArrayAdapter` wrapping an array of Latin strings. To find out when the list selection changes, override `onListItemClick()` and take appropriate steps based on the supplied child view and position (in this case, updating the label with the text for that position).

The results?

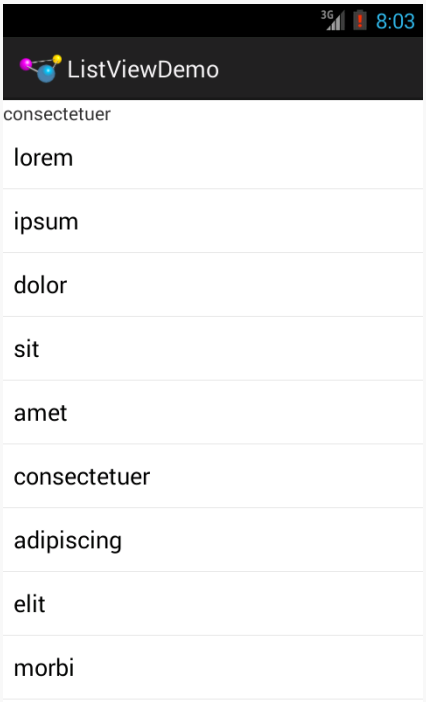

Figure 159: ListViewDemo, After User Taps on "consecteteur"

The second parameter to our `ArrayAdapter` — `android.R.layout.simple_list_item_1` — controls what the rows look like. The value used in the preceding example provides the standard Android list row: a big font with lots of padding to offer a large touch target for the user.

Clicks versus Selections

One thing that can confuse some Android developers is the distinction between clicks and selections. One might think that they are the same thing — after all, clicking on something selects it, right?

Well, no. At least, not in Android. At least not all of the time.

Android is designed to be used with touchscreen devices and non-touchscreen devices. Historically, Android has been dominated by devices that only offered touchscreens. However, there are various devices powered by Android and connected to TVs. Most TVs are not touchscreens, and so users of those TV-using Android devices will use some sort of remote control to drive Android. And some

Android devices offer both touchscreens and some other sort of pointing device — D-pad, trackball, arrow keys, etc.

To accommodate both styles of device, Android sometimes makes a distinction between selection events and click events. Widgets based on the "spinner" paradigm — including `Spinner` — treat everything as selection events. Other widgets — like `ListView` and `GridView` — treat selection events and click events differently. For these widgets, selection events are driven by the pointing device, such as using arrow keys to move a highlight bar up and down a list. Click events are when the user either "clicks" the pointing device (e.g., presses the center D-pad button) *or* taps on something in the widget using the touchscreen.

Choice Modes

By default, `ListView` is set up simply to collect clicks on list entries. Sometimes, though, you want a list that tracks a user's choice, or possibly multiple choices. `ListView` can handle that as well, but it requires a few changes.

First, you will need to call `setChoiceMode()` on the `ListView` in Java code to set the choice mode, classically supplying either `CHOICE_MODE_SINGLE` or `CHOICE_MODE_MULTIPLE` as the value. You can get your `ListView` from a `ListActivity` via `getListView()`. You can also declare this via the `android:choiceMode` attribute in your layout XML.

Then, rather than use `android.R.layout.simple_list_item_1` as the layout for the list rows in your `ArrayAdapter` constructor, you can use either `android.R.layout.simple_list_item_single_choice` or `android.R.layout.simple_list_item_multiple_choice` for single-choice or multiple-choice lists, respectively.

For example, here is an activity layout from the `Selection/Checklist` sample project:

```
<?xml version="1.0" encoding="utf-8"?>
<ListView
xmlns:android="http://schemas.android.com/apk/res/android"
  android:id="@android:id/list"
  android:layout_width="match_parent"
  android:layout_height="match_parent"
  android:drawSelectorOnTop="false"
  android:choiceMode="multipleChoice"
/>
```

(from Selection/Checklist/app/src/main/res/layout/main.xml)

It is a full-screen `ListView`, with the `android:choiceMode="multipleChoice"` attribute to indicate that we want multiple choice support.

Our activity just uses a standard `ArrayAdapter` on our list of Latin words, but uses `android.R.layout.simple_list_item_multiple_choice` as the row layout:

```
package com.commonsware.android.checklist;

import android.app.ListActivity;
import android.os.Bundle;
import android.widget.ArrayAdapter;

public class ChecklistDemo extends ListActivity {
  private static final String[] items={"lorem", "ipsum", "dolor",
          "sit", "amet",
          "consectetuer", "adipiscing", "elit", "morbi", "vel",
          "ligula", "vitae", "arcu", "aliquet", "mollis",
          "etiam", "vel", "erat", "placerat", "ante",
          "porttitor", "sodales", "pellentesque", "augue", "purus"};

  @Override
  public void onCreate(Bundle state) {
    super.onCreate(state);
    setContentView(R.layout.main);
    setListAdapter(new ArrayAdapter<String>(this,
                        android.R.layout.simple_list_item_multiple_choice,
                        items));
  }
}
```

(from Selection/Checklist/app/src/main/java/com/commonsware/android/checklist/ChecklistDemo.java)

What the user sees is the list of words with checkboxes down the right edge:

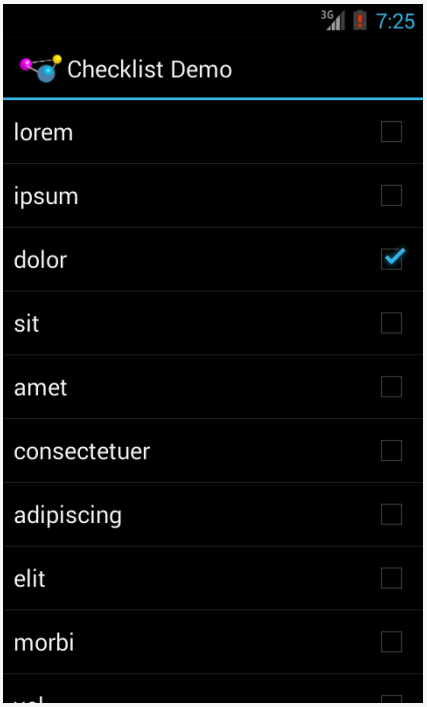

Figure 160: Multiple-Choice Mode

If we wanted, we could call methods like `getCheckedItemPositions()` on our `ListView` to find out which items the user checked, or `setItemChecked()` if we wanted to check (or un-check) a specific entry ourselves.

Clicks versus Selections, Revisited

If the user clicks a row in a `ListView`, a click event is registered, triggering things like `onListItemClick()` in an `OnItemClickListener`. If the user uses a pointing device to change a selection (e.g., pressing up and down arrows to move a highlight bar in the `ListView`), that triggers `onItemSelected()` in an `OnItemSelectedListener`.

Many times, particularly if the `ListView` is the entire UI at present, you only care about clicks. Sometimes, particularly if the `ListView` is adjacent to something else (e.g., on a TV, where you have more screen space *and* do not have a touchscreen), you will care more about selection events. Either way, you can get the events you need.

Spin Control

In Android, the `Spinner` is the equivalent of the drop-down selector you might find in other toolkits. Clicking the `Spinner` drops down a list for the user to choose an item from. You basically get the ability to choose an item from a list without taking up all the screen space of a `ListView`, at the cost of an extra click to make a change.

As with `ListView`, you provide the adapter for data and child views via `setAdapter()` and hook in a listener object for selections via `setOnItemSelectedListener()`.

To tailor the view used when displaying the drop-down perspective, you need to configure the adapter, not the `Spinner` widget. Use the `setDropDownViewResource()` method to supply the resource ID of the view to use.

For example, culled from the `Selection/Spinner` sample project, here is an XML layout for a simple view with a `Spinner`:

```
<?xml version="1.0" encoding="utf-8"?>
<LinearLayout
  xmlns:android="http://schemas.android.com/apk/res/android"
  android:orientation="vertical"
  android:layout_width="match_parent"
  android:layout_height="match_parent"
  >
  <TextView
    android:id="@+id/selection"
    android:layout_width="match_parent"
    android:layout_height="wrap_content"
    />
  <Spinner android:id="@+id/spinner"
    android:layout_width="match_parent"
    android:layout_height="wrap_content"
  />
</LinearLayout>
```

(from Selection/Spinner/app/src/main/res/layout/main.xml)

This is the same view as shown in a previous section, just with a `Spinner` instead of a `ListView`.

To populate and use the `Spinner`, we need some Java code:

```
public class SpinnerDemo extends Activity
  implements AdapterView.OnItemSelectedListener {
  private TextView selection;
  private static final String[] items={"lorem", "ipsum", "dolor",
          "sit", "amet",
          "consectetuer", "adipiscing", "elit", "morbi", "vel",
          "ligula", "vitae", "arcu", "aliquet", "mollis",
          "etiam", "vel", "erat", "placerat", "ante",
          "porttitor", "sodales", "pellentesque", "augue", "purus"};

  @Override
  public void onCreate(Bundle state) {
    super.onCreate(state);
    setContentView(R.layout.main);
    selection=(TextView)findViewById(R.id.selection);

    Spinner spin=(Spinner)findViewById(R.id.spinner);
    spin.setOnItemSelectedListener(this);

    ArrayAdapter<String> aa=new ArrayAdapter<String>(this,
                              android.R.layout.simple_spinner_item,
                              items);

    aa.setDropDownViewResource(
      android.R.layout.simple_spinner_dropdown_item);
    spin.setAdapter(aa);
  }

  @Override
  public void onItemSelected(AdapterView<?> parent,
                             View v, int position, long id) {
    selection.setText(items[position]);
  }

  @Override
  public void onNothingSelected(AdapterView<?> parent) {
    selection.setText("");
  }
}
```

(from Selection/Spinner/app/src/main/java/com/commonsware/android/selection/SpinnerDemo.java)

Here, we attach the activity itself as the selection listener (`spin.setOnItemSelectedListener(this)`), as `Spinner` widgets only support selection events, not click events. This works because the activity implements the `OnItemSelectedListener` interface. We configure the adapter not only with the list of fake words, but also with a specific resource to use for the drop-down view (via

`aa.setDropDownViewResource()`). Also note the use of `android.R.layout.simple_spinner_item` as the built-in `View` for showing items in the spinner itself. Finally, we implement the callbacks required by `OnItemSelectedListener` to adjust the selection label based on user input.

What we get is:

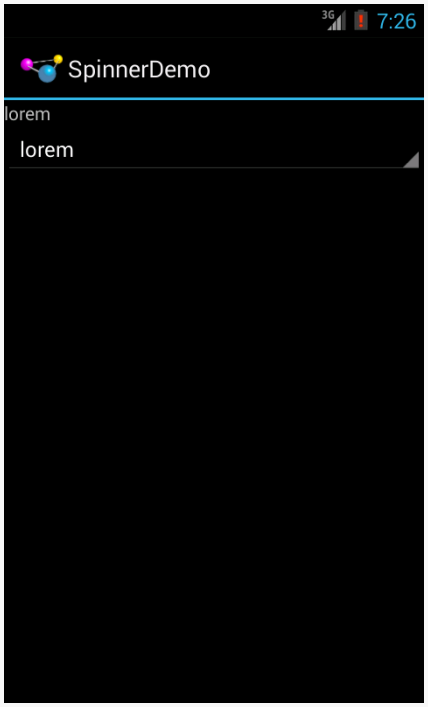

Figure 161: SpinnerDemo, as Initially Launched

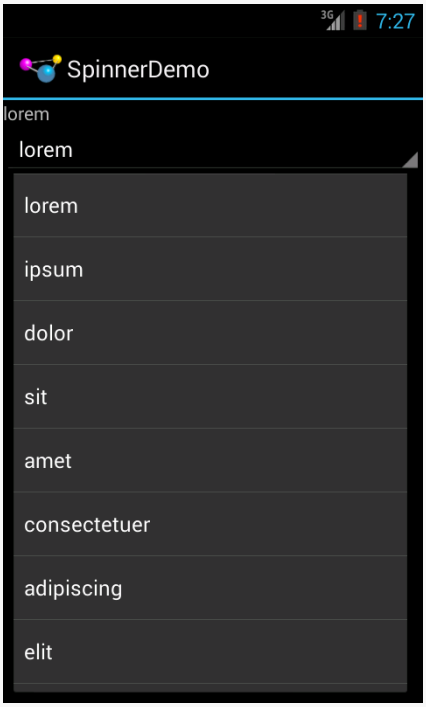

Figure 162: SpinnerDemo, with Spinner Drop-Down List Displayed

Grid Your Lions (Or Something Like That…)

As the name suggests, `GridView` gives you a two-dimensional grid of items to choose from. You have moderate control over the number and size of the columns; the number of rows is dynamically determined based on the number of items the supplied adapter says are available for viewing.

There are a few properties which, when combined, determine the number of columns and their sizes:

1. `android:numColumns` spells out how many columns there are, or, if you supply a value of `auto_fit`, Android will compute the number of columns based on available space and the properties listed below.
2. `android:verticalSpacing` and `android:horizontalSpacing` indicate how much whitespace there should be between items in the grid.
3. `android:columnWidth` indicates how wide each column should be, in terms of some dimension value (e.g., `40dp` or `@dimen/grid_column_width`).
4. `android:stretchMode` indicates, for grids with `auto_fit` for `android:numColumns`, what should happen for any available space not taken

up by columns or spacing — this should be `columnWidth` to have the columns take up available space or `spacingWidth` to have the whitespace between columns absorb extra space.

Otherwise, the `GridView` works much like any other selection widget — use `setAdapter()` to provide the data and child views, invoke `setOnItemClickListener()` to find out when somebody clicks on a cell in the grid, etc.

For example, here is an XML layout from the `Selection/Grid` sample project, showing a `GridView` configuration:

```
<?xml version="1.0" encoding="utf-8"?>
<LinearLayout
  xmlns:android="http://schemas.android.com/apk/res/android"
  android:orientation="vertical"
  android:layout_width="match_parent"
  android:layout_height="match_parent"
  >
  <TextView
    android:id="@+id/selection"
    android:layout_width="match_parent"
    android:layout_height="wrap_content"
    />
  <GridView
    android:id="@+id/grid"
    android:layout_width="match_parent"
    android:layout_height="match_parent"
    android:verticalSpacing="40dip"
    android:horizontalSpacing="5dip"
    android:numColumns="auto_fit"
    android:columnWidth="100dip"
    android:stretchMode="columnWidth"
    android:gravity="center"
    />
</LinearLayout>
```

(from Selection/Grid/app/src/main/res/layout/main.xml)

For this grid, we take up the entire screen except for what our selection label requires. The number of columns is computed by Android (`android:numColumns = "auto_fit"`) based on our horizontal spacing (`android:horizontalSpacing = "5dip"`) and columns width (`android:columnWidth = "100dip"`), with the columns absorbing any "slop" width left over (`android:stretchMode = "columnWidth"`).

The Java code to configure the `GridView` is:

```
package com.commonsware.android.grid;

import android.app.Activity;
import android.os.Bundle;
import android.view.View;
import android.widget.AdapterView;
import android.widget.ArrayAdapter;
import android.widget.GridView;
import android.widget.TextView;

public class GridDemo extends Activity
  implements AdapterView.OnItemClickListener {
  private TextView selection;
  private static final String[] items={"lorem", "ipsum", "dolor",
          "sit", "amet",
          "consectetuer", "adipiscing", "elit", "morbi", "vel",
          "ligula", "vitae", "arcu", "aliquet", "mollis",
          "etiam", "vel", "erat", "placerat", "ante",
          "porttitor", "sodales", "pellentesque", "augue", "purus"};

  @Override
  public void onCreate(Bundle state) {
    super.onCreate(state);
    setContentView(R.layout.main);
    selection=(TextView)findViewById(R.id.selection);

    GridView g=(GridView) findViewById(R.id.grid);
    g.setAdapter(new ArrayAdapter<String>(this,
                        R.layout.cell,
                        items));
    g.setOnItemClickListener(this);
  }

  @Override
  public void onItemClick(AdapterView<?> parent, View v,
                              int position, long id) {
    selection.setText(items[position]);
  }
}
```

(from Selection/Grid/app/src/main/java/com/commonsware/android/grid/GridDemo.java)

The grid cells are defined by a separate `res/layout/cell.xml` file, referenced in our `ArrayAdapter` as `R.layout.cell`:

```
<?xml version="1.0" encoding="utf-8"?>
<TextView
  xmlns:android="http://schemas.android.com/apk/res/android"
  android:layout_width="wrap_content"
  android:layout_height="wrap_content"
  android:textSize="14dip"
/>
```

(from Selection/Grid/app/src/main/res/layout/cell.xml)

With the vertical spacing from the XML layout (`android:verticalSpacing = "40dip"`), the grid overflows the boundaries of the emulator's screen:

Figure 163: GridDemo, as Initially Launched

Figure 164: GridDemo, Scrolled to the Bottom of the Grid

`GridView`, like `ListView`, supports both click events and selection events. In this sample, we register an `OnItemClickListener` to listen for click events.

Fields: Now With 35% Less Typing!

The `AutoCompleteTextView` is sort of a hybrid between the `EditText` (field) and the `Spinner`. With auto-completion, as the user types, the text is treated as a prefix filter, comparing the entered text as a prefix against a list of candidates. Matches are shown in a selection list that folds down from the field. The user can either type out an entry (e.g., something not in the list) or choose an entry from the list to be the value of the field.

`AutoCompleteTextView` subclasses `EditText`, so you can configure all the standard look-and-feel aspects, such as font face and color.

In addition, `AutoCompleteTextView` has an `android:completionThreshold` property, to indicate the minimum number of characters a user must enter before the list filtering begins.

You can give `AutoCompleteTextView` an adapter containing the list of candidate values via `setAdapter()`. However, since the user could type something not in the list, `AutoCompleteTextView` does not support selection listeners. Instead, you can register a `TextWatcher`, like you can with any `EditText`, to be notified when the text changes. These events will occur either because of manual typing or from a selection from the drop-down list.

Below we have a familiar-looking XML layout, this time containing an `AutoCompleteTextView` (pulled from the `Selection/AutoComplete` sample application):

```
<?xml version="1.0" encoding="utf-8"?>
<LinearLayout
  xmlns:android="http://schemas.android.com/apk/res/android"
  android:orientation="vertical"
  android:layout_width="match_parent"
  android:layout_height="match_parent"
  >
  <TextView
    android:id="@+id/selection"
    android:layout_width="match_parent"
    android:layout_height="wrap_content"
    />
  <AutoCompleteTextView android:id="@+id/edit"
      android:layout_width="match_parent"
      android:layout_height="wrap_content"
      android:completionThreshold="3"/>
</LinearLayout>
```

(from Selection/AutoComplete/app/src/main/res/layout/main.xml)

The corresponding Java code is:

```
package com.commonsware.android.auto;

import android.app.Activity;
import android.os.Bundle;
import android.text.Editable;
import android.text.TextWatcher;
import android.widget.ArrayAdapter;
import android.widget.AutoCompleteTextView;
import android.widget.TextView;

public class AutoCompleteDemo extends Activity
  implements TextWatcher {
  private TextView selection;
```

```
  private AutoCompleteTextView edit;
  private static final String[] items={"lorem", "ipsum", "dolor",
          "sit", "amet",
          "consectetuer", "adipiscing", "elit", "morbi", "vel",
          "ligula", "vitae", "arcu", "aliquet", "mollis",
          "etiam", "vel", "erat", "placerat", "ante",
          "porttitor", "sodales", "pellentesque", "augue", "purus"};

  @Override
  public void onCreate(Bundle state) {
    super.onCreate(state);
    setContentView(R.layout.main);
    selection=(TextView)findViewById(R.id.selection);
    edit=(AutoCompleteTextView)findViewById(R.id.edit);
    edit.addTextChangedListener(this);

    edit.setAdapter(new ArrayAdapter<String>(this,
                          android.R.layout.simple_dropdown_item_1line,
                          items));
  }

  @Override
  public void onTextChanged(CharSequence s, int start, int before,
                            int count) {
    selection.setText(edit.getText());
  }

  @Override
  public void beforeTextChanged(CharSequence s, int start,
                                int count, int after) {
    // needed for interface, but not used
  }

  @Override
  public void afterTextChanged(Editable s) {
    // needed for interface, but not used
  }
}
```

(from Selection/AutoComplete/app/src/main/java/com/commonsware/android/auto/AutoCompleteDemo.java)

This time, our activity implements `TextWatcher`, which means our callbacks are `onTextChanged()`, `beforeTextChanged()`, and `afterTextChanged()`. In this case, we are only interested in the first, and we update the selection label to match the `AutoCompleteTextView`'s current contents.

Here we have the results:

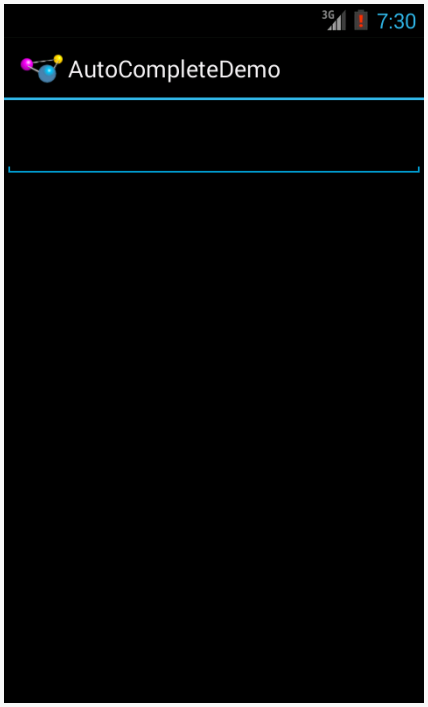

Figure 165: AutoCompleteDemo, as Initially Launched

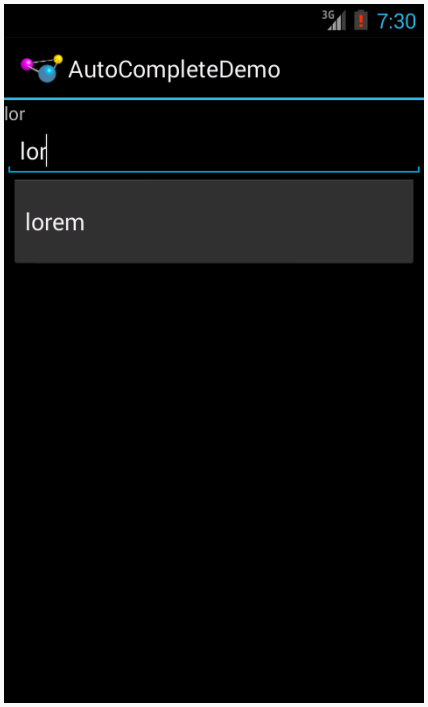

Figure 166: AutoCompleteDemo, After Entering a Few Matching Letters

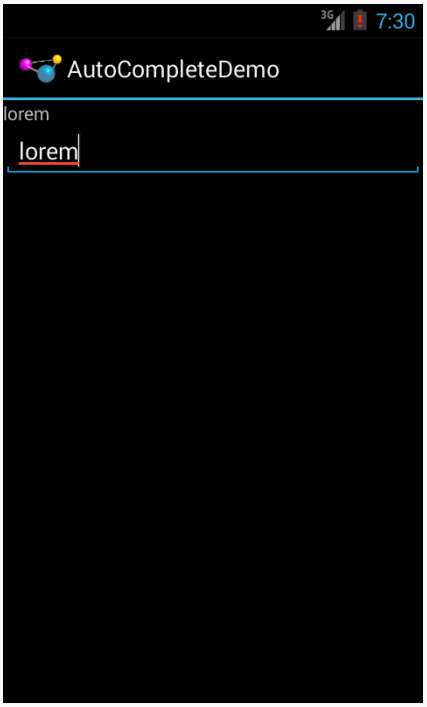

Figure 167: AutoCompleteDemo, After Auto-Complete Value Was Selected

Note that the red underline in the preceding screenshot is due to spelling correction. Like `EditText`, `AutoCompleteTextView` supports hinting at spelling errors. The emulator's language is set to English, as there is no option in it for Latin.

Customizing the Adapter

The humble `ListView` is one of the most important widgets in all of Android, simply because it is used so frequently. Whether choosing a contact to call or an email message to forward or an ebook to read, `ListView` widgets are employed in a wide range of activities.

Of course, it would be nice if they were more than just plain text.

The good news is that they can be as fancy as you want, within the limitations of a mobile device's screen, of course. However, making them more elaborate takes some work.

Note that while this section will be using `ListView` as the `AdapterView`, the same techniques hold for *any* `AdapterView`.

The Single Layout Pattern

The simplest way of creating custom `ListView` rows (or `GridView` cells or whatever) is when they all have the same basic structure and can be created from the same layout XML resource. This does not mean they have to be strictly identical, but that you can make whatever changes you need just by configuring the widgets (e.g., make some things `VISIBLE` or `GONE`).

This is not especially difficult, though it does take a few more steps than what we have seen previously.

Step #0: Get Things Set Up Simply

First, create your activity (e.g., `ListActivity`), get your data (e.g., array of Java strings), and set up your `AdapterView` with a simple adapter following the steps outlined in the preceding sections.

Here, we will examine the `Selection/Dynamic` sample project. We will use a simple `ListActivity` (taking the default layout of a full-screen `ListView`) and use the same list of 25 Latin words used in earlier samples. However, this time, we want to have a more elaborate row, taking into account the length of the Latin word.

Step #1: Design Your Row

Next, create a layout XML resource that will represent one row in your `ListView` (or cell in your `GridView` or whatever).

For example, our `res/layout/row.xml` resource will use a pair of nested `LinearLayout` containers to organize two `TextView` widgets and an `ImageView`:

```
<?xml version="1.0" encoding="utf-8"?>
<LinearLayout xmlns:android="http://schemas.android.com/apk/res/android"
  android:layout_width="match_parent"
  android:layout_height="wrap_content"
  android:orientation="horizontal">

  <ImageView
    android:id="@+id/icon"
    android:layout_width="wrap_content"
    android:layout_height="wrap_content"
    android:layout_gravity="center_vertical"
    android:padding="2dip"
```

```
    android:src="@drawable/ok"
    android:contentDescription="@string/icon"/>

  <LinearLayout
    android:layout_width="match_parent"
    android:layout_height="wrap_content"
    android:orientation="vertical">

    <TextView
      android:id="@+id/label"
      android:layout_width="wrap_content"
      android:layout_height="wrap_content"
      android:textSize="25sp"
      android:textStyle="bold"/>

    <TextView
      android:id="@+id/size"
      android:layout_width="wrap_content"
      android:layout_height="wrap_content"
      android:textSize="15sp"/>
  </LinearLayout>

</LinearLayout>
```

(from Selection/Dynamic/app/src/main/res/layout/row.xml)

The `ImageView` will use one of two drawable resources, one for short words, and another for long words.

Step #2: Extend ArrayAdapter

If you just used `R.layout.row` with a regular `ArrayAdapter`, it would work, insofar as it would not crash. However, `ArrayAdapter` only knows how to update a single `TextView` in a row, so it would ignore our other `TextView`, let alone the `ImageView`.

So, we need to create our own `ListAdapter`, by creating our own subclass of `ArrayAdapter`.

Since an `Adapter` is tightly coupled to the `AdapterView` that uses it, it is typically simplest to make the custom `ArrayAdapter` subclass be an inner class of whoever manages the `AdapterView`. Hence, in our sample, we will create an `IconicAdapter` inner class of our `ListActivity`.

Step #3: Override the Constructor and `getView()`

The `IconicAdapter` constructor can chain to the superclass and supply the necessary data, such as our Java array of Latin words. The real fun comes when we override `getView()`:

```
package com.commonsware.android.fancylists.three;

import android.app.ListActivity;
import android.os.Bundle;
import android.view.View;
import android.view.ViewGroup;
import android.widget.ArrayAdapter;
import android.widget.ImageView;
import android.widget.TextView;

public class DynamicDemo extends ListActivity {
  private static final String[] items={"lorem", "ipsum", "dolor",
          "sit", "amet",
          "consectetuer", "adipiscing", "elit", "morbi", "vel",
          "ligula", "vitae", "arcu", "aliquet", "mollis",
          "etiam", "vel", "erat", "placerat", "ante",
          "porttitor", "sodales", "pellentesque", "augue", "purus"};

  @Override
  public void onCreate(Bundle state) {
    super.onCreate(state);
    setListAdapter(new IconicAdapter());
  }

  class IconicAdapter extends ArrayAdapter<String> {
    IconicAdapter() {
      super(DynamicDemo.this, R.layout.row, R.id.label, items);
    }

    @Override
    public View getView(int position, View convertView,
                        ViewGroup parent) {
      View row=super.getView(position, convertView, parent);
      ImageView icon=(ImageView)row.findViewById(R.id.icon);

      if (items[position].length()>4) {
        icon.setImageResource(R.drawable.delete);
      }
      else {
        icon.setImageResource(R.drawable.ok);
      }

      TextView size=(TextView)row.findViewById(R.id.size);

      size.setText(String.format(getString(R.string.size_template), items[position].length()));

      return(row);
    }
  }
}
```

(from Selection/Dynamic/app/src/main/java/com/commonsware/android/fancylists/three/DynamicDemo.java)

Our `getView()` implementation does three things:

- It chains to the superclass' implementation of `getView()`, which returns to us an instance of our row `View`, as prepared by `ArrayAdapter`. In particular, our word has already been put into one `TextView`, since `ArrayAdapter` does that normally.
- It finds our `ImageView` and applies a business rule to set which icon should be used, referencing one of two drawable resources (`R.drawable.ok` and `R.drawable.delete`).
- It finds our other `TextView` and populates it as well, by pulling in the value of a string resource and using `String.format()` to pour in our word length.

Note that we call `findViewById()` not on the activity, but rather on the row returned by the superclass' implementation of `getView()`. **Always call `findViewById()` on something that is guaranteed to give you a unique result.** In the case of an `AdapterView`, there will be many rows, cells, etc. — calling `findViewById()` on the activity might return widgets with the right name but from other rows or cells.

This gives us:

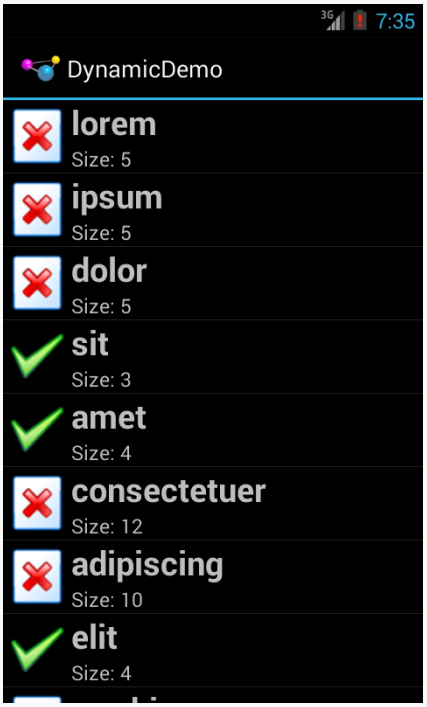

Figure 168: The Dynamic Sample Application

The approach of overriding `getView()` works for `ArrayAdapter`, but some other types of adapters would have alternatives. We will see that mostly with `CursorAdapter`, profiled in upcoming chapters.

Optimizing with the ViewHolder Pattern

A somewhat expensive operation we do a lot with more elaborate list rows is call `findViewById()`. This dives into our row and pulls out widgets by their assigned identifiers, so we can customize the widget contents (e.g., change the text of a `TextView`, change the icon in an `ImageView`). Since `findViewById()` can find widgets anywhere in the tree of children of the row's root `View`, this could take a fair number of instructions to execute, particularly if we keep having to re-find widgets we had found once before.

In some GUI toolkits, this problem is avoided by having the composite `View` objects, like our rows, be declared totally in program code (in this case, Java). Then, accessing individual widgets is merely the matter of calling a getter or accessing a field. And you can certainly do that with Android, but the code gets rather verbose. What would be nice is a way where we can still use the layout XML yet cache our row's key child widgets so we only have to find them once.

That's where the holder pattern comes into play, in a class we will call `ViewHolder`.

All `View` objects have `getTag()` and `setTag()` methods. These allow you to associate an arbitrary object with the widget. What the holder pattern does is use that "tag" to hold an object that, in turn, holds each of the child widgets of interest. By attaching that holder to the row `View`, every time we use the row, we already have access to the child widgets we care about, without having to call `findViewById()` again.

So, let's take a look at one of these holder classes (taken from the `Selection/ViewHolder` sample project, a revised version of the `Selection/Dynamic` sample from before):

```
package com.commonsware.android.fancylists.five;

import android.view.View;
import android.widget.ImageView;
import android.widget.TextView;

class ViewHolder {
  ImageView icon=null;
  TextView size=null;

  ViewHolder(View row) {
    this.icon=(ImageView)row.findViewById(R.id.icon);
    this.size=(TextView)row.findViewById(R.id.size);
  }
}
```

(from Selection/ViewHolder/app/src/main/java/com/commonsware/android/fancylists/five/ViewHolder.java)

`ViewHolder` holds onto the child widgets, initialized via `findViewById()` in its constructor. The widgets are simply package-protected data members, accessible from other classes in this project... such as a `ViewHolderDemo` activity. In this case, we are only holding onto two widgets — the icon and the second label – since we will let `ArrayAdapter` handle our first label for us. In our case, we are holding onto the `TextView` and `ImageView` widgets that we want to populate in `getView()`.

Using `ViewHolder` is a matter of creating an instance whenever we inflate a row and attaching said instance to the row `View` via `setTag()`, as shown in this rewrite of `getView()`, found in `ViewHolderDemo`:

```
    @Override
    public View getView(int position, View convertView,
                        ViewGroup parent) {
      View row=super.getView(position, convertView, parent);
```

```
    ViewHolder holder=(ViewHolder)row.getTag();

    if (holder==null) {
      holder=new ViewHolder(row);
      row.setTag(holder);
    }

    if (getModel(position).length()>4) {
      holder.icon.setImageResource(R.drawable.delete);
    }
    else {
      holder.icon.setImageResource(R.drawable.ok);
    }

    holder.size.setText(String.format(getString(R.string.size_template), items[position].length()));

    return(row);
  }
```

(from Selection/ViewHolder/app/src/main/java/com/commonsware/android/fancylists/five/ViewHolderDemo.java)

If the call to `getTag()` on the row returns `null`, we know we need to create a new `ViewHolder`, which we then attach to the row via `setTag()` for later reuse. Then, accessing the child widgets is merely a matter of accessing the data members on the holder.

This takes advantage of the fact that rows in a `ListView` get *recycled* – a 25,000-row list does not create 25,000 rows. The recycling itself is handled for us by `ArrayAdapter`, so we simply have to create our `ViewHolder` when needed and reuse the existing `ViewHolder` when a row gets recycled. The first time the `ListView` is displayed, all new rows need to be created, and we wind up creating a `ViewHolder` for each. As the user scrolls, rows get recycled, and we can reuse their corresponding `ViewHolder` widget caches. We will cover this recycling process in greater detail in a later chapter.

Note that the `getModel()` method shown here retrieves our model `String` for a given `position`, by using `getListAdapter()` (to retrieve our `IconicAdapter` from the activity's `ListView`) and `getItem()` (to retrieve the data, held by the adapter, represented by the position):

```
  private String getModel(int position) {
    return(((IconicAdapter)getListAdapter()).getItem(position));
  }
```

(from Selection/ViewHolder/app/src/main/java/com/commonsware/android/fancylists/five/ViewHolderDemo.java)

Dealing with Multiple Row Layouts

The story gets significantly more complicated if our mix of rows is more complicated. For example, here is the Sound screen in the Settings application:

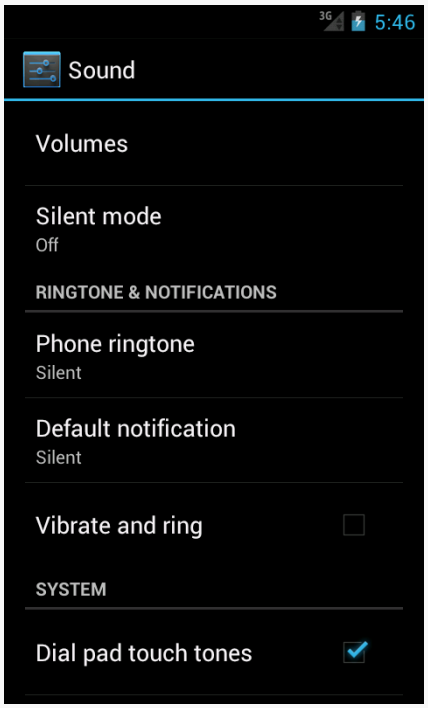

Figure 169: Sound Settings Screen

It may not look like it, but that is a `ListView`. However, not all the rows look the same:

- Some have one line of text (e.g., "Volumes")
- Some have two lines of text (e.g., "Silent mode" plus "Off")
- Some have one line of text and a `CheckBox` (e.g., "Vibrate and ring")
- Some are headings with totally different text formatting (e.g., "RINGTONE & NOTIFICATIONS")

This is handled by having more than one row layout XML resource used by the adapter. The complexity comes not only in managing those different resources and determining which to use when, but in just having more than one resource – after all, we only teach `ArrayAdapter` how to use one. We will examine how to handle this scenario in a later chapter.

Visit the Trails!

To learn more about `ListView`, you can turn to Advanced ListViews, which covers other tricks you can do with a `ListView`.

`RecyclerView` is a more powerful (and more complex) replacement for `ListView` and `GridView`. You can read more about what it does and how you can use it.

The WebView Widget

HTML has come a *long* way from Sir Tim Berners-Lee's original vision of using it to publish physics papers.

Not surprisingly, displaying HTML, CSS, and JavaScript in mobile applications is fairly popular, not only for creating full-fledged Web browsers, but for rendering HTML content from RSS/Atom feeds, from HTML-formatted email messages, ebooks (like the one you are reading), and so forth.

There are a couple of ways to display HTML in Android, with the most powerful being the `WebView` widget, the focus of this chapter.

Role of WebView

If your HTML is fairly limited in scope, such as what you might find in the body of a status update on Twitter, you can use the static `fromHtml()` method on the `Html` utility class to parse an HTML-formatted string into something that you can put into a `TextView`. `TextView` can render simple formatting like styles (bold, italic, etc.), font faces (serif, sans serif, etc.), colors, links, and so forth.

However, sometimes your needs for HTML transcend what `TextView` can handle. You will not be browsing Facebook using `TextView`, for example.

In those cases, `WebView` will be the more appropriate widget, as it can handle a *much* wider range of HTML tags. `WebView` can also handle CSS and JavaScript, which `Html.fromHtml()` would simply ignore. `WebView` can also assist you with common "browsing" metaphors, such as history list of visited URLs to support backwards and forwards navigation.

On the other hand, `WebView` is a much more expensive widget to use, in terms of memory consumption, than is `TextView`.

Daddy, Where Do WebViews Come From?

Originally, the story was simple: `WebView` was powered by a fairly complete copy of WebKit, the Web rendering engine behind Safari and, originally, Chrome.

In Android 4.4, Google switched rendering engines. Depending on who you asked, `WebView` was powered by Chromium or Blink. Chromium is an open source browser that forms the foundation for Google's Chrome, and Blink is a fork of WebKit created by Opera and Google that, in turn, powers Chromium.

Starting in Android 5.0, the implementation of `WebView` was no longer a part of Android. Rather, it became a separate "System WebView" app, distributed through the Play Store. The idea was that this app could be updated independently of the device firmware, so that `WebView` bugs could be fixed more rapidly and distributed to more devices. This also means that Google can distribute new and exciting bugs more quickly (and independently of Android OS version), as will be discussed later in the chapter.

In Android 7.0, the implementation of `WebView` will be from one of two places:

- the proprietary Chrome browser app, or
- the System WebView app, for devices where Chrome is disabled

The documented dependency of `WebView` on apps distributed through the Play Store makes things very murky for non-Play ecosystem devices, such as most devices in China. Most likely, individual manufacturers do their own thing with respect to updating `WebView`.

As a result, from the standpoint of security and compatibility, `WebView` is a "hot mess".

Adding the Widget

For simple stuff, `WebView` is not significantly different than any other widget in Android — pop it into a layout, tell it what URL to navigate to via Java code, and you are done.

As you can see in the WebKit/Browser1 sample application, here is a simple layout with a WebView:

```
<?xml version="1.0" encoding="utf-8"?>
<WebView xmlns:android="http://schemas.android.com/apk/res/android"
  android:id="@+id/webkit"
  android:layout_width="match_parent"
  android:layout_height="match_parent"
/>
```

(from WebKit/Browser1/app/src/main/res/layout/main.xml)

As with any other widget, you need to tell it how it should fill up the space in the layout (in this case, it fills all remaining space).

And, just as with other widgets, you can add it using your IDE's graphical layout editor. An Android Studio user can drag a WebView out of the "Containers" section of the tool palette.

Note that WebView knows how to scroll its own contents, so you do not need to put it in a ScrollView or HorizontalScrollView.

Loading Content Via a URL

There are a number of ways to load HTML content into a WebView widget.

The simplest is to use the loadUrl() method, which takes a URL and retrieves its contents over the Internet. For example, here is the activity source code for the WebKit/Browser1 sample application:

```
package com.commonsware.android.browser1;

import android.app.Activity;
import android.os.Bundle;
import android.webkit.WebView;

public class BrowserDemo1 extends Activity {
  WebView browser;

  @Override
  public void onCreate(Bundle state) {
    super.onCreate(state);
    setContentView(R.layout.main);
    browser=(WebView)findViewById(R.id.webkit);
```

```
    browser.loadUrl("https://commonsware.com");
  }
}
```

(from WebKit/Browser1/app/src/main/java/com/commonsware/android/browser1/BrowserDemo1.java)

However, we also have to make one change to `AndroidManifest.xml`, adding a line where we request permission to access the Internet:

```
  <uses-permission android:name="android.permission.INTERNET"/>
```

(from WebKit/Browser1/app/src/main/AndroidManifest.xml)

If we fail to add this permission, the browser will refuse to load pages. We will discuss more about this "permission" concept in a later chapter.

The resulting activity looks like a Web browser, just with hidden scrollbars:

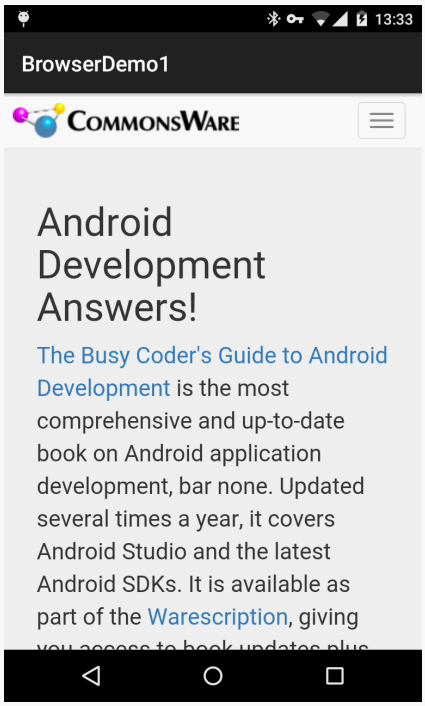

Figure 170: The Browser1 Sample Application (image from June 2015)

As with a regular Android Web browser, you can pan around the page by dragging it, while the directional pad moves you around all the focusable elements on the page.

What is missing is all the extra stuff that make up a Web browser, such as a navigational toolbar. `WebView` does not provide any of that — if you want those sorts of UI features, you will need to implement those yourself (e.g., use an `EditText` or `AutoCompleteTextView` for a browser address bar).

Links and Redirects

The sample shown above loads the CommonsWare home page. The links in that page are clickable. Exactly what happens when you click on the link, though, depends upon circumstances.

Traditionally, the default behavior for when the user clicks on a link in a `WebView` is for the linked-to Web page to be launched in a Web browser. However, the "Android System WebView" released in early June 2015 changed that default behavior, so now the linked-to Web page opens up in the `WebView` itself. Since Android 4.4 and older devices do not have the "Android System WebView", this means that the default behavior of link clicks varies by device, which is not fun.

Also, if you try loading a page using `loadUrl()`, and the server issues a server-side redirect (e.g., HTTP 301 or 304 response), the default behavior is the same as a simple click of a link:

- On devices with "Android System WebView" 43.0.2357.121 or newer, the redirected-to page shows up in the `WebView`
- Everywhere else, the redirected-to page appears in a separate Web browser app

We will cover how to address this problem later in this chapter.

Supporting JavaScript

Now, you may be tempted to replace the URL in the above source code with something else, such as Google's home page or something else that relies upon JavaScript. You will find that such pages do not work especially well by default. That is because, by default, JavaScript is turned off in `WebView` widgets.

If you want to enable JavaScript, call `getSettings().setJavaScriptEnabled(true);` on the `WebView` instance. At this point, any JavaScript referenced by your Web page should work normally.

There are some fancy tricks you can perform with `WebView` and JavaScript, such as having JavaScript call Java code or vice versa. These techniques will be covered in a later chapter.

Alternatives for Loading Content

`loadUrl()` works with:

- `http://` and `https://` URLs
- `file://` URLs pointing to the local filesystem
- `file:///android_asset/` URLs pointing to one of your application's assets, as will be discussed later in this book
- `content://` URLs pointing to a `ContentProvider` that is publishing content available for streaming, as will be discussed much later in this book

Instead of `loadUrl()`, you can also use `loadData()`. Here, you supply the HTML for the `WebView` to display. You might use this to:

1. display a manual that was installed as a file with your application package
2. display snippets of HTML you retrieved as part of other processing, such as the description of an entry in an Atom feed
3. generate a whole user interface using HTML, instead of using the Android widget set

There are two flavors of `loadData()`. The simpler one allows you to provide the content, the MIME type, and the encoding, all as strings. Typically, your MIME type will be `text/html` and your encoding will be `UTF-8` for ordinary HTML.

For example, if you replace the `loadUrl()` invocation in the previous example with the following:

```
browser.loadData("<html><body>Hello, world!</body></html>",
                 "text/html", "UTF-8");
```

You get:

Figure 171: The Browser2 sample application

This is also available as a fully-buildable sample, as `WebKit/Browser2`.

There is also a `loadDataWithBaseURL()` method. This takes, among other parameters, the "base URL" to use when resolving relative URLs in the HTML. Any relative URL (e.g., `<img src="images/foo.png">`) will be interpreted as being relative to the base URL supplied to `loadDataWithBaseURL()`. If you find that you have content that refuses to load properly with `loadData()`, try `loadDataWithBaseURL()` with a `null` base URL, as sometimes that works better, for unknown reasons.

Listening for Events

Particularly if you are going to use the `WebView` as a local user interface (vs. browsing the Web), you will want to be able to get control at key times, particularly when users click on links. You will want to make sure those links are handled properly, either by loading your own content back into the `WebView`, by submitting an `Intent` to Android to open the URL in a full browser, or by some other means. We will discuss using an `Intent` to launch a Web browser in a later chapter.

One hook into the `WebView` activity is via `setWebViewClient()`, which takes an instance of a `WebViewClient` implementation as a parameter. The supplied callback object will be notified of a wide range of events, ranging from when parts of a page have been retrieved (`onPageStarted()`, etc.) to when you, as the host application, need to handle certain user- or circumstance-initiated events, such as:

1. `onTooManyRedirects()`
2. `onReceivedHttpAuthRequest()`
3. etc.

A common hook will be `shouldOverrideUrlLoading()`, where your callback is passed a URL (plus the `WebView` itself) and you return `true` if you will handle the request or `false` if you want default handling (e.g., actually fetch the Web page referenced by the URL). In the case of a feed reader application, for example, you will probably not have a full browser with navigation built into your reader, so if the user clicks a URL, you probably want to use an `Intent` to ask Android to load that page in a full browser. But, if you have inserted a "fake" URL into the HTML, representing a link to some activity-provided content, you can update the `WebView` yourself.

For example, let's amend the first browser example to be an application that, upon a click, shows the current time.

From [WebKit/Browser3], here is the revised Java:

```
package com.commonsware.android.webkit;

import android.app.Activity;
import android.os.Bundle;
import android.text.format.DateUtils;
import android.webkit.WebView;
import android.webkit.WebViewClient;
import java.util.Date;

public class BrowserDemo3 extends Activity {
  WebView browser;

  @Override
  public void onCreate(Bundle icicle) {
    super.onCreate(icicle);
    setContentView(R.layout.main);
    browser=(WebView)findViewById(R.id.webkit);
    browser.setWebViewClient(new Callback());
```

```
    loadTime();
  }

  void loadTime() {
    String page=
        "<html><body><a href='http://webview.used.to.be.less.annoying/clock'>"
            + DateUtils.formatDateTime(this, new Date().getTime(),
                                       DateUtils.FORMAT_SHOW_DATE
                                           | DateUtils.FORMAT_SHOW_TIME)
            + "</a></body></html>";

    browser.loadData(page, "text/html", "UTF-8");
  }

  private class Callback extends WebViewClient {
    @Override
    public boolean shouldOverrideUrlLoading(WebView view, String url) {
      loadTime();

      return(true);
    }
  }
}
```

Here, we load a simple Web page into the browser (`loadTime()`) that consists of the current time, made into a hyperlink to a fake URL. We also attach an instance of a `WebViewClient` subclass, providing our implementation of `shouldOverrideUrlLoading()`. In this case, no matter what the URL, we want to just reload the `WebView` via `loadTime()`.

Running this activity gives us:

Figure 172: The Browser3 Sample Application

Clicking the link will cause us to rebuild the page with the new time.

Note that we are using a `DateUtils` utility class supplied by Android for formatting our date and time. The big advantage of using `DateUtils` is that this class is aware of the user's settings for how they prefer to see the date and time (e.g., 12- versus 24-hour mode).

There is also a `WebChromeClient` that you can register with a `WebView` via a call to `setWebChromeClient()`. This object will be called when various things occur in the `WebView` that might pertain to a browser's "chrome" (i.e., the things outside the HTML rendering area). For example, `onJSAlert()` will be called on your `WebChromeClient` when JavaScript code calls `alert()`.

Addressing the Link/Redirect Behavior

Given that Google, through "Android System WebView" 43.0.2357.121, has changed the default behavior for when users click on links or redirects, it is in your best interests to *avoid the default*, since the default varies.

To do this, you can use `WebViewClient` and `shouldOverrideUrlLoading()`, as indicated above.

The WebKit/Browser4 is a clone of the original sample from this chapter, with one change: adding in a `WebViewClient` to force all link clicks to alter the `WebView` contents, regardless of what version of Android or the "Android System WebView" we are using:

```
package com.commonsware.android.browser4;

import android.app.Activity;
import android.os.Bundle;
import android.webkit.WebView;
import android.webkit.WebViewClient;

public class BrowserDemo4 extends Activity {
  WebView browser;

  @Override
  public void onCreate(Bundle state) {
    super.onCreate(state);
    setContentView(R.layout.main);
    browser=(WebView)findViewById(R.id.webkit);

    browser.setWebViewClient(new WebViewClient() {
      @Override
      public boolean shouldOverrideUrlLoading(WebView view, String url) {
        view.loadUrl(url);

        return(true);
      }
    });

    browser.loadUrl("http://commonsware.com");
  }
}
```

(from WebKit/Browser4/app/src/main/java/com/commonsware/android/browser4/BrowserDemo4.java)

Here, the `WebViewClient` is an instance of an anonymous inner class, and `shouldOverrideUrlLoading()` just turns around and calls `loadUrl()` on the `WebView` to handle the new URL. `shouldOverrideUrlLoading()` returns `true` to indicate that it is handling the event.

Visit the Trails!

You can learn more about powerful tricks with `WebView`, including integrating the Java and JavaScript environments, in a later chapter.

Defining and Using Styles

As noted in an earlier chapter, Android offers styles and themes, filling the same sort of role that CSS does in Web development. In that earlier chapter, we covered the basic roles of styles and themes, plus introduced the three classic theme families:

- `Theme`
- `Theme.Holo`
- `Theme.Material`

In this chapter, we will take a slightly "deeper dive" into styles and themes, exploring how you can create your own and apply them to your app's UI.

Styles: DIY DRY

The purpose of styles is to encapsulate a set of attributes that you intend to use repeatedly, conditionally, or otherwise wish to keep separate from your layouts proper. The primary use case is "don't repeat yourself" (DRY) — if you have a bunch of widgets that look the same, use a style to use a single definition for "look the same", rather than copying the look from widget to widget.

And that paragraph will make a bit more sense if we look at an example, specifically the `Styles/NowStyled` sample project. This is a trivial project, with a full-screen button that shows the date and time of when the activity was launched or when the button was pushed. This time, though, we want to change the way the text on the face of the button appears, and we will do so using a style.

The `res/layout/main.xml` file in this project has a `style` attribute on the `Button`:

```
<?xml version="1.0" encoding="utf-8"?>
<Button xmlns:android="http://schemas.android.com/apk/res/android"
  android:id="@+id/button"
  android:text=""
  android:layout_width="match_parent"
  android:layout_height="match_parent"
  style="@style/bigred"
/>
```

(from Styles/NowStyled/app/src/main/res/layout/main.xml)

Note that the `style` attribute is part of stock XML and therefore is not in the `android` namespace, so it does not get the `android:` prefix.

The value, `@style/bigred`, points to a style resource. Style resources are values resources and can be found in the `res/values/` directory in your project, or in other resource sets (e.g., `res/values-v11/` for values resources only to be used on API Level 11 or higher). The convention is for style resources to be held in a `styles.xml` file, such as the one from the `NowStyled` project:

```
<?xml version="1.0" encoding="utf-8"?>
<resources>
  <style name="bigred">
    <item name="android:textSize">30sp</item>
    <item name="android:textColor">#FFFF0000</item>
  </style>
</resources>
```

(from Styles/NowStyled/app/src/main/res/values/styles.xml)

The `<style>` element supplies the name of the style, which is what we use when referring to the style from a layout. The `<item>` children of the `<style>` element represent values of attributes to be applied to whatever the style is applied towards — in our example, our `Button` widget. So, our `Button` will have a comparatively large font (`android:textSize` set to `30sp`) and have the text appear in red (`android:textColor` set to `#FFFF0000`).

Just defining the style and applying it to the widget gives us the desired results:

Figure 173: The Styles/NowStyled sample application

Elements of Style

There are four elements to consider when applying a style:

- Where do you put the style attributes to say you want to apply a style?
- What attributes can you define via a style?
- How do you inherit from a previously-defined style (one of your own or one from Android)?
- What values can those attributes have in a style definition?

Where to Apply a Style

The `style` attribute can be applied to a widget, to only affect that widget.

The `style` attribute can be applied to a container, to affect that container. However, doing this does not automatically style its children. For example, suppose `res/layout/main.xml` looked instead like this:

```
<?xml version="1.0" encoding="utf-8"?>
<LinearLayout xmlns:android="http://schemas.android.com/apk/res/android"
    android:layout_width="match_parent"
    android:layout_height="match_parent"
    style="@style/bigred">
  <Button
    android:id="@+id/button"
    android:text=""
    android:layout_width="match_parent"
    android:layout_height="match_parent"
  />
</LinearLayout>
```

The resulting UI would not have the `Button` text in a big red font, despite the `style` attribute. The style only affects the container, not the contents of the container.

You can also apply a style to an activity or an application as a whole, though then it is referred to as a "theme", which will be covered a bit later in this chapter.

The Available Attributes

When styling a widget or container, you can apply any of that widget's or container's attributes in the style itself. So, if it shows up in the "XML Attributes" or "Inherited XML Attributes" portions of the Android JavaDocs, you can put it in a style.

Note that Android will ignore invalid styles. So, had we applied the `bigred` style to the `LinearLayout` as shown above, everything would run fine, just with no visible results. Despite the fact that `LinearLayout` has no `android:textSize` or `android:textColor` attribute, there is no compile-time failure nor a runtime exception.

Also, layout directives, such as `android:layout_width`, can be put in a style.

Inheriting a Style

You can also indicate that you want to inherit style attributes from another style, by specifying a `parent` attribute on the `<style>` element.

For example, take a look at this style resource:

```
<?xml version="1.0" encoding="utf-8"?>
<resources>
  <style name="activated" parent="android:Theme.Holo">
```

```
    <item name="android:background">?android:attr/activatedBackgroundIndicator</item>
  </style>
</resources>
```

(note: in some renditions of this book, you may see the `<item>` element split over two lines — this is caused by word-wrapping, as this element should be all on one line)

Here, we are indicating that we want to inherit the `Theme.Holo` style from within Android. Hence, in addition to all of our own attribute definitions, we are specifying that we want all of the attribute definitions from `Theme.Holo` as well.

In many cases, this will not be necessary. If you do not specify a parent, your attribute definitions will be blended into whatever default style is being applied to the widget or container.

That `?android:attr` looks a bit bizarre, but we will get into what that syntax means in the next section.

The Possible Values

Typically, the value that you will give those attributes in the style will be some constant, like `30sp` or `#FFFF0000`.

Sometimes, though, you want to perform a bit of indirection — you want to apply some other attribute value from the theme you are inheriting from. In that case, you will wind up using the somewhat cryptic `?android:attr/` syntax, along with a few related magic incantations.

For example, let's look again at this style resource:

```
<?xml version="1.0" encoding="utf-8"?>
<resources>
  <style name="activated" parent="android:Theme.Holo">
    <item name="android:background">?android:attr/activatedBackgroundIndicator</item>
  </style>
</resources>
```

Here, we are indicating that the value of `android:background` is not some constant value, or even a reference to a drawable resource (e.g., `@drawable/my_background`). Instead, we are referring to the value of some other attribute — `activatedBackgroundIndicator` — from our inherited theme. Whatever the theme

defines as being the `activatedBackgroundIndicator` is what our background should be.

This portion of the Android style system is very under-documented, to the point where Google itself recommends you look at the Android source code listing the various styles to see what is possible.

This is one place where inheriting a style becomes important. In the example shown in this section, we inherited from `Theme.Holo`, because we specifically wanted the `activatedBackgroundIndicator` value from `Theme.Holo`. That value might not exist in other styles, or it might not have the value we want.

Themes: Would a Style By Any Other Name…

Themes are styles, applied to an activity or application, via an `android:theme` attribute on the `<activity>` or `<application>` element. If the theme you are applying is your own, just reference it as `@style/...`, just as you would in a `style` attribute of a widget. If the theme you are applying, though, comes from Android, typically you will use a value with `@android:style/` as the prefix, such as `@android:style/Theme.Holo.Dialog` or `@android:style/Theme.Holo.Light`.

In a theme, your focus is not so much on styling widgets, but styling the activity itself. For example, here is the definition of `@android:style/Theme.Holo.NoActionBar.Fullscreen`:

```
<!-- Variant of the default (dark) theme that has no title bar and
          fills the entire screen -->
<style name="Theme.Holo.NoActionBar.Fullscreen">
  <item name="android:windowFullscreen">true</item>
  <item name="android:windowContentOverlay">@null</item>
</style>
```

It specifies that the activity should take over the entire screen, removing the status bar on phones (`android:windowFullscreen` set to `true`). It also specifies that the "content overlay" — a layout that wraps around your activity's content view — should be set to nothing (`android:windowContentOverlay` set to `@null`), having the effect of removing the title bar.

What Happens If You Have No Theme

Most of the sample apps that we have examined so far have not defined a theme, either at the `<application>` level or the `<activity>` level. What happens here then depends upon the device that your app runs upon:

- On an Android 1.x or 2.x device, you will get `Theme` as your theme
- On an Android 3.x or 4.x device, if your `minSdkVersion` or `targetSdkVersion` is 11 or higher, you will get `Theme.Holo` as your theme; otherwise, you will stick with `Theme` as your theme
- On an Android 5.0+ device, if your `targetSdkVersion` is 14 or higher, you will get `Theme.Material` as your theme; otherwise, your app behaves as in the 3.x/4.x scenario above

As a result, your app is far from "broken", despite the lack of an explicit theme. It does mean, though, that your app will have a different look on those different Android OS levels, a look that will tend to have your app blend in more with other apps on that same device.

However, once you want to start customizing your theme, you will now run into a problem: having different themes for different OS versions. An Android 2.x device knows nothing about `Theme.Material`, for example, so you cannot simply create a custom theme based on `Theme.Material` and expect it to work. As we will see in a later chapter, the solution winds up being *versioned resources*, where you have different theme definitions for different API levels.

Of course, if your `minSdkVersion` is high enough, resource versioning is less of an issue. For example, if your `minSdkVersion` is 21, all devices that your app runs upon should know about `Theme.Material`, just as if your `minSdkVersion` were 11 or higher, all devices that your app would run on would know about `Theme.Holo`.

Android Studio's Theme Editor

Android Studio has a dedicated theme editor, which allows you to (somewhat) preview your theme and (somewhat) modify it visually.

When you open a style or theme resource, you will get a banner across the top of the XML editor, offering to open the theme in the theme editor:

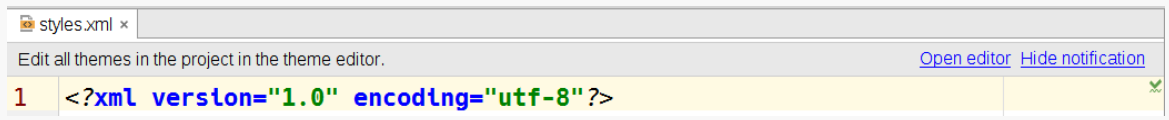

Figure 174: The Styles/NowStyled Style Resource, with Banner

Clicking the "Open editor" link in that banner will bring up the Theme Editor tab:

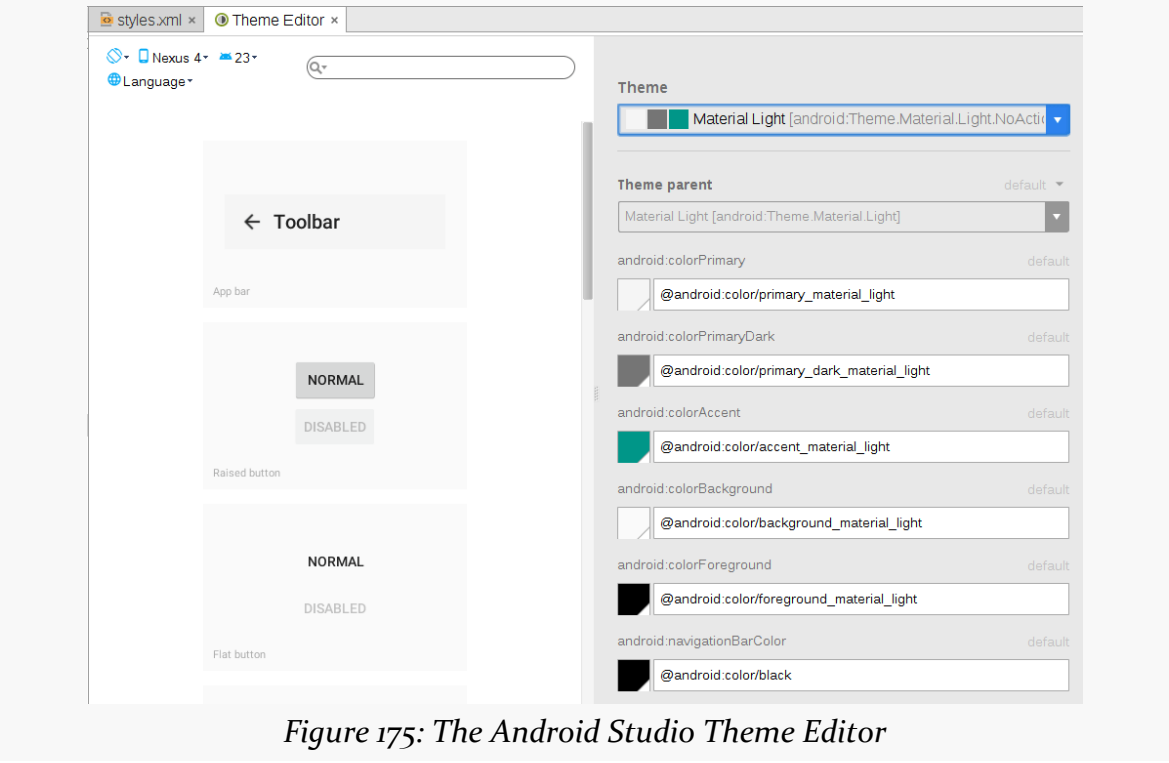

Figure 175: The Android Studio Theme Editor

If the style resource does not define a style being used as a theme – as is the case with the `NowStyled` sample app, you wind up with a pretty, albeit read-only, way of seeing how colors and settings in the theme will affect the action bar (labeled here as the "app bar"), buttons, and so forth.

If you open the Theme Editor on a style resource that is being used as a theme, you may get a preview of that custom theme:

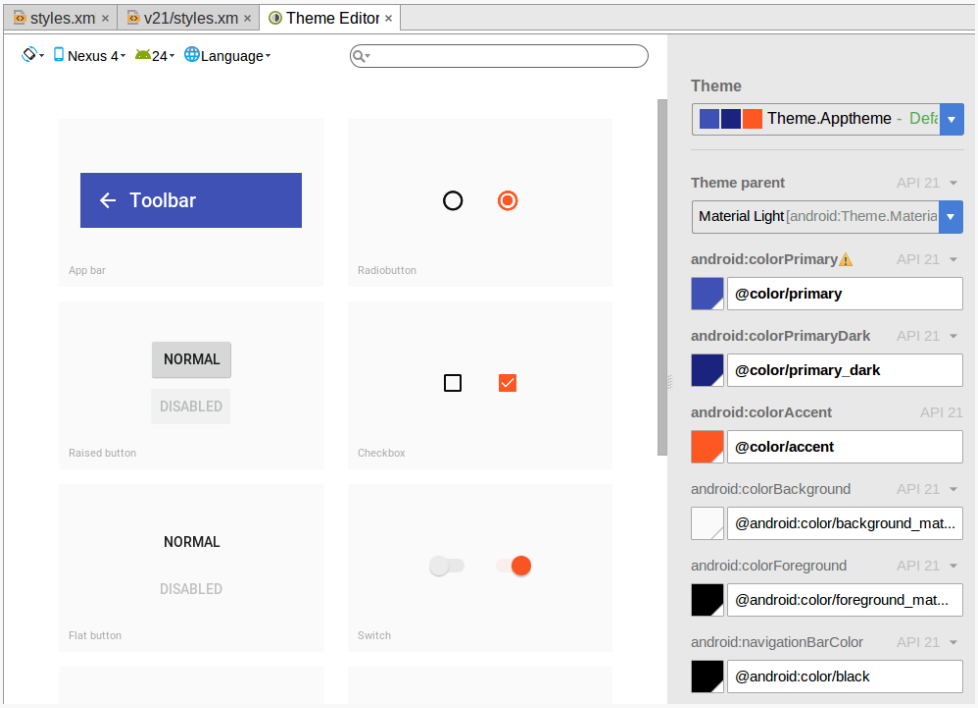

Figure 176: The Android Studio Theme Editor, For an Actual Theme

In places where you have overridden certain colors, such as the `android:colorPrimary` attribute for a `Theme.Material`-based theme, you can use a color picker to replace that color with a different value:

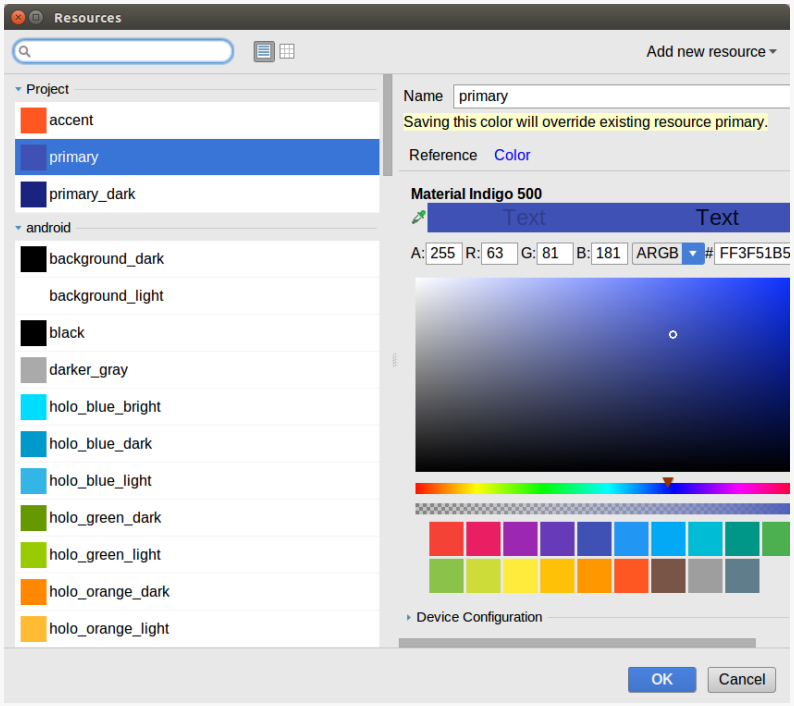

Figure 177: The Android Studio Theme Editor's Color Picker Dialog

As the dialog notes, if you change the color in the dialog, the editor will update the associated resources to match, and show you the revised value in the preview:

Dependencies

While you are writing some code for an app, the vast majority of the code that *is* the app comes from other developers. Some might be teammates on your development team, but far more comes from outsiders: Google and other Android developers.

Some of this you have seen already. You did not write `Activity`, `TextView`, and similar classes. Instead, they came from the Android SDK, written (primarily) by Google.

Beyond the Android SDK, though, there are thousands of libraries that developers have access to, including many from Google itself. We add these as dependencies in our projects, to use their code alongside ours.

What's a Dependency?

Roughly speaking, the code and assets that make up an app come from three sources.

The source that you tend to focus on personally is the code that you and people that you know are writing for this app.

There is the source that comes from your `compileSdkVersion`, representing the Android SDK that you are linking to.

Everything else, generally speaking, is a dependency.

From a pure technical standpoint, dependencies are listed in `build.gradle` files in `dependencies` closures.

Dependency Scopes

One `dependencies` closure appears in the project-level `build.gradle` file, inside of a `buildscript` closure:

```
// Top-level build file where you can add configuration options common to all
sub-projects/modules.

buildscript {

    repositories {
        google()
        jcenter()
    }
    dependencies {
        classpath 'com.android.tools.build:gradle:3.0.0'

        // NOTE: Do not place your application dependencies here; they belong
        // in the individual module build.gradle files
    }
}

allprojects {
    repositories {
        google()
        jcenter()
    }
}

task clean(type: Delete) {
    delete rootProject.buildDir
}
```

Those list places where Gradle plugins come from. You are always depending upon the Android Gradle Plugin, and some other developers publish Gradle plugins that you may elect to use in the future.

However, the `dependencies` closure that we tend to think about the most is the one in our module's `build.gradle` file, such as `app/build.gradle`, such as this closure:

```
dependencies {
    implementation fileTree(dir: 'libs', include: ['*.jar'])
    implementation 'com.android.support.constraint:constraint-layout:1.0.2'
    testImplementation 'junit:junit:4.12'
```

```
    androidTestImplementation 'com.android.support.test:runner:1.0.1'
    androidTestImplementation 'com.android.support.test.espresso:espresso-core:3.0.1'
}
```

Here, there are three types of statements:

- `implementation` says "here is a dependency that I want to use for everything"
- `androidTestImplementation` says "here is a dependency that I want to use for instrumentation tests"
- `testImplementation` says "here is a dependency that I want to use for unit testing"

There are other possibilities, and we will be exploring those and the testing-related statements later in this book. For now, we will focus on `implementation` statements.

Depending on a Local JAR

The first of those `implementation` statements is:

```
    implementation fileTree(dir: 'libs', include: ['*.jar'])
```

This pulls in any JAR files that happen to be in the `libs/` directory of this module.

JARs, as you probably know, are libraries containing Java code, as created by standard Java build tools (`javac`, `jar`, etc.). For the first decade-plus of Java's existence, we distributed reusable bits of code in the form of JAR files. You would download a JAR from a Web site, drop it into your project, and through something like this `implementation` statement, say that your project should use the JAR.

In Android, the contents of these JARs are packaged into your APK. And, whatever `public` classes happen to be in those JARs are available to you at compile time.

However, in general, using plain JARs nowadays is considered to be a bad idea. There is no information in a JAR about:

- What version of the library the JAR represents — while this could be part of the filename, files can be renamed far too easily
- What other libraries this JAR requires — at best, you find that out from documentation, then need to hunt down those JARs and see what *they* require, and so on

Instead, nowadays, you should try to use artifacts, rather than bare JAR files.

What's an Artifact?

An artifact is usually represented in the form of two files:

- The actual content, such as a JAR
- A metadata file, paired with the JAR, that has information about "transitive dependencies" (i.e., the other artifacts that this artifact depends upon)

Artifacts and Repositories

Artifacts are housed in artifact repositories. Those repositories not only contain the artifacts, but they organize the artifacts for easy access. This includes organizing them by version, so you can request a specific version of an artifact and get it, instead of an older (or possibly newer) version of that same artifact.

Some artifact repositories are public. A typical Android project will use two such repositories:

- JCenter, a popular place for open source artifacts
- Google's repository, for things like the Android Gradle Plugin

There are other general-purpose artifact repositories, such as Maven Central or jitpack.io. There are specialty repositories, such as the one used by the author of this book for his artifacts. And there can be private repositories, such as ones used by organizations for their own private artifacts, used by their private projects.

Major Library Families from Google

Beyond what strictly is part of the Android SDK, Google publishes a lot of libraries that developers can opt into by declaring them as dependencies.

These include:

- The Android Support Library, which is the original and largest collection of support code that Google publishes, and which will be used frequently throughout the remainder of this book

- The `ConstraintLayout` library, which we will explore in an upcoming chapter
- The Architecture Components, which are covered in *Android's Architecture Components*, a companion volume to this book by the same author
- The data binding library, which we will explore in an upcoming chapter
- The testing support library, which contains several classes that we will examine in the chapters on app testing
- The Play Services SDK, which will we cover briefly later in the book

Requesting Dependencies

With all that as background, let's explore a bit more about how those `implementation` statements are working and how you can add your own for other dependencies that you may want to use.

Find What You Need

First, you need to identify the dependencies that address whatever problems you need to solve.

Many dependencies will be covered in this book. Yet more are covered in the aforementioned *Android's Architecture Components* book. A few more are in the developer documentation.

The biggest catalog of open source dependencies is the Android Arsenal. Here you can browse and search for dependencies. Each listing will contain links to where you can find out more about that particular library, typically in the form of a GitHub repository.

Configure the Repositories

If you are using one of Google's libraries, a project created in Android Studio 3.0+ should be set up with the proper artifact repository already. Your project also comes pre-configured to pull from JCenter, where many open source libraries are from. As a result, for the vast majority of libraries, you do not need to configure an additional artifact repository.

But, sometimes you do.

For example, the author of this book has published a number of open source libraries, collectively referred to as the CommonsWare Android Components (CWAC). They are published in the author's own artifact repository. When you visit the GitHub repository for one of these libraries, you will see that in the installation instructions, it has a sample `repositories` closure:

```
repositories {
    maven {
        url "https://s3.amazonaws.com/repo.commonsware.com"
    }
}
```

You can do one of two things:

1. Add that `maven {}` closure to the `repositories` closure in the `allprojects` closure in your top-level `build.gradle` file
2. Add the entire sample `repositories` closure to your module's `build.gradle` file

Either of these will make this artifact repository available to you for that module. The first approach makes it available for *all* modules in your app, which may become useful if later you create a library module.

So, when you review the documentation for a dependency, it should indicate what artifact repository to use, and you need to ensure that you are set up to use that repository.

Identify the Dependencies and Versions

Each artifact has an identifier made up of three pieces: a group ID, an artifact ID within the group, and a version number.

```
dependencies {
    implementation fileTree(dir: 'libs', include: ['*.jar'])
    implementation 'com.android.support.constraint:constraint-layout:1.0.2'
    testImplementation 'junit:junit:4.12'
    androidTestImplementation 'com.android.support.test:runner:1.0.1'
    androidTestImplementation 'com.android.support.test.espresso:espresso-core:3.0.1'
}
```

The first `implementation` statement shown above pulls in bare JARs located in your project's filesystem. The remaining statements in this `dependencies` closure

represent artifacts. The three ones that begin with `com.android` are from Google, while the one that starts with `junit` is an open source testing library called JUnit.

You will see that all four of those artifacts have the three-part identifier:

- the group ID (e.g., `com.android.support.constraint`)
- the artifact ID (e.g., `constrant-layout`)
- the version number (e.g., `1.0.2`)

Technically, the version number can contain wildcards. For example, while `1.0.2` indicates a specific version, `1.0.+` says "pick the latest among all versions that start with `1.0`". This is convenient for getting patches, but it means that on some random day, all of a sudden, you are using a new version of the library, and that might cause problems. Typically, we do not use wildcards, but instead just keep tabs on when the artifacts get new versions. Android Studio will help with this, highlighting artifacts that have newer versions available.

Add the Dependencies

Then, you just need to add the appropriate `implementation` lines for whatever dependencies that you wish to add. So, for example, if you wanted to add the CWAC-NetSecurity library to your project, in addition to adding that CWAC repository to your repositories list, you could add:

```
implementation 'com.commonsware.cwac:netsecurity:0.4.4'
```

to your `dependencies` closure.

Note that many libraries showing sample code for adding them to your `build.gradle` file will show a slightly different syntax:

```
compile 'com.commonsware.cwac:netsecurity:0.4.4'
```

That is because Android Studio 3.0 and Gradle 4.1 switched to a new syntax for specifying dependencies. `compile` was replaced by `implementation`. If you use `compile`, your Gradle build script will still work... for now. Eventually, support for `compile` will be dropped, and so you should aim to use `implementation` instead of `compile` going forward.

Also note that some of the sample projects in this book will use `compile`, as the book slowly adjusts to the new syntax.

We will see lots of `dependencies` closures throughout the rest of this book, showing different artifacts that we can depend upon.

The Android Support Library

The Android Support Library is a series of artifacts distributed by Google, containing general-purpose classes (in JARs and Android library projects) that are not part of the Android SDK, but are available to Android developers.

What's In There?

You can roughly divide the contents of the Android Support Library into two major areas:

1. "Backports" of capabilities added to newer versions of Android and the Android SDK, so they can be used on older devices as well. By using the backported classes, you can get the same abilities on a wider range of devices than you could if you only used the classes in the Android SDK.
2. New widgets, containers, or other classes that are not going to be in the Android SDK (for ill-defined reasons) but that Google wishes to make available for Android developers.

Example artifacts of the Android Support Library include:

- `appcompat-v7`, which is a backport of the action bar, a concept that we will discuss in an upcoming chapter
- `recyclerview-v7`, which is the home of the `RecyclerView` widget that serves as an alternative to `ListView` and `GridView`
- `support-compat`, with compatibility classes to make it easier to support both old versions of Android and new ones
- `support-core-ui`, offering some widgets and containers, such as `ViewPager`
- `support-fragment`, providing a backport of fragments

About the Names

What this book refers to as the "Android Support Library" has many names.

It was originally referred to as the Android Compatibility Library, at a time when it only contained backports. Once Google started adding in things that were not strictly related to "compatibility", they started changing the name to try to be more

generic. Right now, "Android Support" seems to be fairly consistent, either used standalone or in the form of "Android Support Library" or "Android Support Libraries".

About the -v Suffixes

Some artifact names have version suffixes, like `recyclerview-v7`. Others do not, such as `support-fragment`. The `-v7` naming convention used to indicate the `minSdkVersion` supported by that artifact. Originally, `recyclerview-v7` worked back to API Level 7 and did not support older versions of Android than that.

However, that was a fairly inflexible system. Not only has Google abandoned it for newer artifacts, but the actual value no longer has meaning. In particular, the entire Android Support Library only supports back to API Level 15 at this point, with a few exceptions that do not go back even that far.

Getting It

Google is now distributing its libraries via their own Maven-style artifact repository. With Android Studio 3.0, this repository is what you get from that `google()` statement in the `repositories` closures.

For most libraries for most versions that you are likely to encounter, the `google()` repository will have what you need. You can visit the Google Maven Repository site to see what artifacts and versions are served from it.

Originally, these libraries were distributed via the Android Support Repository, one that you would have on your own hard drive, downloaded via the SDK Manager.

Choosing a Version

Typically, and historically, developers would take a three-tier approach towards the version of these libraries:

- When starting a new project, developers would use the then-current edition of the libraries, along with the latest `compileSdkVersion`
- When a new patch release to the libraries was released — for example, from `25.3.0` to `25.3.1` — developers would update to that version, as usually the patches fix bugs

- When it came time for the project to move to a new `compileSdkVersion`, developers would move to the matching major version of the libraries (e.g., when moving to `compileSdkVersion 26`, switch to version `26.1.0` of the libraries)

That is still a fine pattern... if your `minSdkVersion` is 15 or higher. For many developers, that will be the case.

However, if you are aiming to still support Android 2.x devices, you have a problem: starting with the v26 edition of the Support Library, the oldest version of Android supported by the libraries is Android 4.0.3, API Level 15. This means that you will need to stick with `compileSdkVersion 25` and the v25 edition of the Support Library until such time as you either:

- Remove all ties to the Support Library, or
- Raise your `minSdkVersion` to 15 or higher

Attaching It To Your Project

You can add references to the Android Support Library's libraries — whether those libraries are simple JARs or Android library projects — via a few lines in your `dependencies` closure, referencing the artifacts from the Android Support Repository.

Here are the `implementation` statements for many artifacts in the Android Support Library:

```
implementation 'com.android.support:appcompat-v7:27.0.2'
implementation 'com.android.support:cardview-v7:27.0.2'
implementation 'com.android.support:design:27.0.2'
implementation 'com.android.support:exifinterface:27.0.2'
implementation 'com.android.support:gridlayout-v7:27.0.2'
implementation 'com.android.support:leanback-v17:27.0.2'
implementation 'com.android.support:mediarouter-v7:27.0.2'
implementation 'com.android.support:palette-v7:27.0.2'
implementation 'com.android.support:percent:27.0.2'
implementation 'com.android.support:recyclerview-v7:27.0.2'
implementation 'com.android.support:support-annotations:27.0.2'
```

Also, while you *could* add all of these to your project, that is not necessary. Only attach dependencies for libraries that you are actually using. Having unused libraries

in your project just increases your APK size for no good reason. Hence, most projects will have only a subset of the aforementioned lines.

Note that, in general, when using the Android Support libraries, you should set your `compileSdkVersion` and `targetSdkVersion` to be the same as the major version of the library. So, for a `26.1.0` version of the library, your `compileSdkVersion` should be `26`.

Tutorial #6 - Adding a Library

We will want to use some third-party libraries in our project, to ease development of the app:

- the Android Support library, specifically its `android-support-v13` JAR
- greenrobot's EventBus, for communication between various pieces of our app
- Google's Gson parser of JSON data
- Square's Retrofit, including its Gson-based converter code, for retrieving JSON data from Web services,
- Square's OkHttp, for general HTTP requests, like downloading a ZIP archive
- the CWAC-Security library, by the author of this book, which contains some code for securely unpacking a ZIP archive
- an implementation of tabs

Right now, we will just focus on arranging for our project to be able to use the libraries. Later in the book, we will actually put the libraries to use.

This is a continuation of the work we did in the previous tutorial.

You can find the results of the previous tutorial and the results of this tutorial in the book's GitHub repository.

Step #1: Getting Rid of Existing Cruft

If you look at the `app/build.gradle` file, you will see that we already have some dependencies:

```
dependencies {
    implementation fileTree(dir: 'libs', include: ['*.jar'])
```

```
    androidTestImplementation('com.android.support.test.espresso:espresso-core:2.2.2', {
        exclude group: 'com.android.support', module: 'support-annotations'
    })
    testImplementation 'junit:junit:4.12'
}
```

(from EmPubLite-AndroidStudio/T5-Layout/EmPubLite/app/build.gradle)

These dependencies are the sort of thing that gets added automatically to your project by the new-project wizard. While you imported your starter project, rather than creating it from scratch, the starter project has these dependencies because *it* was created from the new-project wizard.

However, we are not going to use any of those dependencies:

- The `implementation fileTree()` line pulls in bare JAR files from the `libs/` directory, and we will not be using bare JAR files
- The other statements pull in dependencies for testing, and while testing is a fine thing to do, these tutorials do not have you write any test cases

However, not only does the new-project wizard generate dependencies like these for us, but it also code-generates some do-nothing test code that depends upon these dependencies. So, we will leave those two test dependencies alone, as it is simpler to ignore them than it is to clean that part up.

But go ahead and delete the `implementation fileTree` statement, leaving you with

```
dependencies {

androidTestImplementation('com.android.support.test.espresso:espresso-core:2.2.2', {
        exclude group: 'com.android.support', module: 'support-annotations'
    })
    testImplementation 'junit:junit:4.12'
}
```

You may get a yellow banner at the top of the editor, indicating that a “project sync” is requested. Ignore that for the moment, as we will be making more changes to this file.

Step #2: Requesting New Dependencies

Many of the dependencies we are going to set up now are available from JCenter, and our project is already set up to pull from there. However, the CWAC-Security library is not, and so we will need to teach Gradle how to find that library.

To do that, add the following code to your `app/build.gradle` file, above the `dependencies` closure:

```
repositories {
    maven {
        url "https://s3.amazonaws.com/repo.commonsware.com"
    }
}
```

(from EmPubLite-AndroidStudio/T6-Library/EmPubLite/app/build.gradle)

Then, add seven more lines to the `dependencies` closure, identifying the libraries that we need:

```
dependencies {
    androidTestImplementation('com.android.support.test.espresso:espresso-core:2.2.2', {
        exclude group: 'com.android.support', module: 'support-annotations'
    })
    testImplementation 'junit:junit:4.12'
    implementation 'org.greenrobot:eventbus:3.0.0'
    implementation 'com.google.code.gson:gson:2.8.0'
    implementation 'com.squareup.retrofit2:converter-gson:2.1.0'
    implementation 'com.squareup.okhttp3:okhttp:3.4.1'
    implementation 'com.commonsware.cwac:security:0.8.0'
    implementation 'com.android.support:support-v13:25.3.0'
    implementation 'io.karim:materialtabs:2.0.5'
}
```

(from EmPubLite-AndroidStudio/T6-Library/EmPubLite/app/build.gradle)

At this point, your `app/build.gradle` file should look something like:

```
apply plugin: 'com.android.application'

android {
    compileSdkVersion 25
    buildToolsVersion '26.0.2'
    defaultConfig {
        applicationId "com.commonsware.empublite"
        minSdkVersion 15
        targetSdkVersion 25
        versionCode 1
        versionName "1.0"
        testInstrumentationRunner "android.support.test.runner.AndroidJUnitRunner"
    }
    buildTypes {
        release {
            minifyEnabled false
            proguardFiles getDefaultProguardFile('proguard-android.txt'), 'proguard-rules.pro'
        }
    }
}

repositories {
```

```
    maven {
        url "https://s3.amazonaws.com/repo.commonsware.com"
    }
}

dependencies {
    androidTestImplementation('com.android.support.test.espresso:espresso-core:2.2.2', {
        exclude group: 'com.android.support', module: 'support-annotations'
    })
    testImplementation 'junit:junit:4.12'
    implementation 'org.greenrobot:eventbus:3.0.0'
    implementation 'com.google.code.gson:gson:2.8.0'
    implementation 'com.squareup.retrofit2:converter-gson:2.1.0'
    implementation 'com.squareup.okhttp3:okhttp:3.4.1'
    implementation 'com.commonsware.cwac:security:0.8.0'
    implementation 'com.android.support:support-v13:25.3.0'
    implementation 'io.karim:materialtabs:2.0.5'
}
```

(from EmPubLite-AndroidStudio/T6-Library/EmPubLite/app/build.gradle)

If that "project sync" yellow banner is at the top of the editor, click the "Sync Now" link in that banner to synchronize the `*.iml` files with the changes you made to this `build.gradle` file. If it is not there, choose Tools > Android > Sync Project with Gradle Files to force that resync.

In Our Next Episode…

… we will configure the action bar on our tutorial project.

Introducing ConstraintLayout

In 2016, Google released a new container class, `ConstraintLayout`, that it hopes will become popular among Android developers as an alternative to `LinearLayout` and `RelativeLayout`. Certainly, Google is going to "pull out all the stops" to convince developers to use `ConstraintLayout`, such as having it be used in many of the activity templates employed by Android Studio's new-activity wizard.

`ConstraintLayout` is useful, but it is not required for Android app development, any more than `LinearLayout` and `RelativeLayout` are. And, since `ConstraintLayout` is a library, it adds ~100KB to the size of your Android app. Whether it is worth that extra space is for you to decide.

Why Another Container?

`LinearLayout`, `RelativeLayout`, and (to a lesser extent) `TableLayout` have served as the backbone of most Android apps. Previous attempts to provide a new foundation container class — such as `GridLayout` – have not proven to be particularly popular.

So, why did Google bother creating `ConstraintLayout`?

Drag-and-Drop GUI Builders

Google would like everyone to use Android Studio, and in particular for everyone to use Android Studio's drag-and-drop GUI builder.

How well a drag-and-drop GUI builder works depends a lot on how the rules for laying out a UI get defined. With drag-and-drop gestures, the developer is only providing you with X/Y coordinates of a widget, based on where the developer

releases the mouse button and completes the drop. It is up to the GUI builder to determine what that really means in terms of layout rules.

With `LinearLayout`, adding a widget is fairly easy:

- If the developer drops the widget between two existing children of a `LinearLayout`, put the new widget in between the existing ones
- Otherwise, add the widget to the end of the `LinearLayout` where the developer dropped it

`TableLayout` is a bit more involved but still not that bad, as we have decades of experience of working with spreadsheets to know about inserting rows and columns into a grid-like structure.

`RelativeLayout`, though, was difficult for a GUI builder to handle. Often, the Android Studio GUI builder (and its predecessor in Eclipse) would misinterpret the developers wishes. Sometimes, the rules the developer wanted to express were simply unavailable through pure drag-and-drop operations. As a result, developers had to dive into the XML to get anything done. Being able to read layout XML is important – otherwise, books like this would be unusable. However, forcing developers to write the XML defeated the purpose of the GUI builder.

`ConstraintLayout` was created with GUI building in mind, to make it a bit easier to infer the right rules based upon where the developer happens to drop a widget.

Performance

`RelativeLayout`, `LinearLayout` with `android:layout_weight`, and `TableLayout` with `android:stretchColumns`/`android:shrinkColumns`, all require two passes over their children to determine final sizes and positions. For example, with a weighted `LinearLayout`, you need to make one pass to calculate the directly-expressed sizes (e.g., `android:layout_height`), followed by a second pass to allocate the remaining space according to the weight.

This gets exacerbated by the fact that changing the details of a widget often causes the sizes to have to be recomputed. Suppose that you change the text in a `TextView` with `android:layout_width="wrap_content"`. Changing the text changes the horizontal space taken up by that text. So, the `TextView` winds up telling its container “hey, please recompute the sizes and positions”, as the larger `TextView` might now cause shifts in other children of the container. Depending on how the

container itself is sized, it might need to tell *its* container to recompute the sizes and positions.

Cascading upward to have parents re-size/re-position their children gets very expensive for deep hierarchies, where we have containers holding containers holding containers holding containers and so on. One change in text of a `TextView` might cause that whole hierarchy to go through re-size/re-position work.

All else being equal:

- Deeper view hierarchies are slower to render than are shallower ones
- View hierarchies where parents need two passes to size and position their children are slower to render than are hierarchies where only one pass is needed

`ConstraintLayout` is being designed with performance in mind, trying to eliminate as many two-pass scenarios as possible and by trying to eliminate the need for deeply-nested view hierarchies. Right now, `ConstraintLayout` performance is not that great. However, it is a focus area and should improve over time.

Comparing with the Classics

Stylistically, `ConstraintLayout` most closely resembles `RelativeLayout`. As with `RelativeLayout`, you can anchor widgets to other widgets inside the `ConstraintLayout` or to the boundaries of the `ConstraintLayout` itself.

Many structures that can be implemented using `LinearLayout` but not `RelativeLayout` — such as allocating widget sizes based on weights – can be handled by `ConstraintLayout`. `ConstraintLayout` is designed to handle such conditional sizing without requiring two passes through its children to determine those sizes.

However, `TableLayout` remains distinct. `ConstraintLayout` does not have the notion of columns, let alone sizing those columns based upon their contents and layout rules.

Getting ConstraintLayout

To use `ConstraintLayout`, you do not need to do anything special with your SDK Manager. All that you need to do is to request some version of the

`com.android.support.constraint:constraint-layout` artifact in your `dependencies` closure of your module's `build.gradle` file:

```
dependencies {
  implementation 'com.android.support:support-v13:25.3.1'
  implementation 'com.android.support.constraint:constraint-layout:1.0.2'
}
```

(from Containers/Sampler/app/build.gradle)

For Android Studio 2.2+ users, getting this dependency is similar to the rest of the support libraries. You download the right bits to your development machine using the Android Studio SDK Manager, and the Android Plugin for Gradle then knows where to look for it. However, for inexplicable reasons, `ConstraintLayout` requires downloading two additional SDK Manager items:

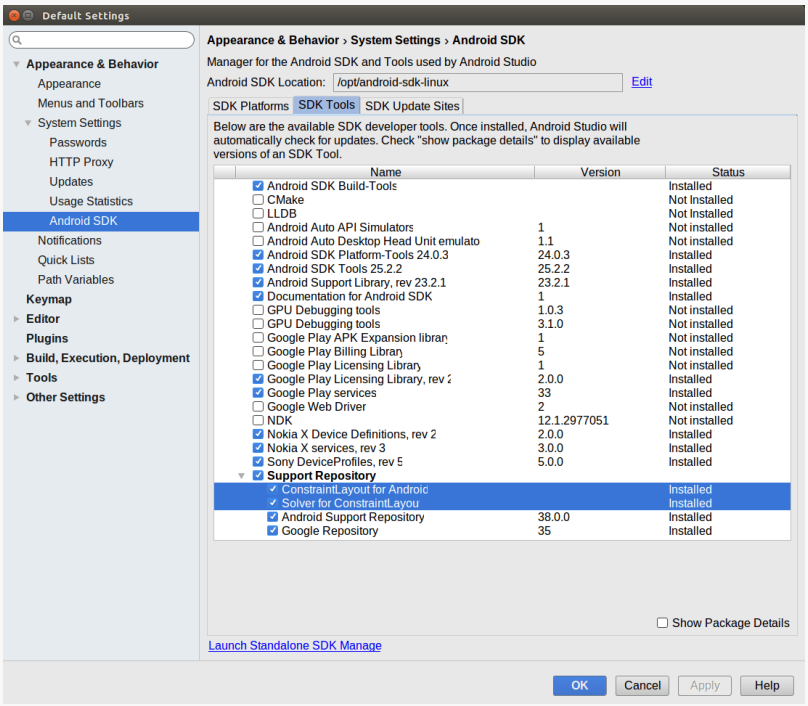

Figure 178: SDK Manager, With ConstraintLayout Items Highlighted

Getting `ConstraintLayout` outside of Android Studio is undocumented and complicated at the present time.

Using Widgets and Containers from Libraries

When you create layout resources using widgets and containers that are part of the main Android SDK, you:

- Use `android:` prefixes for nearly every attribute, and
- Use a bare class name (e.g., `Button`), instead of a fully-qualified class name (e.g., `android.widget.Button`), for nearly every element name

When you use widgets and containers from libraries — including those from the Android Support libraries — you:

- Use a mix of an `android:` and `app:` prefixes for attributes, where the `app:` ones are for attributes that are not part of the main Android SDK
- Use a fully-qualified class name for the element names (e.g., `android.support.constraint.ConstraintLayout`)

That `app:` prefix requires another XML namespace declaration: `xmlns:app="http://schemas.android.com/apk/res-auto"`. Usually, this will be added to your layout resource automatically or via a quick-fix.

When we start reviewing the XML for `ConstraintLayout`, you will see both of these changes come into effect.

Using a ConstraintLayout

Back in the chapter on the classic container classes, we reviewed several layouts from the `Containers/Sampler` sample project. That project also happens to use `ConstraintLayout`, and it has several layouts that demonstrate how `ConstraintLayout` can be used in place of the classic containers. They also serve to illustrate how to use `ConstraintLayout` in general.

Basic Anchoring, Single Axis

In the chapter on classic containers, we had the “bottom-then-top” scenario, with a small `Button` on the bottom, underneath another `Button` that took up all the remaining space:

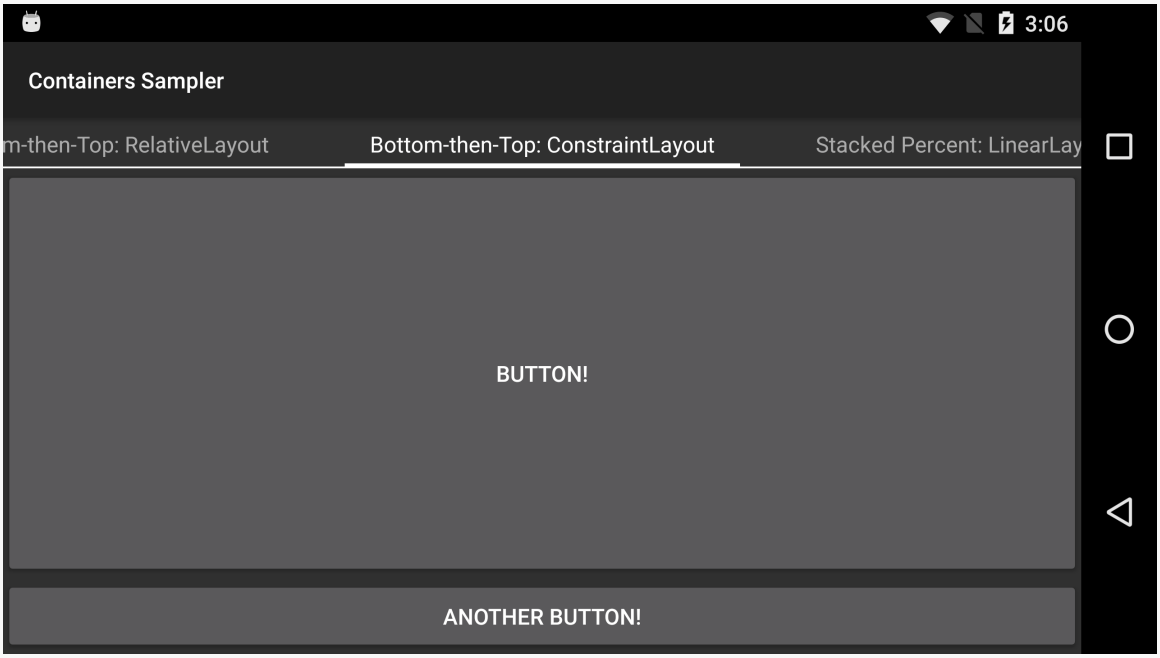

Figure 179: Bottom-then-Top Layout, Using ConstraintLayout

In addition to being able to implement this using `LinearLayout` and using `RelativeLayout`, you can implement this using `ConstraintLayout`. Here, we are setting the sizes and locations of two widgets, but only focusing on a single axis at the moment: the vertical axis.

The XML

The `ConstraintLayout` approach resembles that of the `RelativeLayout` implementation. We use layout rules to tie the bottom `Button` to the bottom of the `ConstraintLayout` and tie the top `Button` between the top of the `ConstraintLayout` and the top of the bottom `Button`:

```
<?xml version="1.0" encoding="utf-8"?>
<android.support.constraint.ConstraintLayout xmlns:android="http://schemas.android.com/apk/res/android"
  xmlns:app="http://schemas.android.com/apk/res-auto"
  android:layout_width="match_parent"
  android:layout_height="match_parent">

  <Button
    android:layout_width="0dp"
    android:layout_height="0dp"
    android:text="@string/button"
    app:layout_constraintBottom_toTopOf="@+id/another_button"
    app:layout_constraintEnd_toEndOf="parent"
    app:layout_constraintStart_toStartOf="parent"
```

```
    app:layout_constraintTop_toTopOf="parent" />

  <Button
    android:id="@id/another_button"
    android:layout_width="0dp"
    android:layout_height="wrap_content"
    android:text="@string/another_button"
    app:layout_constraintBottom_toBottomOf="parent"
    app:layout_constraintEnd_toEndOf="parent"
    app:layout_constraintStart_toStartOf="parent" />
</android.support.constraint.ConstraintLayout>
```

(from Containers/Sampler/app/src/main/res/layout/bottom_then_top_cl.xml)

The bottom `Button` has three `ConstraintLayout` rules, such as `app:layout_constraintBottom_toBottomOf="parent"`. `ConstraintLayout` rules are verbose and a bit odd-looking. It may help to unpack this into pieces:

- `app:` is because `ConstraintLayout` comes from a library, not the Android framework itself
- `layout_` is the standard prefix for rules based upon a widget's container, no different than what we saw with the classic containers
- `constraint` is used in all the `ConstraintLayout`-specific rule attribute names
- `Bottom` indicates what side of the widget we are looking to anchor (in this case, the bottom of the widget)
- `toBottomOf` indicates what side of the target (`parent`) we want to anchor to (in this case, the bottom of the `ConstraintLayout`)

The value associated with the rule attribute is either a widget ID of another child of the same `ConstraintLayout`, or `parent` to indicate the `ConstraintLayout` itself. So, our `Button` is anchored to the bottom of the `ConstraintLayout`, with its natural `wrap_content` height.

The three rules on the bottom `Button` are:

- `app:layout_constraintBottom_toBottomOf="parent"`, to tie the bottom of the `Button` to the bottom of the `ConstraintLayout`
- `app:layout_constraintEnd_toEndOf="parent"`, to tie the end of the `Button` to the end of the `ConstraintLayout`
- `app:layout_constraintStart_toStartOf="parent"`, to tie the start of the `Button` to the start of the `ConstraintLayout`

Our top `Button` has four `ConstraintLayout` rule attributes:

- `app:layout_constraintBottom_toTopOf="@+id/another_button"` anchors the bottom of this `Button` to the top of the bottom `Button`, based upon the ID of the bottom `Button`
- `app:layout_constraintTop_toTopOf="parent"` anchors the top of the top `Button` to the top of the `ConstraintLayout`
- `app:layout_constraintEnd_toEndOf="parent"` anchors the end of the top `Button` to the end of the `ConstraintLayout`
- `app:layout_constraintStart_toStartOf="parent"` anchors the start of the top `Button` to the start of the `ConstraintLayout`

Sizes of widgets also play a role here. The height of the bottom `Button` is `wrap_content`, so it will be its natural height. The height of the top `Button` is `0dp`, indicating that we want to stretch it between anchor points established by rules. The width of both buttons is also `0dp`, indicating that we want those buttons to be stretched between anchor points along the horizontal axis.

Now, you might wonder why we do not just set the width of the buttons to `match_parent` and skip the "start" and "end" rules. In an ideal world, this is what we would do. The developers of `ConstraintLayout` have other ideas, and those ideas include making `match_parent` useless. If you try to use `match_parent`, the actual width that you get will vary by circumstance and rarely actually fill the available space. So, we are stuck with the `0dp`-and-anchor-rules approach.

The Android Studio Graphical Layout Editor

As with other containers, you can create a new layout resource with a `ConstraintLayout` as the root, by right-clicking over a `layout` resource directory, choosing New > "Layout resource file" from the context menu, and typing in `android.support.constraint.ConstraintLayout` for the root element. Fortunately, auto-complete on the "Root element" field allows you to just start typing `ConstraintLayout`, then choose the fully-qualified class name from the drop-down list.

If you drag a widget into the `ConstraintLayout` and drop it in an arbitrary spot, what you get at design time will be different than what you get when you run the app. In the graphical layout editor, the `Button` shows up where you drop it:

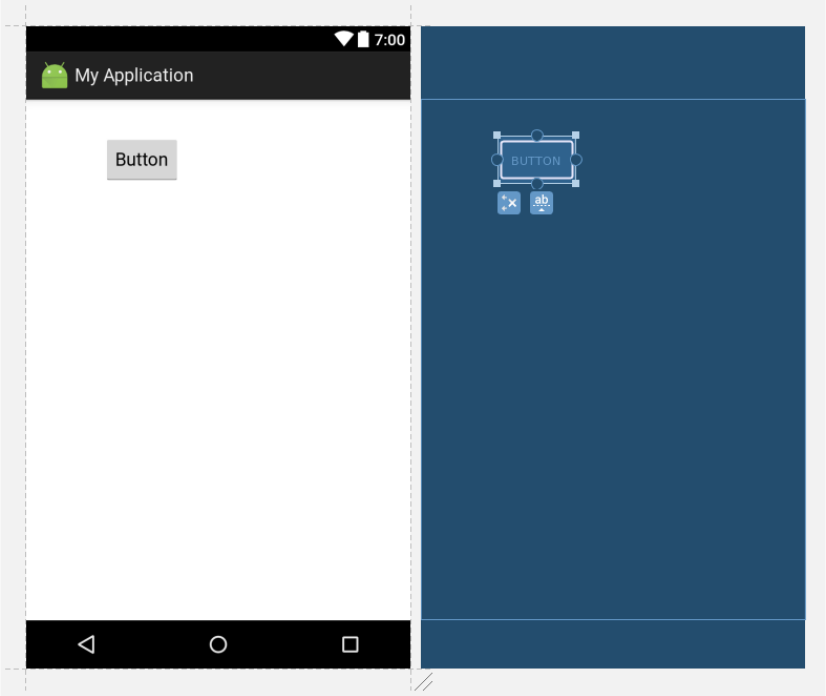

Figure 180: ConstraintLayout, With Dragged-In Button

However, if you look at the XML that was generated, you will see that the `Button` has no constraints. It *does* have a pair of attributes with the `tools:` prefix: `tools:layout_editor_absoluteX` and `tools:layout_editor_absoluteY`:

```
<?xml version="1.0" encoding="utf-8"?>
<android.support.constraint.ConstraintLayout
  xmlns:android="http://schemas.android.com/apk/res/android"
  xmlns:tools="http://schemas.android.com/tools"
  android:layout_width="match_parent"
  android:layout_height="match_parent">

  <Button
    android:id="@+id/button9"
    android:layout_width="wrap_content"
    android:layout_height="wrap_content"
    android:text="Button"
    tools:layout_editor_absoluteX="77dp"
    tools:layout_editor_absoluteY="36dp" />
</android.support.constraint.ConstraintLayout>
```

Attributes in the `tools:` namespace are suggestions to the development tools and have no impact on the behavior of your app when it runs. In this case, Android

Studio remembers the upper-left corner of where you dropped the `Button`. But, as a warning on the `Button` in the layout editor will tell you, a `Button` without constraints will wind up at coordinate `(0,0)` at runtime (basically, upper-left for LTR languages and upper-right for RTL languages).

Dragging in a widget is insufficient. You also need to use the graphical layout editor to define the constraints.

If you click on a widget that you dragged into the `ConstraintLayout`, the blueprint view will show squares on the corners and circles centered on the edges, plus a couple of bubbles beneath it:

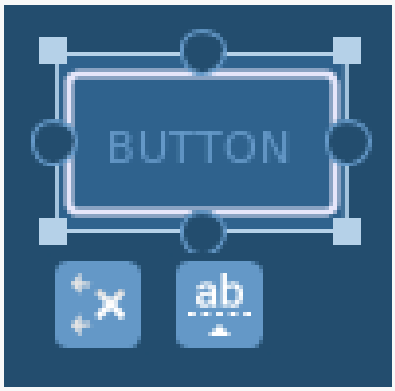

Figure 181: Blueprint View, Showing Annotated Widget

The squares are resize handles. Most likely, you have seen this pattern before, whether in IDEs, drawing tools, or other programs. You would use this resizing approach if you wanted a fixed size for the widget. Later switching to using dimension resources, rather than hard-coded values, for the size values would be a good idea. You can also change the width and height through the Attributes pane, as with widgets inside of other sorts of containers.

The circles are more important, as they allow you to define the constraints, by dragging a circle to some anchor point:

Figure 182: Blueprint View, Showing Constraint Being Created

To create the bottom `Button` from the layout shown in the previous section, you would set its width to be `0dp`, then use the circles to establish the three constraints, on the bottom, start, and end:

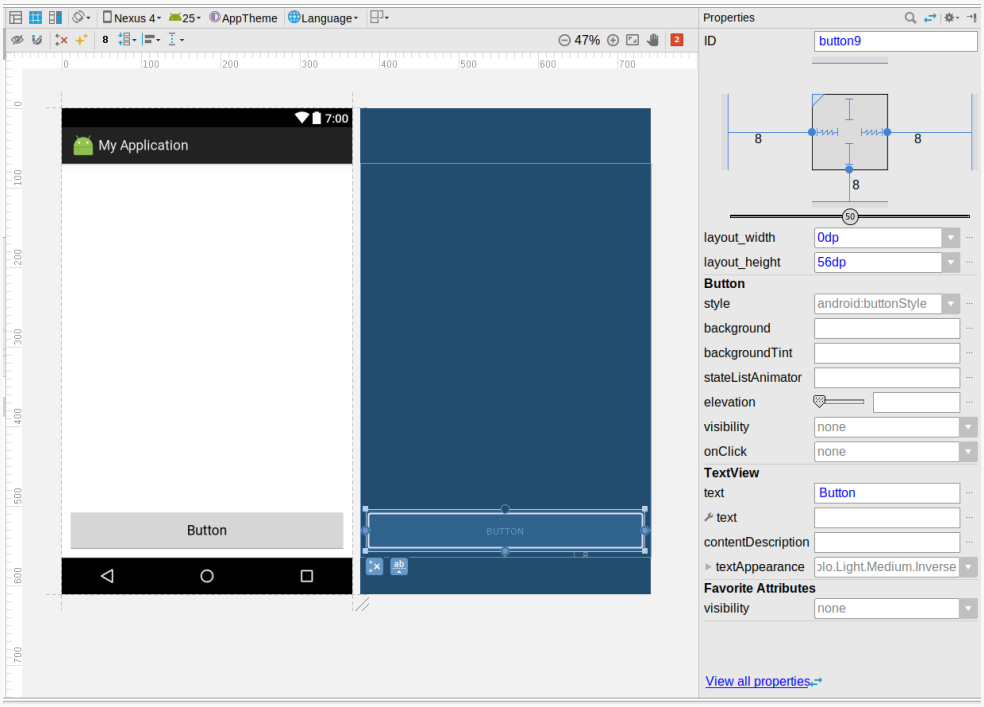

Figure 183: Blueprint View, Showing Three Constraints on Bottom Button

To create the top `Button`, you would drag another `Button` into the `ConstraintLayout`, set its width and height to `0dp`, then set up the four constraints, one on each side. In the case of the constraint starting from the bottom-edge circle of the top `Button`, you would drag it to the top edge of the bottom `Button` to tie those widgets together:

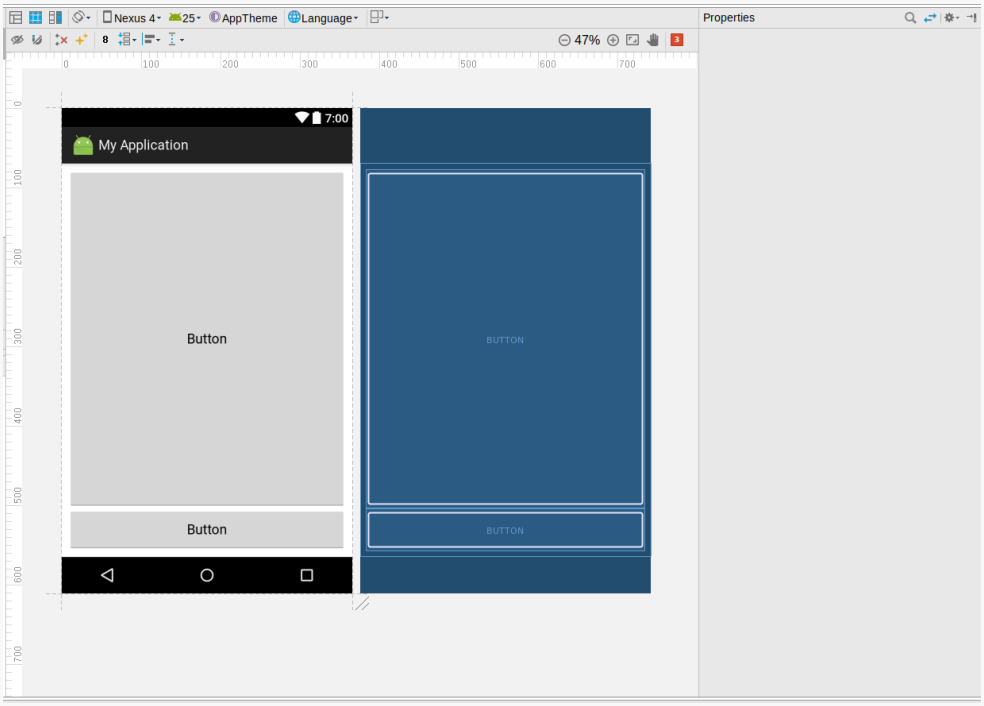

Figure 184: Preview and Blueprint View, Showing Two Buttons

When you click on a widget inside a `ConstraintLayout`, the Attributes pane has a strange-looking control above the regular properties:

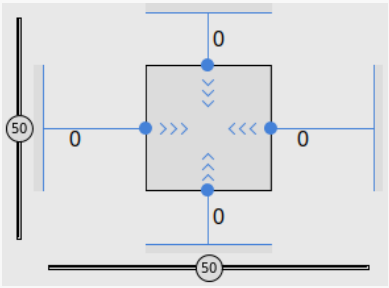

Figure 185: Constraint Configuration Thingy

This allows you to manage some aspects of the constraints. For example, the four 0 values shown in that image turn into comboboxes when clicked, and their values form the margins on that side of the widget.

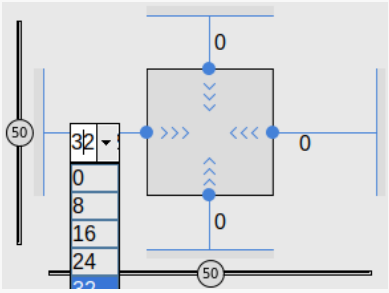

Figure 186: Constraint Configuration Thingy, Showing Margin Combobox

The four sets of chevrons indicate that the sizing rules are `wrap_content` for both the `layout_width` and `layout_height`. Clicking one of the chevrons will toggle between three states for that axis:

- `wrap_content`, indicated by chevrons
- a fixed width, indicated by a sizing bar

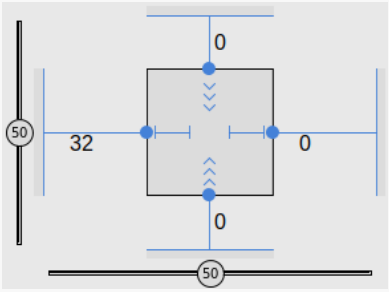

Figure 187: Constraint Configuration Thingy, Showing Fixed Horizontal Sizing

- `0dp`, for stretching the size to the available space, indicated by a sawtooth line

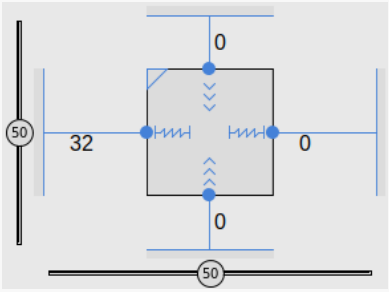

Figure 188: Constraint Configuration Thingy, Showing "Match Constraints" Sizing

Basic Anchoring, Dual Axis

Of course, `ConstraintLayout` can control sizing and positioning horizontally as well as vertically. The "URL dialog" scenario from the chapter on classic containers can be implemented easily enough using a `ConstraintLayout`:

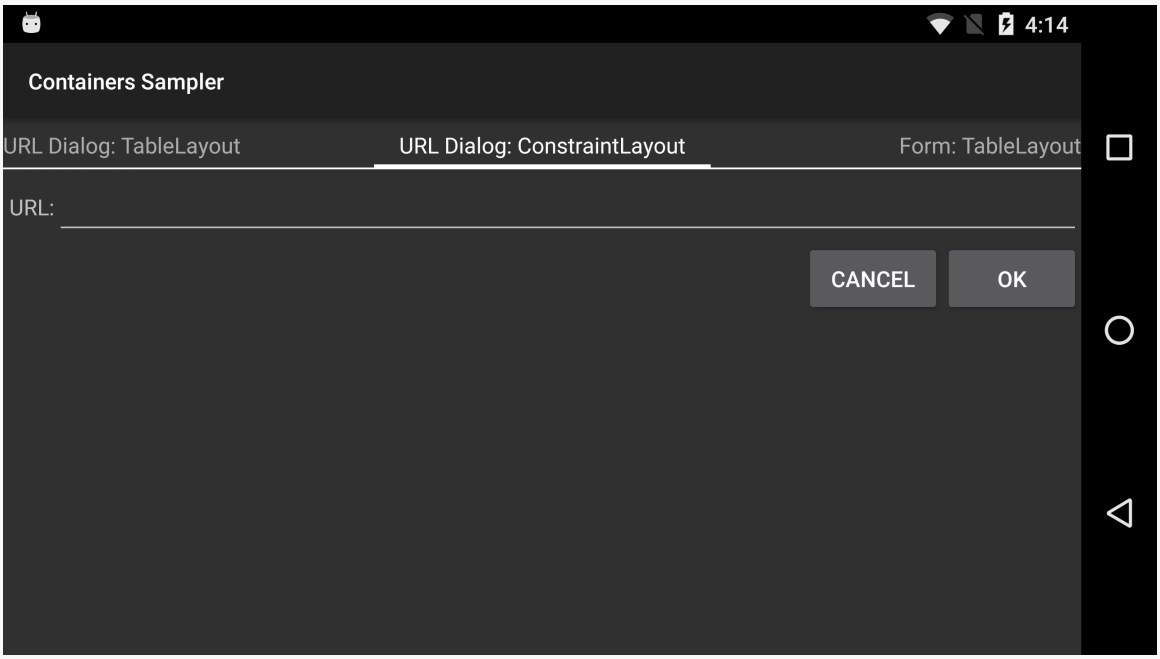

Figure 189: URL Dialog Layout, Using ConstraintLayout

Once again, the `ConstraintLayout` version resembles a more-complex representation of the `RelativeLayout` version:

```
<?xml version="1.0" encoding="utf-8"?>
<android.support.constraint.ConstraintLayout
  xmlns:android="http://schemas.android.com/apk/res/android"
  xmlns:app="http://schemas.android.com/apk/res-auto"
  android:layout_width="match_parent"
  android:layout_height="wrap_content">

  <TextView
    android:id="@+id/label"
    android:layout_width="wrap_content"
    android:layout_height="wrap_content"
    android:layout_marginLeft="4dip"
    android:layout_marginStart="4dip"
    android:text="@string/url"
```

```
    app:layout_constraintBaseline_toBaselineOf="@+id/entry"
    app:layout_constraintStart_toStartOf="parent" />

  <EditText
    android:id="@id/entry"
    android:layout_width="0dp"
    android:layout_height="wrap_content"
    android:inputType="text"
    app:layout_constraintEnd_toEndOf="parent"
    app:layout_constraintStart_toEndOf="@id/label"
    app:layout_constraintTop_toTopOf="parent" />

  <Button
    android:id="@+id/ok"
    android:layout_width="wrap_content"
    android:layout_height="wrap_content"
    android:text="@string/ok"
    app:layout_constraintEnd_toEndOf="@id/entry"
    app:layout_constraintTop_toBottomOf="@id/entry" />

  <Button
    android:id="@+id/cancel"
    android:layout_width="wrap_content"
    android:layout_height="wrap_content"
    android:text="@string/cancel"
    app:layout_constraintEnd_toStartOf="@id/ok"
    app:layout_constraintTop_toTopOf="@id/ok" />

</android.support.constraint.ConstraintLayout>
```

(from Containers/Sampler/app/src/main/res/layout/url_dialog_cl.xml)

The `TextView` uses `app:layout_constraintStart_toStartOf="parent"` to say that its starting edge aligns with the starting edge of the `ConstraintLayout`. It also uses `app:layout_constraintBaseline_toBaselineOf="@+id/entry"` to have its baseline align with the baseline of the `EditText`.

The `EditText` uses:

- `app:layout_constraintStart_toEndOf="@id/label"` to have its starting edge align with the ending edge of the `TextView`
- `app:layout_constraintEnd_toEndOf="parent"` and `android:layout_width="0dp"` to have its ending edge align with the ending edge of the `ConstraintLayout` (and, therefore, span to fill the remaining space in the row)

- `app:layout_constraintTop_toTopOf="parent"` to have its top edge align with the top edge of the `ConstraintLayout`

The "OK" `Button` has its ending edge align with that of the `EditText` (`app:layout_constraintEnd_toEndOf="@id/entry"`) and has its top edge align with the bottom edge of the `EditText` (`app:layout_constraintTop_toBottomOf="@id/entry"`)

The "Cancel" `Button` has its ending edge align with the starting edge of the "OK" `Button` (`app:layout_constraintEnd_toStartOf="@id/ok"`) and has its top edge align with the top edge of the "OK" `Button` (`app:layout_constraintTop_toTopOf="@id/ok"`)

Note that to create a baseline via drag-and-drop, you need to:

- Click on the "ab" icon in the blueprint below the widget whose baseline should be constrained. This should enable a "lozenge" drag handle underneath the text in the widget:

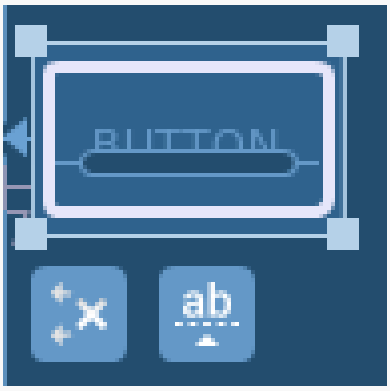

Figure 190: Baseline Constraint Enabled

- Start dragging that "lozenge" shape, which will enable similar shapes on other text-based widgets
- Drag the connection line to the "lozenge" in the other widget, to have the first widget's baseline depend upon the second widget's baseline:

Figure 191: Baseline Constraint Established

Guidelines

Where `ConstraintLayout` starts to depart from the classic containers is with its use of `Guideline` widgets.

Guidelines in graphics editors help in drawing operations. For example, in an SVG editor like Inkscape, you can "snap" shapes to align along a guideline. The guideline itself does not appear in the output; it is merely something used at drawing time to aid in drawing.

A `Guideline` serves a similar role with `ConstraintLayout`. A `Guideline` is not rendered as part of our UI. It does, however, allow us to anchor widgets inside the `ConstraintLayout` to the `Guideline`, just as we can anchor those widgets to other widgets or to the `ConstraintLayout` itself. And, as the name suggests, a `Guideline` is part of our GUI builder as well, to allow you to visually place the `Guideline` and connect widgets to that `Guideline`.

For example, in the chapter on the classic containers, we looked at how you could use weights with a `LinearLayout` to allocate size on a percentage basis. However, we did not replicate that structure with `RelativeLayout`, as `RelativeLayout` on its own has no way of working with percentages. `ConstraintLayout` on its own would also be incapable of handling this scenario... but with the use of a pair of `Guideline` widgets, it can:

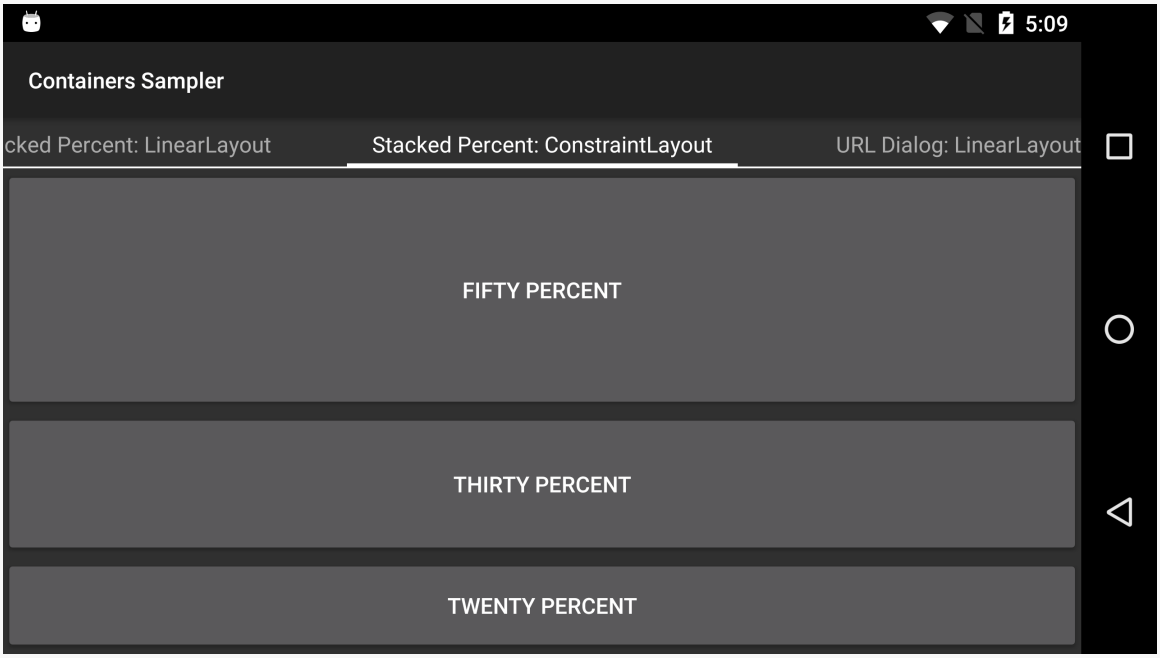

Figure 192: Stacked-Percent Layout, Using ConstraintLayout

And, as it turns out, `ConstraintLayout` does not require two passes through its children to attain this structure, the way that `LinearLayout` does when weights are applied.

The cost is that this layout is significantly more complex than is its `LinearLayout` counterpart:

```
<?xml version="1.0" encoding="utf-8"?>
<android.support.constraint.ConstraintLayout
  xmlns:android="http://schemas.android.com/apk/res/android"
  xmlns:app="http://schemas.android.com/apk/res-auto"
  android:layout_width="match_parent"
  android:layout_height="match_parent">

  <android.support.constraint.Guideline
    android:id="@+id/guideline_50"
    android:layout_width="wrap_content"
    android:layout_height="wrap_content"
    android:orientation="horizontal"
    app:layout_constraintGuide_percent=".50" />

  <android.support.constraint.Guideline
    android:id="@+id/guideline_80"
    android:layout_width="wrap_content"
```

```
    android:layout_height="wrap_content"
    android:orientation="horizontal"
    app:layout_constraintGuide_percent=".80" />

  <Button
    android:layout_width="0dp"
    android:layout_height="0dp"
    android:text="@string/fifty_percent"

    app:layout_constraintBottom_toTopOf="@id/guideline_50"
    app:layout_constraintEnd_toEndOf="parent"
    app:layout_constraintStart_toStartOf="parent"
    app:layout_constraintTop_toTopOf="parent" />

  <Button
    android:layout_width="0dp"
    android:layout_height="0dp"
    android:text="@string/thirty_percent"

    app:layout_constraintBottom_toTopOf="@id/guideline_80"
    app:layout_constraintEnd_toEndOf="parent"
    app:layout_constraintStart_toStartOf="parent"
    app:layout_constraintTop_toTopOf="@id/guideline_50" />

  <Button
    android:layout_width="0dp"
    android:layout_height="0dp"
    android:text="@string/twenty_percent"

    app:layout_constraintBottom_toBottomOf="parent"
    app:layout_constraintEnd_toEndOf="parent"
    app:layout_constraintStart_toStartOf="parent"
    app:layout_constraintTop_toTopOf="@id/guideline_80" />

</android.support.constraint.ConstraintLayout>
```

(from Containers/Sampler/app/src/main/res/layout/stacked_percent_cl.xml)

A `Guideline` has an orientation, set via `android:orientation`. Both of the `Guideline` widgets used here are `horizontal`. This means that they span the width of the `ConstraintLayout`, and something else has to indicate where they reside vertically within the `ConstraintLayout`.

In this case, that "something else" is the `app:layout_constraintGuide_percent` attribute. This indicates how far down from the start of the `ConstraintLayout` these `horizontal` `Guideline` widgets belong, in terms of a fraction of the overall height of

the `ConstraintLayout`. In this case, they appear 50% (`.50`) and 80% (`.80`) from the start.

Our three `Button` widgets do not specify their own heights — they use `0dp` for `android:layout_height`. Nor do they express their heights in terms of weights, the way the `LinearLayout` equivalent does. Instead, they use the same anchoring rules that are used all the time... except now, they can anchor to those two `Guideline` widgets in addition to each other and the `ConstraintLayout`.

So, our top `Button` has its top edge aligned with the top edge of the `ConstraintLayout` (`app:layout_constraintTop_toTopOf="parent"`). But it also has its bottom anchored to the top of the `.50 Guideline` (`app:layout_constraintBottom_toTopOf="@id/guideline_50"`). Combined with the `0dp` height, this stretches the `Button` between the top and the middle of the `ConstraintLayout`.

The middle `Button` anchors itself between the two `Guideline` widgets, using `app:layout_constraintBottom_toTopOf="@id/guideline_80"` and `app:layout_constraintTop_toTopOf="@id/guideline_50"`. It too stretches to fill that gap, and so it will take up 30% of the space (between the `.50` and the `.80` `Guideline` widgets).

Similarly, the bottom `Button` ties itself to the bottom of the `ConstraintLayout` (`app:layout_constraintBottom_toBottomOf="parent"`) as well as to the `.80` `Guideline` (`app:layout_constraintTop_toTopOf="@id/guideline_80"`).

To add a guideline through the graphical layout editor, use the toolbar button that looks like a vertical dotted line between two small solid horizontal lines. Clicking that opens up a drop-down to choose a vertical or a horizontal guideline:

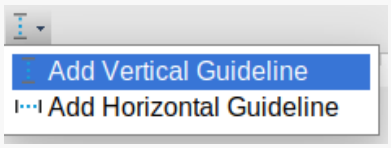

Figure 193: Guideline Toolbar Button, With Drop-Down

Choosing one of the guideline options drops a guideline in the desired orientation into the blueprint view, which you can then drag to the desired location.

Converting Existing Layouts

After spending some time with `ConstraintLayout`, you might decide that you want to try to standardize on it, converting existing layouts based on other containers to use `ConstraintLayout`.

Android Studio can help with this. In the design tab of a layout, if you right-click over an existing container in the component tree, you will have a "Convert ... to ConstraintLayout" context menu option. The "..." will be replaced by the container class that you clicked on (e.g., `LinearLayout`).

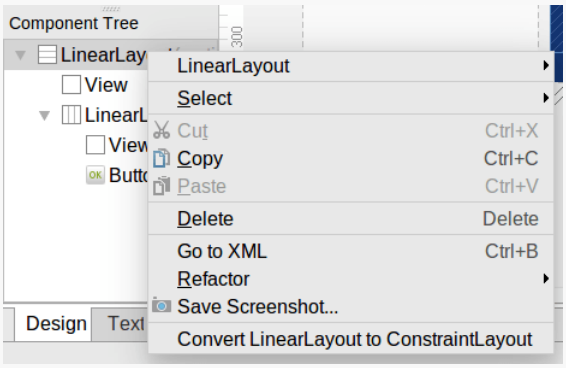

Figure 194: Convert to ConstraintLayout Context Menu

Choosing that menu option brings up a dialog for configuring the conversion:

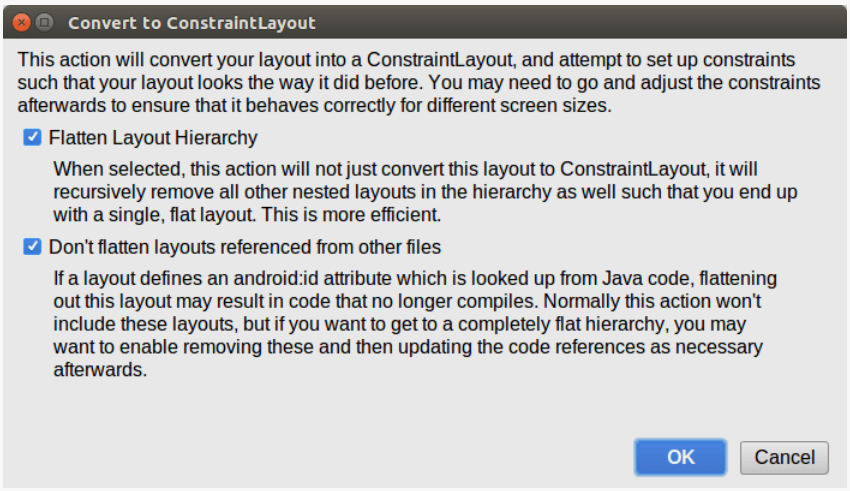

Figure 195: Convert to ConstraintLayout Dialog

The default behavior is to not only change the container that you clicked on, but all containers inside of it, to try to put everything into a single `ConstraintLayout`. However, if you have Java code that refers to some container that this conversion process would otherwise remove — for example, you are calling `findViewById()` on a widget ID that your Java code references — that container is left alone. Unchecking the second checkbox results in a more aggressive conversion, but it will leave you with broken Java code until you change whatever logic you have there to deal with the revised layout.

For simple layouts, the conversion process works fairly well. For complex layouts, the conversion process is more likely to give you invalid results, requiring manual tinkering, reversion to the original layout, or rewriting the layout from scratch.

For example, converting the `LinearLayout` edition of the complex form results in a layout that does not resemble the original:

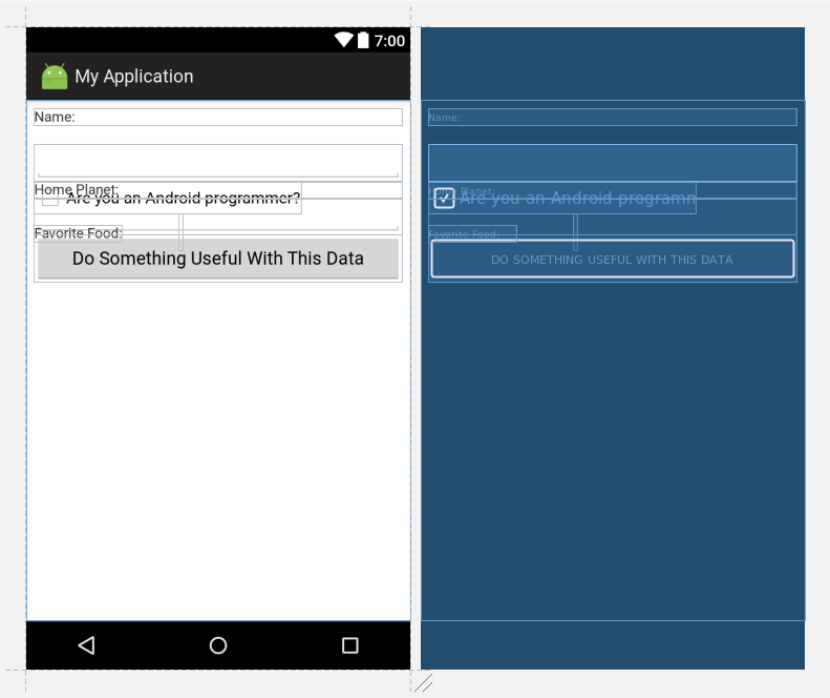

Figure 196: Complex LinearLayout Form, After Conversion

Attempting to convert the `TableLayout` edition of that same form results in a layout that will not compile properly.

Even seemingly simple layouts, such as the `RelativeLayout` overlap layout, fail to convert correctly:

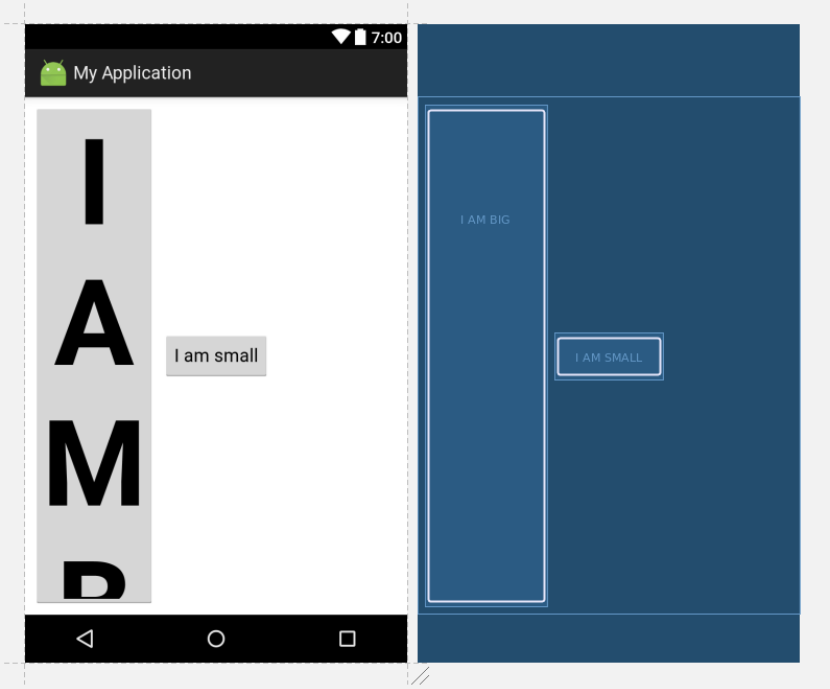

Figure 197: Not-So-Complex RelativeLayout Form, After Conversion

So, you are welcome to try it out and see if it works, but do not be surprised if it does not.

Visit the Trails!

There are more things that you can accomplish with a `ConstraintLayout` beyond what is presented here. There is a chapter on advanced `ConstraintLayout` techniques that get into more complex scenarios.

If you are interested in other containers from libraries, the book has a chapter on `GridLayout`.

The Action Bar

The action bar — that bar that runs across the top of your activity — is the backbone of your UI. Here, you can provide actions for the user to perform related to the current activity (e.g., "edit the contact that you are viewing") or related to the application as a whole (e.g., "here is the documentation"). Sometimes, these actions will appear as toolbar buttons or other widgets in the action bar. Sometimes, these actions will appear in the "overflow", which amounts to a menu.

This chapter introduces the concept of the action bar and how to add actions to it.

Bar Hopping

Android has had many patterns for various "bars" as part of its UI. So, to help explain what an action bar is, it helps if we review the history and role of Android's various bars.

Android 1.x/2.x

In the beginning, there was the status bar and the title bar.

The status bar was a thin strip across the top of the screen, used for things like the clock, signal strength, battery charge, and notification icons (for events like new unread email messages). This bar is technically part of the OS, not your app's UI.

The title bar was a thin gray strip beneath the status bar that, by default, would hold the name of your application, much like the title bar of a browser might show the name of a Web site.

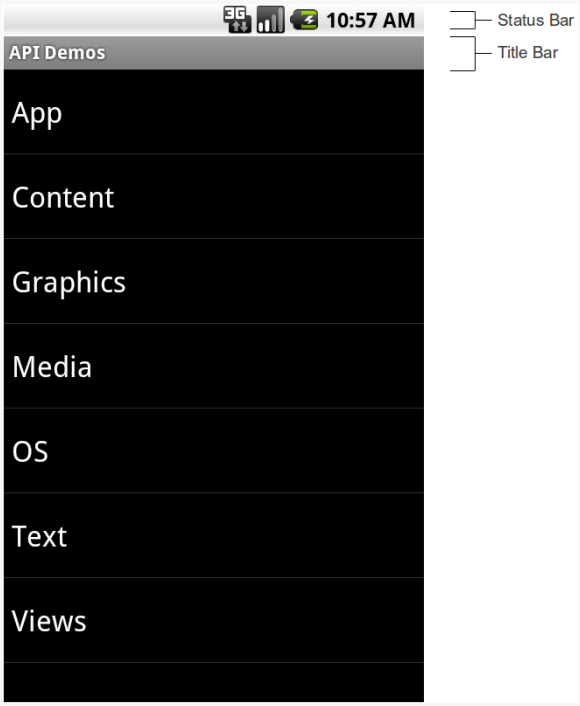

Figure 198: Status Bar and Title Bar

Android 3.0-4.1, Tablets

When official support for tablets arrived with Android 3.0 in February 2011, the story changed.

The status bar was replaced by the system bar, appearing at the bottom of the screen. This had all of the contents of the old status bar, but also had the soft keys for BACK, HOME, etc. Android 1.x and 2.x required that devices have off-screen affordances for those operations; now, device manufacturers could skip those and have the system bar offer them.

The action bar, by default, appears at the top of your activity, replacing the old title bar. You can define what goes in the action bar (icon, title, toolbar buttons, etc.).

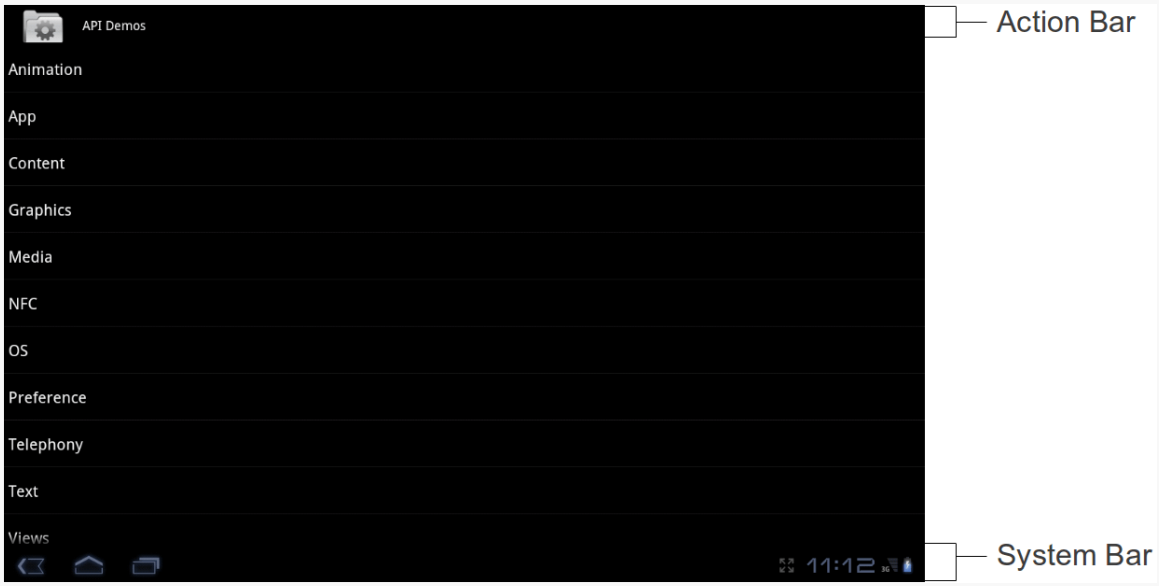

Figure 199: Action Bar and System Bar

The icon on the far left of the action bar also serves as a toolbar button, if you wish. A common pattern for using this is to take the user back to the "main" or "home" activity of your application.

Sometimes, the far right side of the action bar will contain a "..." affordance. This is known as the "action overflow" or "overflow menu":

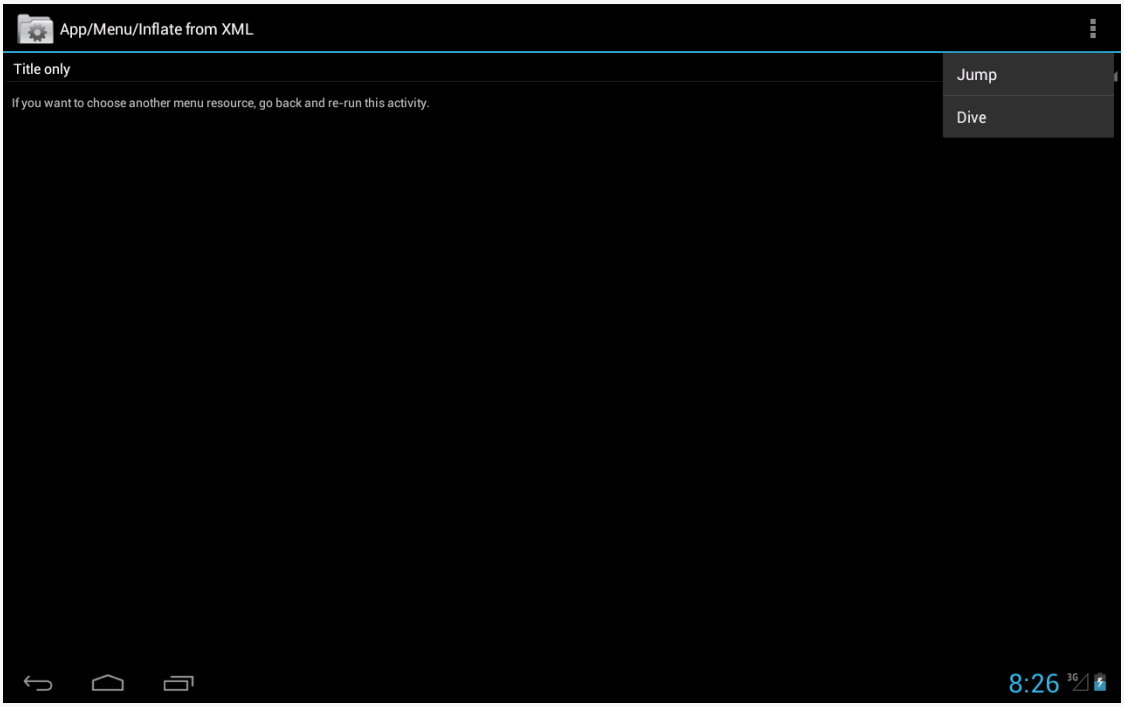

Figure 200: Action Bar with Open Overflow Menu

Tapping it will give the user access to actions that might have been toolbar buttons on a larger screen, but there was insufficient room. Also, low-priority actions may be tucked into the overflow, rather than clutter up the screen with too many toolbar buttons.

Android 4.0-4.4, Phones

Phone-sized devices were not supported by Android 3.x. They jumped from Android 2.3 to 4.0, and along the way adopted some of the Android 3.x UI features:

- Phone apps could have an action bar, like their tablet counterparts
- Device manufacturers could skip the BACK, HOME, etc. buttons and let a partial system bar handle those
- The status bar remained intact from the Android 2.x approach

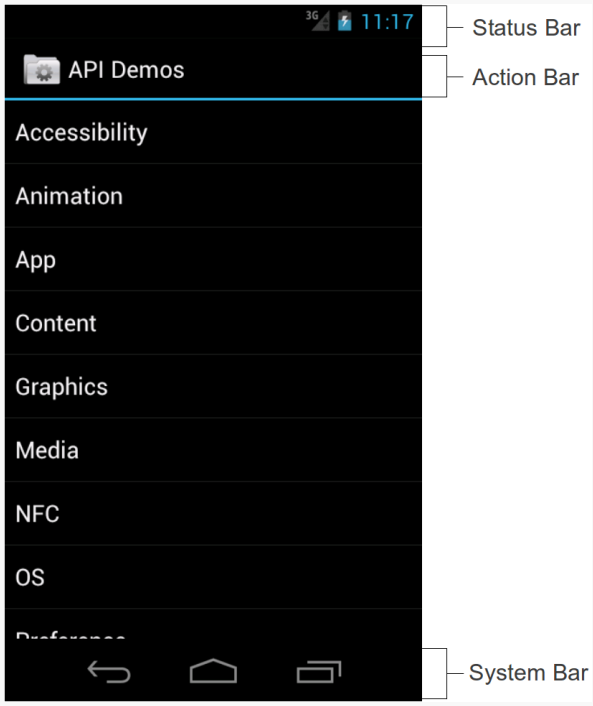

Figure 201: Status Bar, Action Bar, and System Bar

Android 4.2-4.4, Tablets

The Nexus 7, introduced in the summer of 2012, was a 7" tablet that did not follow the tablet UI structure that all other standard Android tablets used. Instead, it looked a bit like a really large phone, having a top status bar along with a bottom system bar solely for the navigation buttons (BACK, HOME, etc.). Apps, as before, could have an action bar as well.

Initially, it was thought that the Nexus 7 was going to be distinctive in that regard. Instead, with Android 4.2, Google switched all tablets to this model, restoring the status bar and relegating the system bar purely for navigation buttons.

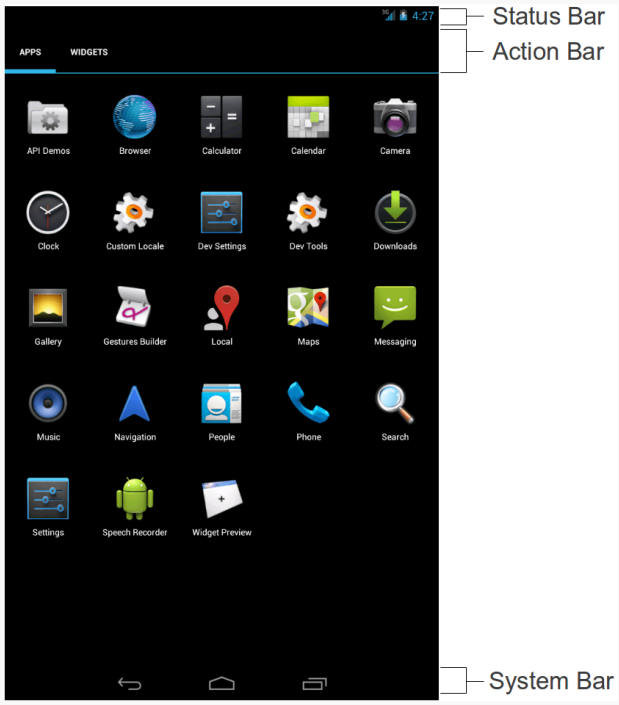

Figure 202: Status Bar, Action Bar, and System Bar, on Nexus 7 Emulator

Android 5.0+

Functionally, the action bar is much the same in Android 5.0 as it was in previous releases. However, aesthetically, it has dropped the icon and made other minor stylistic adjustments.

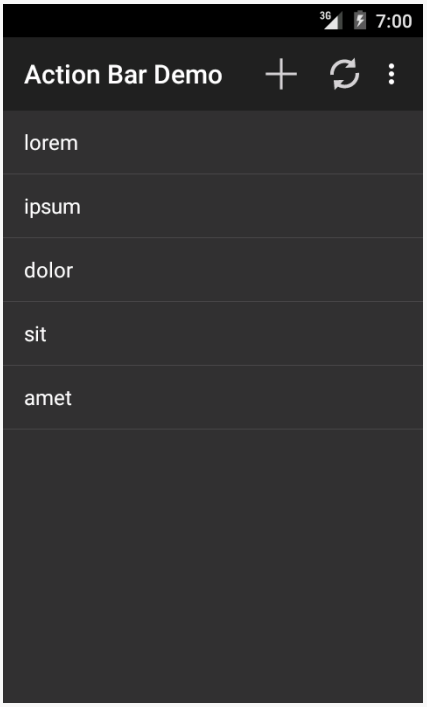

Figure 203: Action Bar on Android 5.0 Emulator

Yet Another History Lesson

Back in the dawn of Android time, referred to by some as "the year 2007", we had options menus. These would rise up from the bottom of the screen based on the user pressing a MENU key:

Figure 204: Legacy Options Menu

This is why you will see references to "options menu" scattered throughout the Android SDK.

The action bar pattern was first espoused by Google at the 2010 Google I|O conference. However, at the time, there was no actual implementation of this, except in scattered apps, and definitely not in the Android SDK.

Android 3.0 — a.k.a., API Level 11 — added the action bar to the SDK, and apps targeting that API level will get an action bar when running on such devices.

Your Action Bar Options

There are several implementations of the action bar floating about. You will probably be using the one that is part of Android itself, starting with API Level 11. However, there are a couple of backports of the action bar if you need them.

Pure Native

As mentioned above, devices running Android 3.0 and higher have support for the action bar as part of their firmware, and that support is exposed through the Android SDK. For example, there is an `ActionBar` class, and you can get an instance of it for your activity's action bar via `getActionBar()`.

However, this only works on devices running Android 3.0 and higher. If you try calling `getActionBar()` on an older device, you will crash with a `VerifyError` runtime exception. `VerifyError` is Android's way of telling you "while you compiled fine, something your compiled code refers to does not exist".

If your `minSdkVersion` is 11 or higher, you will be able to use the native action bar, and that approach will be used in most of this book.

Backports

If your `minSdkVersion` is lower than 11, you have two major choices:

1. Use the "menu" APIs in Android, which will add stuff to the action bar on newer devices, but will result in the classic "options menu" on older devices.
2. Use the `appcompat-v7` backport of the action bar, published by Google in the Android Support package in August 2013.

This chapter assumes that your `minSdkVersion` is set to 11 or higher and you will use the native action bar. A separate chapter in the trails cover the use of `appcompat-v7`.

Note that the `appcompat-v7` library not only backports the action bar, but also attempts to backport part of Google's Material Design styling. Normally, Material Design only comes from Android 5.0 and the use of `Theme.Material`. The `appcompat-v7` chapter will cover the library's effects both to the action bar and to other aspects of your app's UI.

A Quick Note About Toasts

In the sample app that follows, we use a `Toast` to let the user know some work has been completed.

A `Toast` is a transient message, meaning that it displays and disappears on its own without user interaction. Moreover, it does not take focus away from the currently-

active `Activity`, so if the user is busy writing the next Great Programming Guide, they will not have keystrokes be "eaten" by the message.

Since a `Toast` is transient, you have no way of knowing if the user even notices it. You get no acknowledgment from them, nor does the message stick around for a long time to pester the user. Hence, the `Toast` is mostly for advisory messages, such as indicating a long-running background task is completed, the battery has dropped to a low-but-not-too-low level, etc.

Making a `Toast` is fairly easy. The `Toast` class offers a static `makeText()` method that accepts a String (or string resource ID) and returns a `Toast` instance. The `makeText()` method also needs the `Activity` (or other `Context`) plus a duration. The duration is expressed in the form of the `LENGTH_SHORT` or `LENGTH_LONG` constants to indicate, on a relative basis, how long the message should remain visible. Once your `Toast` is configured, call its `show()` method, and the message will be displayed.

Setting the Target

If you want proper action bar support, you will want to target API Level 14 or higher at runtime. That involves setting the `targetSdkVersion` property in your `build.gradle` file (for Android Studio users) or setting the `android:targetSdkVersion` attribute of the `<uses-sdk>` element of your manifest (for legacy pre-Gradle projects).

We see this in the manifest of the [ActionBar/ActionBarDemoNative] sample project:

```
<?xml version="1.0" encoding="utf-8"?>
<manifest xmlns:android="http://schemas.android.com/apk/res/android"
  package="com.commonsware.android.inflation"
  android:versionCode="1"
  android:versionName="1.0">

  <supports-screens
    android:anyDensity="true"
    android:largeScreens="true"
    android:normalScreens="true"
    android:smallScreens="true"/>

  <uses-sdk
    android:minSdkVersion="10"
    android:targetSdkVersion="19"/>

  <application
```

```
    android:allowBackup="false"
    android:icon="@drawable/ic_launcher"
    android:label="@string/app_name">
    <activity
      android:name=".ActionBarDemoActivity"
      android:label="@string/app_name">
      <intent-filter>
        <action android:name="android.intent.action.MAIN"/>

        <category android:name="android.intent.category.LAUNCHER"/>
      </intent-filter>
    </activity>
  </application>

</manifest>
```

(from ActionBar/ActionBarDemoNative/app/src/main/AndroidManifest.xml)

Specifically, we have `android:targetSdkVersion` set to 19. While 11 or higher will give you an action bar, 14 or higher will solve a particular UI quirk related to menu choices. Some Android 4.0+ devices, but not all, will show *two* ways of getting at overflow menu items if you have your `android:targetSdkVersion` set to a value between 11 and 13. You will have the "..." item in the action bar itself *and* a second one in the system bar, on devices that have one. Setting `android:targetSdkVersion` to 14 or higher resolves this.

Doing nothing else but the preceding steps would give us an action bar, but one with no toolbar icons or action overflow menu. While perhaps visually appealing, this is not terribly useful for the user, so we need to do some more work to give the user actions to perform from the action bar.

Note that this manifest has a `minSdkVersion` of 10. This means that the app can run on Android 2.3.3 devices. On those devices, though, the app will not have an action bar, as the action bar did not exist then, and this app is not using a backport like `appcompat-v7`. Instead, the app will have an old-style options menu on API Level 10 devices. There is nothing intrinsically wrong with this, though it does mean that your app will look different on API Level 10 devices.

Defining the Resource

The easiest way to get toolbar icons and action overflow items into the action bar is by way of a menu XML resource. This is called a "menu" resource for historical reasons, as these resources originally were used for things like the options menu.

You can add a `res/menu/` directory to your project and place in there menu XML resources, such as `res/menu/actions.xml` from `ActionBar/ActionBarDemoNative`:

```
<?xml version="1.0" encoding="utf-8"?>
<menu xmlns:android="http://schemas.android.com/apk/res/android">

  <item
    android:id="@+id/add"
    android:icon="@drawable/ic_action_new"
    android:showAsAction="always"
    android:title="@string/add"/>
  <item
    android:id="@+id/reset"
    android:icon="@drawable/ic_action_refresh"
    android:showAsAction="always|withText"
    android:title="@string/reset"/>
  <item
    android:id="@+id/about"
    android:icon="@drawable/ic_action_about"
    android:showAsAction="never"
    android:title="@string/about">
  </item>

</menu>
```

(from ActionBar/ActionBarDemoNative/app/src/main/res/menu/actions.xml)

There are four things you will want to configure on every menu item (`<item>` element in the XML):

1. The ID of the item (via the `android:id` attribute in XML). This will create another `R.id` value, associated with this menu item, much like the `R.id` values for our widgets in our layouts. We will use this ID to determine when the user clicks on one of our toolbar buttons or action overflow items.
2. The title of the item (via the `android:title` attribute in XML). If this item winds up in the action overflow menu, or optionally as part of its toolbar button, this text will appear. Also, this title will appear as a "tooltip" on the action item in the action bar itself, if the user long-presses on the icon (something few users know to do). Typically, you will use a string resource reference (e.g., `@string/add`), to better support internationalization.
3. The icon for the item (via the `android:icon` attribute in XML). If your item will appear as a toolbar button, this icon is used with that button.
4. Flags indicating how this item should be portrayed in the action bar (via the `android:showAsAction` attribute in XML). You will choose to have it be

`always` a toolbar button, only be a toolbar button `ifRoom`, or have it `never` be a toolbar button. You can also elect to append `|withText` to either `always` or `ifRoom`, to indicate that you want the toolbar button to be both the icon and the title, not just the icon. Note that `always` is not *guaranteed* to be a toolbar button — if you ask for 100 `always` items, you will not have room for all of them. However, `always` items get priority for space in the action bar over `ifRoom` items.

A Quick Note About Android Studio

Android Studio 2.2 introduced a new menu editor, modeled after the graphical layout editor. When you open a menu resource, you get two sub-tabs: a Text one with the XML, and a Design one to preview the menu and, in theory, edit it:

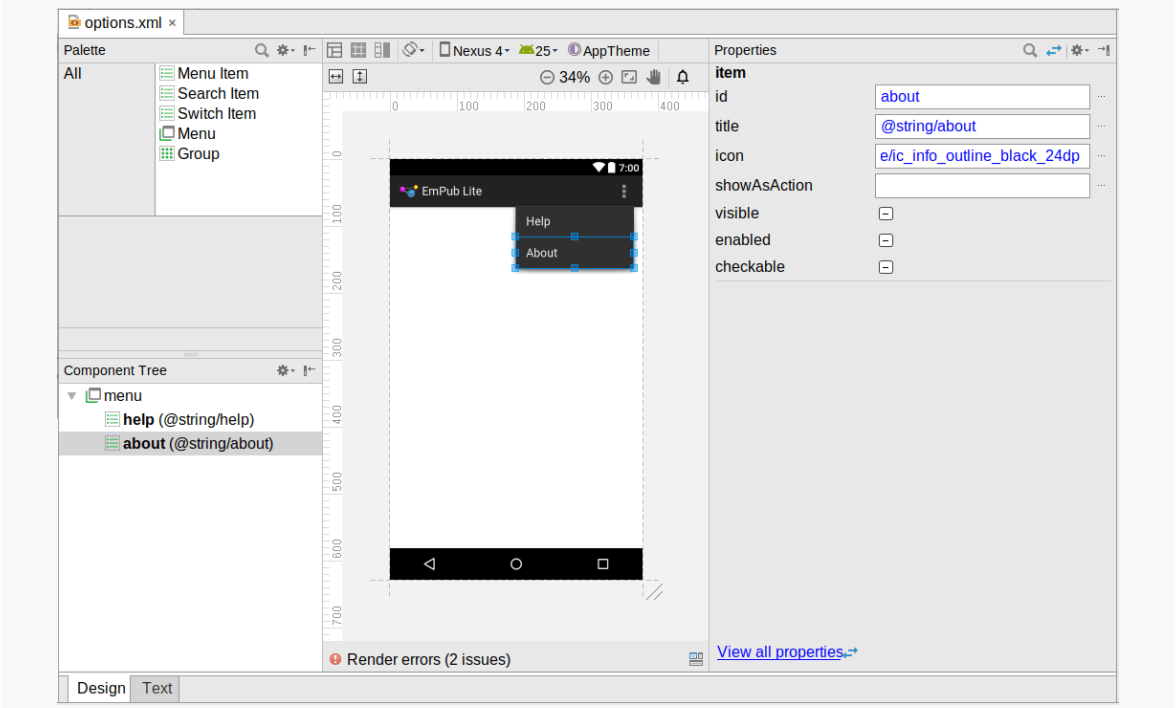

Figure 205: Android Studio Graphical Menu Editor

Unfortunately, the Design sub-tab suffers from this bug, making it annoying to use. For the time being, you are better off working with the XML directly.

Applying the Resource

From your activity, you teach Android about these action bar items by overriding an `onCreateOptionsMenu()` method, such as this one from the `ActionBarDemoActivity` of the `ActionBar/ActionBarDemoNative` sample project:

```
@Override
public boolean onCreateOptionsMenu(Menu menu) {
  getMenuInflater().inflate(R.menu.actions, menu);

  return(super.onCreateOptionsMenu(menu));
}
```

(from ActionBar/ActionBarDemoNative/app/src/main/java/com/commonsware/android/inflation/ActionBarDemoActivity.java)

Here, we create a `MenuInflater` and tell it to inflate our menu XML resource (`R.menu.actions`) and pour them into the supplied `Menu` object. We then chain to the superclass, returning its result.

Responding to Events

To find out when the user taps on one of these things, you will need to override `onOptionsItemSelected()`, such as the `ActionBarDemoActivity` implementation shown below:

```
@Override
public boolean onOptionsItemSelected(MenuItem item) {
  switch(item.getItemId()) {
    case R.id.add:
      addWord();

      return(true);

    case R.id.reset:
      initAdapter();

      return(true);

    case R.id.about:
      Toast.makeText(this, R.string.about_toast, Toast.LENGTH_LONG)
           .show();

      return(true);
  }
```

```
    return(super.onOptionsItemSelected(item));
  }
```

(from ActionBar/ActionBarDemoNative/app/src/main/java/com/commonsware/android/inflation/ActionBarDemoActivity.java)

You will be passed a `MenuItem`. You can call `getItemId()` on it and compare that value to the ones from your menu XML resource (`R.id.add` and `R.id.reset`). If you handle the event, return `true`; otherwise, return the value of chaining to the superclass' implementation of the method.

If you wish to respond to taps on your application icon, on the left of the action bar, compare `getItemId()` to `android.R.id.home`, as that will be the `MenuItem` used for that particular toolbar button. Note that if you have your `android:targetSdkVersion` set to `14` or higher, you will also need to call `setHomeButtonEnabled(true)` on the `ActionBar` (obtained via a call to `getActionBar()`) to enable this behavior. Note that this icon may not exist, particularly if you are using `Theme.Material` on Android 5.0+.

The Rest of the Sample Activity

So, what is it that we really are doing here in `ActionBarDemoActivity`?

In many respects, this is reminiscent of the `ListActivity` demos from an earlier chapter. We have an array of 25 Latin words, and we want to display these in a list.

However, in this case, we are only showing five words at the outset. An "add" action bar item will add additional words out of the main roster of 25 words, until the `ListView` holds all 25. A "reset" action bar item will return us to the original 5 words.

`ActionBarDemoActivity` is a `ListActivity`. However, rather than set up our `ArrayAdapter` directly in the `onCreate()` method as some of the other samples have done, we delegate that work to an `initAdapter()` method. Moreover, that `initAdapter()` method does its work a bit differently than what those other samples did:

```
  private void initAdapter() {
    words=new ArrayList<String>();

    for (int i=0;i<5;i++) {
      words.add(items[i]);
    }
```

```
    adapter=
        new ArrayAdapter<String>(this,
                                 android.R.layout.simple_list_item_1,
                                 words);

    setListAdapter(adapter);
  }
```

(from ActionBar/ActionBarDemoNative/app/src/main/java/com/commonsware/android/inflation/ActionBarDemoActivity.java)

Rather than create the `ArrayAdapter` straight out of the static `items` array, we create a fresh `ArrayList` and pour the 5 elements from `items` into it, then create the `ArrayAdapter` on the `ArrayList`. This may seem superfluous, but we will take advantage of this approach with our action bar items.

When the user clicks the "reset" item in the action bar, we call `initAdapter()` again, which gives our `ListActivity` a fresh set of 5 Latin words to display:

```
@Override
public boolean onOptionsItemSelected(MenuItem item) {
  switch(item.getItemId()) {
    case R.id.add:
      addWord();

      return(true);

    case R.id.reset:
      initAdapter();

      return(true);

    case R.id.about:
      Toast.makeText(this, R.string.about_toast, Toast.LENGTH_LONG)
           .show();

      return(true);
  }

  return(super.onOptionsItemSelected(item));
}
```

(from ActionBar/ActionBarDemoNative/app/src/main/java/com/commonsware/android/inflation/ActionBarDemoActivity.java)

When the user clicks the "add" item in the action bar, we call an `addWord()` private method, which adds the next word out of the `items` array and appends it to the `ListView`:

```
private void addWord() {
  if (adapter.getCount()<items.length) {
    adapter.add(items[adapter.getCount()]);
  }
}
```

(from ActionBar/ActionBarDemoNative/app/src/main/java/com/commonsware/android/inflation/ActionBarDemoActivity.java)

The net result of all of this is that we have an activity with our customized action bar:

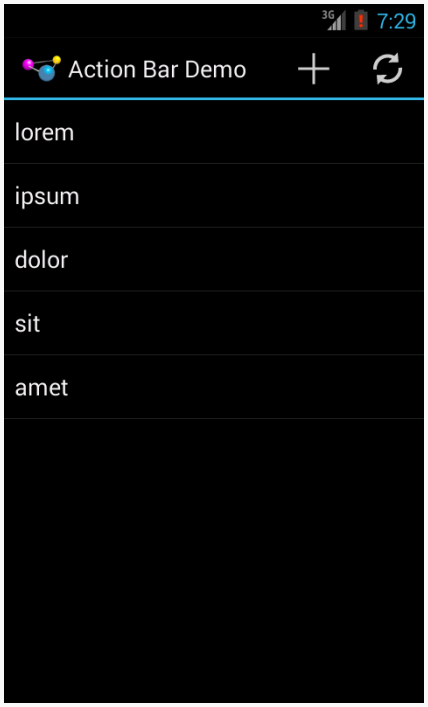

Figure 206: ActionBarDemo, As Initially Launched, on Android 4.3

Among our action bar items is an "about" one that will always be in the overflow menu. This will have three possible visual outcomes.

First, on devices without an off-screen MENU key, the overflow menu is represented by a "..." button, which displays the overflow menu when clicked:

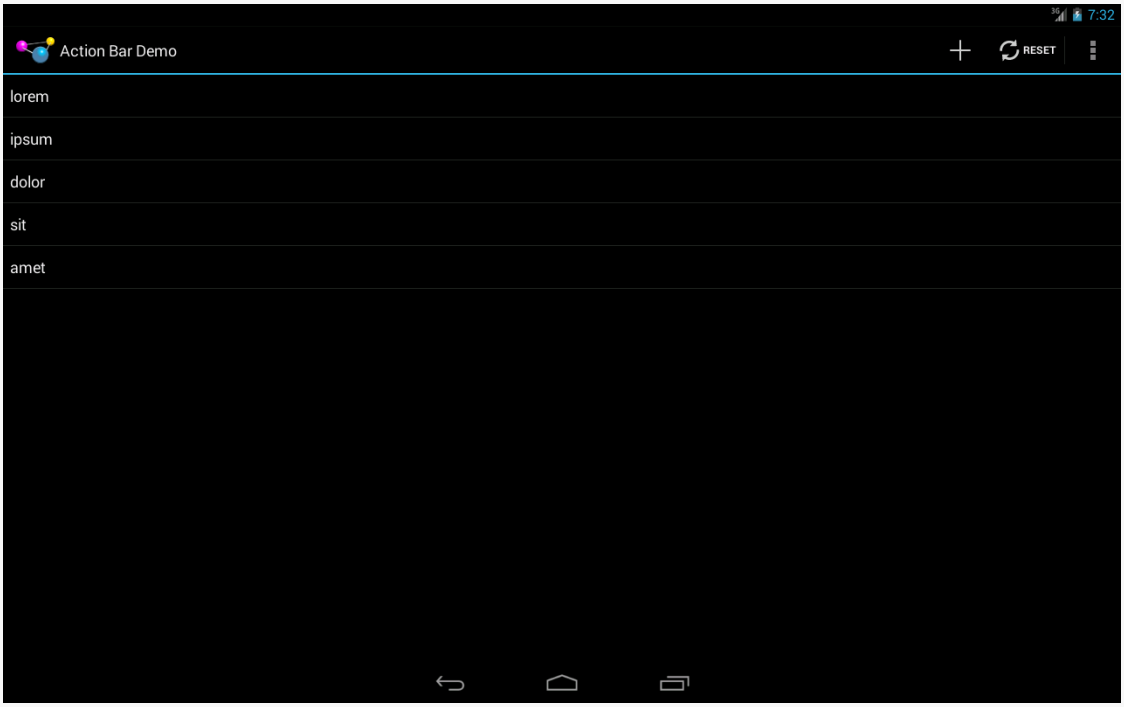

Figure 207: ActionBarDemo, on Android 4.3 Large Screen, with Overflow

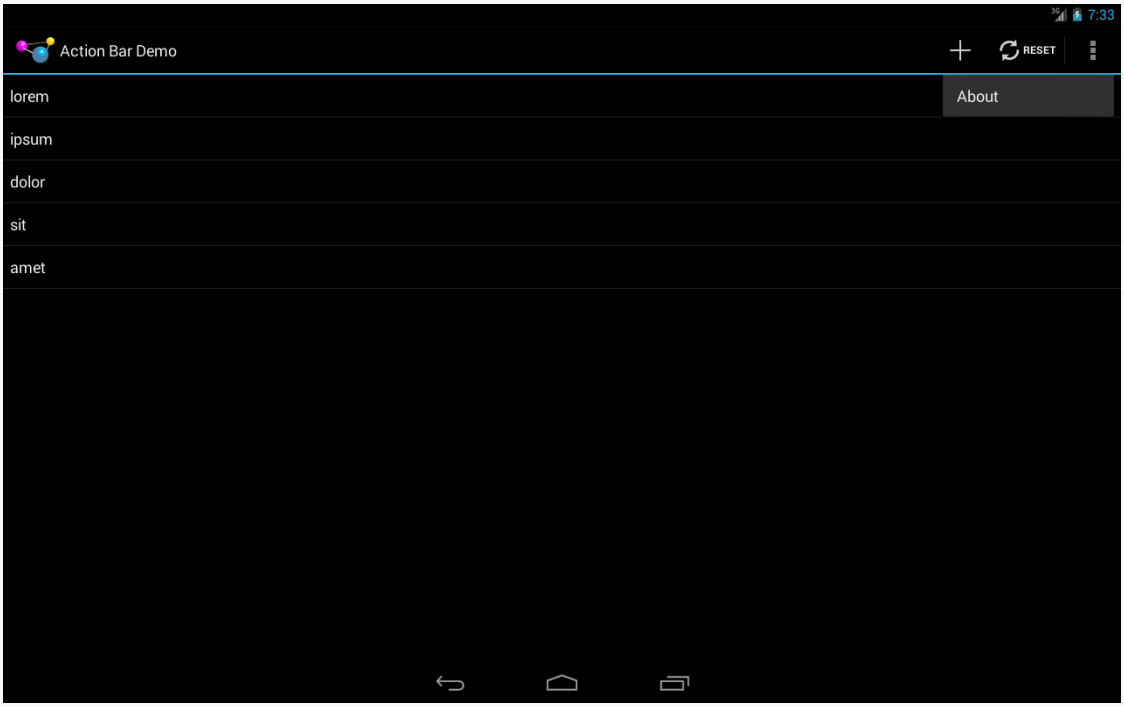

Figure 208: ActionBarDemo, on Android 4.3 Large Screen, with Overflow Open

On Android 4.x devices with an off-screen MENU key, pressing the MENU key will cause the overflow menu to rise up from the bottom of the screen:

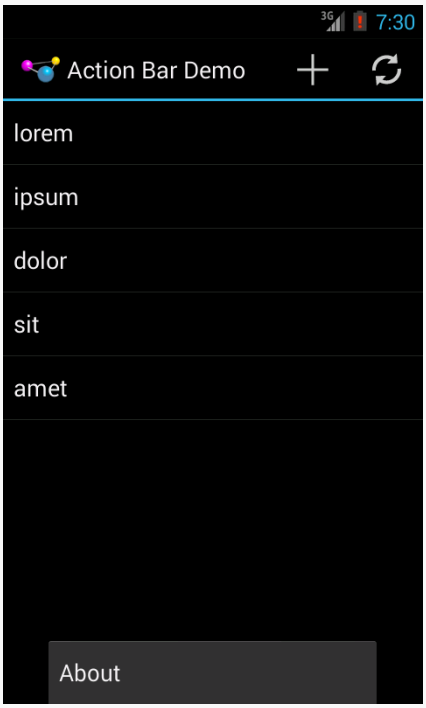

Figure 209: ActionBarDemo, on Android 4.3 Normal Screen, with Overflow

Android 4.4+ devices should always have the "..." button, as is described in the next section.

Android 2.3 devices that run this app will have no action bar:

Figure 210: ActionBarDemo, on Android 2.3.3 Normal Screen

However, pressing the MENU button will bring up the old-style options menu, where our action items appear:

Figure 211: ActionBarDemo, on Android 2.3.3 Normal Screen, Showing the Options Menu

MENU Key, We Hardly Knew Ye

To expand upon the history lessons from earlier in this chapter, all Android 1.x and 2.x devices had a MENU key, used to bring up the options menu. With Android 3.0 and the advent of the system/navigation bar, device manufacturers no longer needed keys for HOME, BACK, and MENU. And, the action bar incorporated a "..." affordance for accessing the overflow, for items that would have been in the options menu and were not promoted to be toolbar buttons in the action bar itself.

Confusion began when we started having devices that *had* a MENU key *and* Android 3.0+. A few Android 2.x devices were upgraded to Android 4.0, and hundreds of millions of Android devices, from manufacturers like Samsung and HTC, shipped with Android 4.x and a MENU key.

To accommodate this, the device would report whether it had a "permanent menu key", and the action bar would choose whether to show the "..." affordance based upon the existence of this key. Devices with a MENU key would not get the "...", but instead would use the MENU key to display the overflow.

This irritated many developers, for much the same reason as why the MENU key irritated those developers back in Android 1.x/2.x: the existence of a menu was not very discoverable. Many users would eventually realize that tapping the MENU key might uncover useful stuff, but not all users would make this connection. However, now developers could see an obvious alternative, in the form of the "..." affordance, and so they sought ways to trick the action bar into showing the "..." even on devices that had a MENU key.

And that was how the world worked... up until Android 4.4.

An unannounced change in Android 4.4 is that the "..." button should now *always* be shown in the action bar. The MENU key, if it exists, will still work, showing the overflow. Ideally, it shows the overflow as dropping down from the "...", though that is not required. And the Compatibility Definition Document for Android 4.4 more forcefully suggests that the MENU key is obsolete.

None of this should directly affect your code. However:

- When taking screenshots, bear in mind that they will vary between devices that have the "..." button and those that do not
- When writing documentation, or blog posts, or other instructional material, try to phrase references to the overflow that will work for both those users with a "..." button and those that do not

Action Bars, Live in Living Color!

On Android 4.0+, if you are using a `Holo` theme as a base, you may wish to adjust the colors used by your action bar.

On Android 5.0+, if you are using a `Material` theme as a base, you *will* want to adjust the colors used by your action bar. This is Google's vision for how branding should work, in lieu of having your icon be in the action bar.

The following sections outline some ways to affect the colors of your action bar.

Material Tint Effects

Android 5.0 and `Theme.Material` make action bar colors easy to set up, as part of an overall "tinting" approach.

The ActionBar/MaterialColor sample project is a clone of the ActionBarDemoNative sample shown earlier in this chapter, but one where:

- Our minSdkVersion is set to 21, so the app will only run on Android 5.0+
- We set up a custom theme, with specific tinting rules, that affect our action bar colors

Color Resources

The theme will need to refer to colors, and the cleanest way to do that is to set up color resources. Like all of our other resources, we give color resources a name and a color value, usually in #RRGGBB or #AARRGGBB format. Color resources are "value" resources, held by default in res/values/, with the convention of using a colors.xml file for the actual colors.

For example, here is the res/values/colors.xml file from the MaterialColor sample application:

```
<?xml version="1.0" encoding="utf-8"?>
<resources>
  <color name="primary">#3f51b5</color>
  <color name="primary_dark">#1a237e</color>
  <color name="accent">#ffee58</color>
</resources>
```

(from ActionBar/MaterialColor/app/src/main/res/values/colors.xml)

It defines three colors, primary, primary_dark, and accent, with different colors for each. In Android Studio, editing this file shows a tiny color swatch to help you visualize the colors:

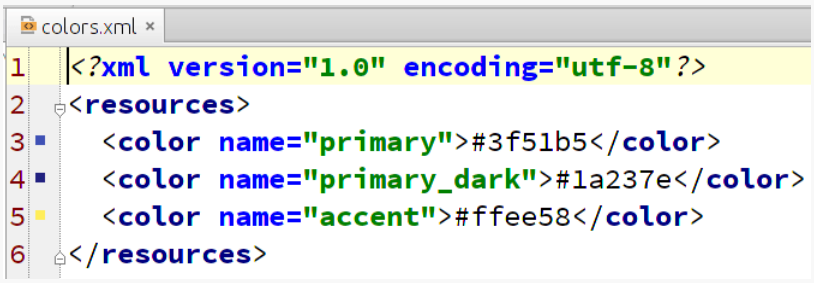

Figure 212: Color Resources in Android Studio

Tinting a Theme

Then, given that we have definitions of our colors, we can apply those colors to a custom theme, found in `res/values/styles.xml`:

```
<?xml version="1.0" encoding="utf-8"?>
<resources>
  <style name="AppTheme" parent="android:Theme.Material">
    <item name="android:colorPrimary">@color/primary</item>
    <item name="android:colorPrimaryDark">@color/primary_dark</item>
    <item name="android:colorAccent">@color/accent</item>
  </style>
</resources>
```

(from ActionBar/MaterialColor/app/src/main/res/values/styles.xml)

Here, our `AppTheme` is inheriting from `Theme.Material` and is overriding three tints: `colorPrimary`, `colorPrimaryDark`, and `colorAccent`, referring to our three color resources in turn.

Note that we could have inherited from `Theme.Material.Light` had we wanted a light "content area" (where our widgets go), or even `Theme.Material.Light.DarkActionBar` for a light content area and a dark action bar (before we start tailoring the action bar colors).

Applying the Theme

The application's manifest declares that we will use `AppTheme` as the default theme for our `<application>`, so all activities will use that theme unless overridden at the activity level:

```
<?xml version="1.0" encoding="utf-8"?>
<manifest xmlns:android="http://schemas.android.com/apk/res/android"
  package="com.commonsware.android.abmatcolor"
  android:versionCode="1"
  android:versionName="1.0">

  <supports-screens
    android:anyDensity="true"
    android:largeScreens="true"
    android:normalScreens="true"
    android:smallScreens="true"/>

  <uses-sdk
```

```
    android:minSdkVersion="21"
    android:targetSdkVersion="21" />

  <application
    android:allowBackup="false"
    android:icon="@drawable/ic_launcher"
    android:label="@string/app_name"
    android:theme="@style/AppTheme">
    <activity
      android:name="ActionBarDemoActivity"
      android:label="@string/app_name">
      <intent-filter>
        <action android:name="android.intent.action.MAIN" />

        <category android:name="android.intent.category.LAUNCHER" />
      </intent-filter>
    </activity>
  </application>

</manifest>
```

(from ActionBar/MaterialColor/app/src/main/AndroidManifest.xml)

Also note that here is where we specify that `minSdkVersion` is 21. A new Android Studio project would do that in `build.gradle`.

The Results

Everything else about the app is the same as the `ActionBarDemoNative` sample, including our activity and the `ListView` that we are populating.

However, when we run this edition on an Android 5.0+ device or emulator, our action bar takes on the requested colors, specifically the `colorPrimary` value for the background color of the action bar:

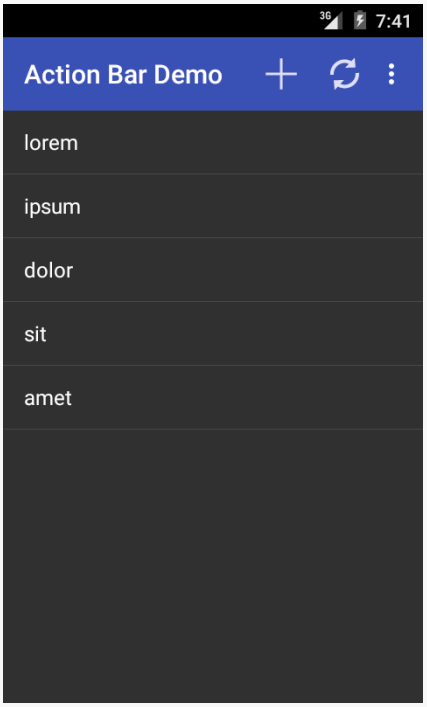

Figure 213: MaterialColor on Android 5.0 Emulator

The custom theme also affects the colors of certain widgets, as will be covered later in the book.

Restoring the Icon (Sort Of)

While the Material Design philosophy skips the application icon that we used to have in the action bar, there is a way to add it back for a `Theme.Material` application, though it requires a little bit of work, as seen in the `ActionBar/MaterialLogo` sample project.

The key thing that you need to do is to call `setDisplayShowHomeEnabled(true)` on your `ActionBar` object, which you get by calling `getActionBar()` in your `Activity`:

```
@Override
public void onCreate(Bundle state) {
  super.onCreate(state);

  getActionBar().setDisplayShowHomeEnabled(true);

  initAdapter();
}
```

(from ActionBar/MaterialLogo/app/src/main/java/com/commonsware/android/abmatlogo/ActionBarDemoActivity.java)

This will use whatever icon is set for the `android:icon` attribute in your manifest as the "home" icon in your action bar:

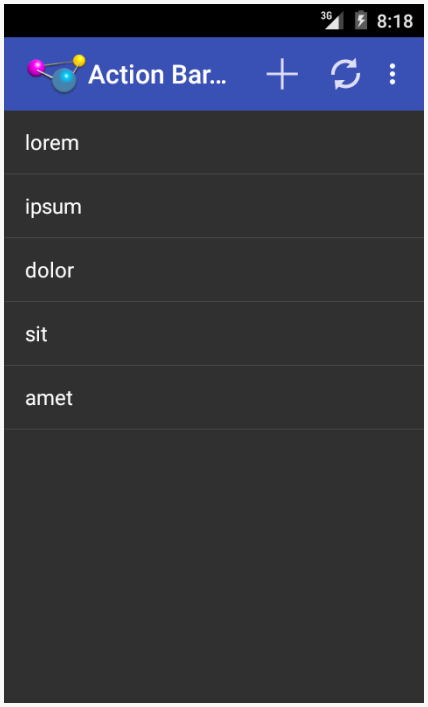

Figure 214: MaterialLogo on Android 5.0 Emulator

If you would rather use a different icon, such as one that is scaled to fit the action bar a bit better, you can call `setIcon()` on your `ActionBar`, supplying the ID of a drawable resource (e.g., `R.drawable.action_bar_icon`) that should be used instead of the drawable specified in the `android:icon` attribute of your `<activity>` or `<application>` in the manifest.

Action Bar Style Generator

For `Theme.Holo` and kin, the tinting rules from `Theme.Material` will not apply. Instead, you will need to do a fair bit of tinkering to get the color scheme set up the way you want.

Or, you can use Jeff Gilfelt's Action Bar Style Generator.

This is a Web site that allows you to design an action bar color scheme, where the site will then generate for you everything that you need to implement that color scheme.

Note that Mr. Gilfelt has marked this site as deprecated, with an eye towards people using `Theme.Material` or the `appcompat-v7` edition of the action bar. The site works, but in all likelihood it will be discontinued at some future date.

Also note that the site works best with Google's Chrome or Chromium browsers, though in testing, a recent edition of Firefox worked as well. As the site indicates, "your mileage may vary with other browsers".

Designing the Scheme

The site is dominated by a form for designing the color scheme and a preview area to show what the design will look like:

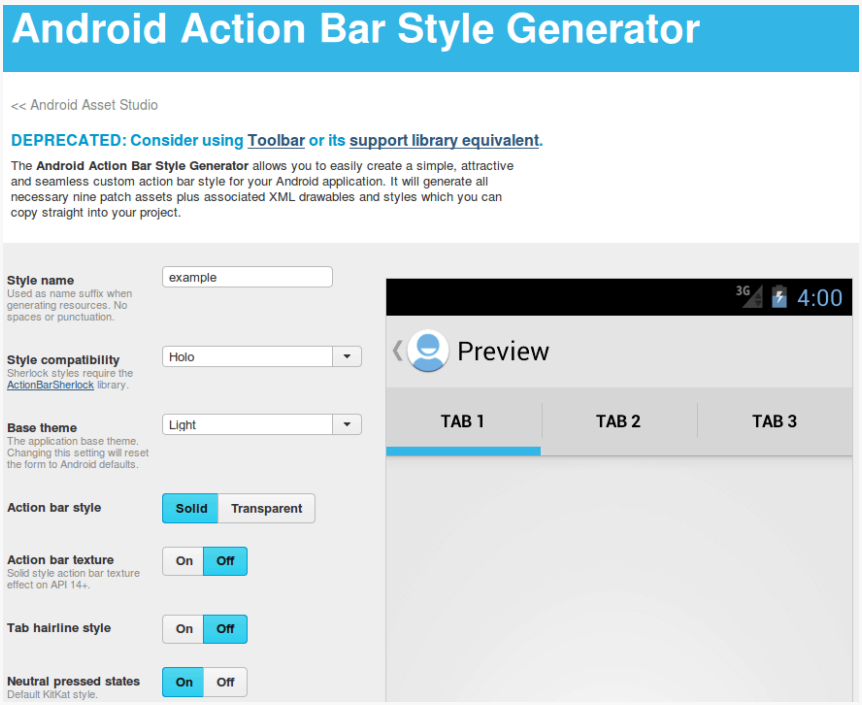

Figure 215: Action Bar Style Generator, As Originally Launched

In the "Style name" field, you can fill in the name you want to give your custom theme. Whatever you fill in will be converted into all lowercase with a leading

capital letter, all following `Theme.`. So, for example, filling in `AppTheme` will result in a style resource named `Theme.Apptheme`.

For "Style compatibility", choose "Holo". For "Base theme", choose the base style you want:

- Light
- Dark
- Light with dark action bar

The next four options ("Action bar style", "Action bar texture", "Tab hairline style", "Neutral pressed states") are for advanced features and can be left at their defaults.

Scrolling further down the page, you will come to seven color pickers, allowing you to tailor the colors to be used in your action bar implementation. Each picker, when opened, allows you to choose a color based on a fixed palette, then refined using a gradient selector. Or, if you know specific colors (e.g., a graphic designer gave them to you), you can fill the color into the supplied field:

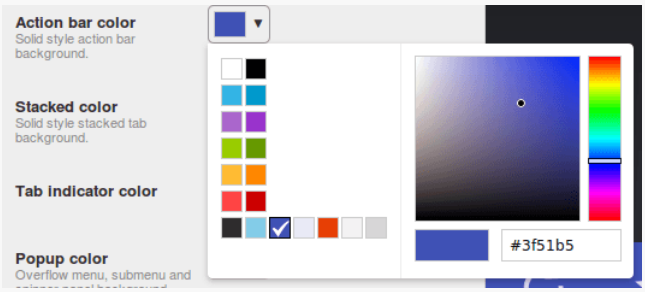

Figure 216: Action Bar Style Generator, Showing "Action bar color" Picker

As you change the colors, you will see what they impact on the preview.

At the bottom of the page is the "Output resources" frame:

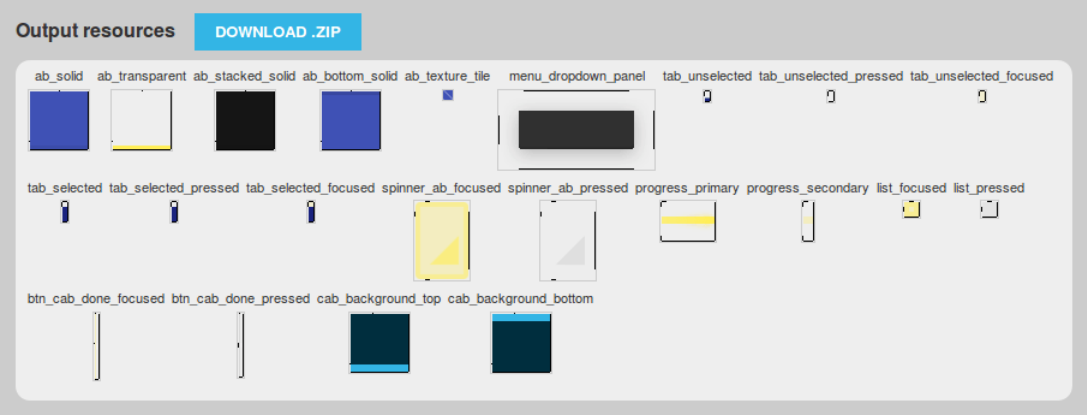

Figure 217: Action Bar Style Generator, Showing "Output resources" Frame

Here, you can click on the "DOWNLOAD .ZIP" button to download a ZIP archive containing your custom theme and all the associated resources required to implement it.

Implementing the Scheme

UnZIP the contents of that ZIP archive into your project's `res/` directory (e.g., in a traditional Android Studio project, unZIP into `src/main/res/` in your `app` module). It will add a bunch of files, notably including a file in `res/values/` whose name is based upon the name you filled into the Web form for the theme name (e.g., `styles_apptheme.xml`).

If you look at that file, you will see that it defines a custom theme for you, named `Theme.` plus whatever you provided to that form (converted into a leading capital letter and the rest lowercase). That file will be rather lengthy, as it designates specific styles to use for various facets of the action bar (e.g., `android:actionBarStyle`).

Here is the theme's primary `<style>` resource element, defining the theme itself:

```
<style name="Theme.Apptheme" parent="@android:style/Theme.Holo">
    <item name="android:actionBarItemBackground">@drawable/selectable_background_apptheme</item>
    <item name="android:popupMenuStyle">@style/PopupMenu.Apptheme</item>
    <item name="android:dropDownListViewStyle">@style/DropDownListView.Apptheme</item>
    <item name="android:actionBarTabStyle">@style/ActionBarTabStyle.Apptheme</item>
    <item name="android:actionDropDownStyle">@style/DropDownNav.Apptheme</item>
    <item name="android:actionBarStyle">@style/ActionBar.Solid.Apptheme</item>
    <item name="android:actionModeBackground">@drawable/cab_background_top_apptheme</item>
    <item name="android:actionModeSplitBackground">@drawable/cab_background_bottom_apptheme</item>
    <item name="android:actionModeCloseButtonStyle">@style/ActionButton.CloseMode.Apptheme</item>
```

```
  </style>
```

(from ActionBar/HoloColor/app/src/main/res/values/styles_apptheme.xml)

To use this theme, just add an `android:theme` attribute to your `<application>` (or perhaps individual `<activity>` elements) in your manifest:

```
<application
  android:allowBackup="false"
  android:icon="@drawable/ic_launcher"
  android:label="@string/app_name"
  android:theme="@style/Theme.Apptheme">
  <activity
    android:name="ActionBarDemoActivity"
    android:label="@string/app_name">
    <intent-filter>
      <action android:name="android.intent.action.MAIN"/>

      <category android:name="android.intent.category.LAUNCHER"/>
    </intent-filter>
  </activity>
</application>
```

(from ActionBar/HoloColor/app/src/main/AndroidManifest.xml)

The resulting app will have a color scheme mirroring what you defined on the form:

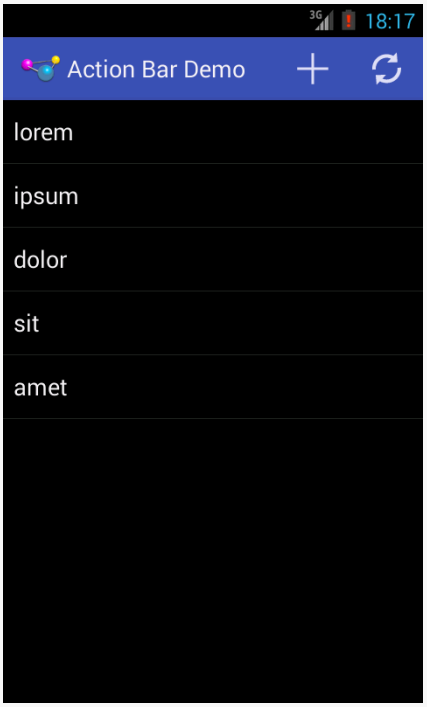

Figure 218: Results of the Action Bar Style Generator

This screenshot, and the code snippets, comes from the `ActionBar/HoloColor` sample project, which is the same as the base action bar sample app from this chapter with the custom theme applied.

Visit the Trails!

In addition to this chapter, you can learn more about advanced action bar techniques and learn about action modes, which temporarily replace the action bar with new items for use with contextual operations.

Vector Drawables

Android 5.0 added native support for a `VectorDrawable`, which uses the SVG path specification to represent vector art. However, unless your `minSdkVersion` was 21 or higher, vector drawable resources were not that useful, as there was no good way to support the same artwork on older devices. You could somehow arrange to have PNGs for the same artwork, but then, why bother with the vector artwork in the first place?

Nowadays, vector drawable resources are more practical. Not only do more devices run Android 5.0+, but we have better tool support. Android Studio offers a Vector Asset wizard that helps you add vector drawable resources to your project, and the build system can automatically generate PNG files at various densities to be used on older devices.

As a result, vector drawables have been gaining in popularity, particularly for action bar icons.

Getting the Artwork

You have two major sources of vector drawable artwork: XML files already in the vector drawable XML format, or SVG files that you wish to convert to vector drawable XML format. Since writing the vector drawable XML by hand will be difficult at best, most vector drawable XML will start from an SVG file. Whether you do the conversion, or whether somebody else did the conversion for you, is the major difference.

For SVG that you wish to try to convert to vector drawable XML, the simpler the SVG is, the more likely it is that you will have success. In particular, SVG features like gradients, patterns, and text are not supported. The apparent vision is for vector

drawable artwork to be used mostly for things like action bar icons, where things like gradients and patterns are not necessary.

Android Studio Vector Asset Wizard

The primary way most developers will get vector drawable XML into their projects is via the Android Studio Vector Asset wizard. You can bring this up by right-clicking over the `res/` directory of your desired source set, and choosing New > Vector Asset from the context menu:

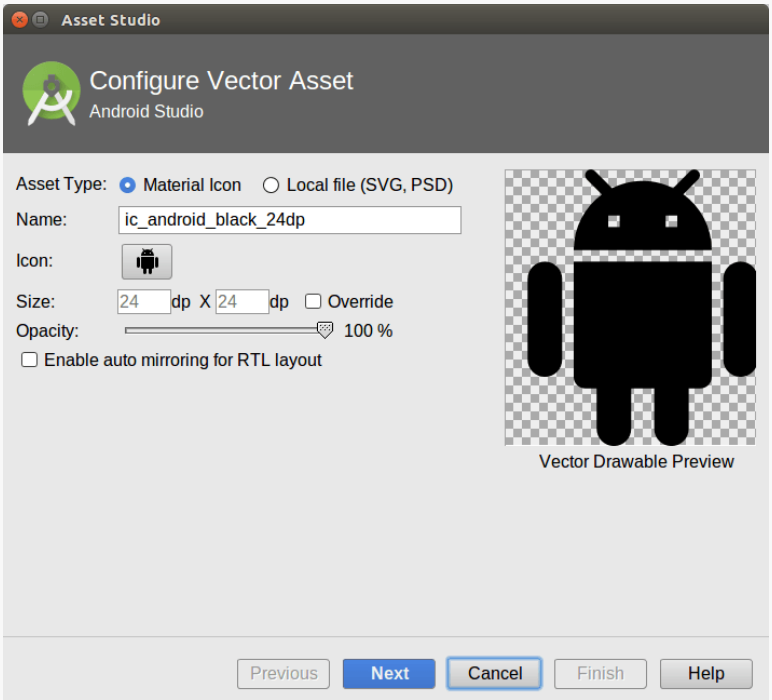

Figure 219: Android Studio Vector Asset Wizard

The "Asset Type" radio group gives you two sources of imagery: a subset of the official Material Design icons, or your own SVG or PSD file.

By default, the Material Icon radio button is selected. You can choose which icon to display by tapping the "Icon" button, which by default shows a rendition of the Android mascot. Tapping that button brings up a grid of icons for you to choose from:

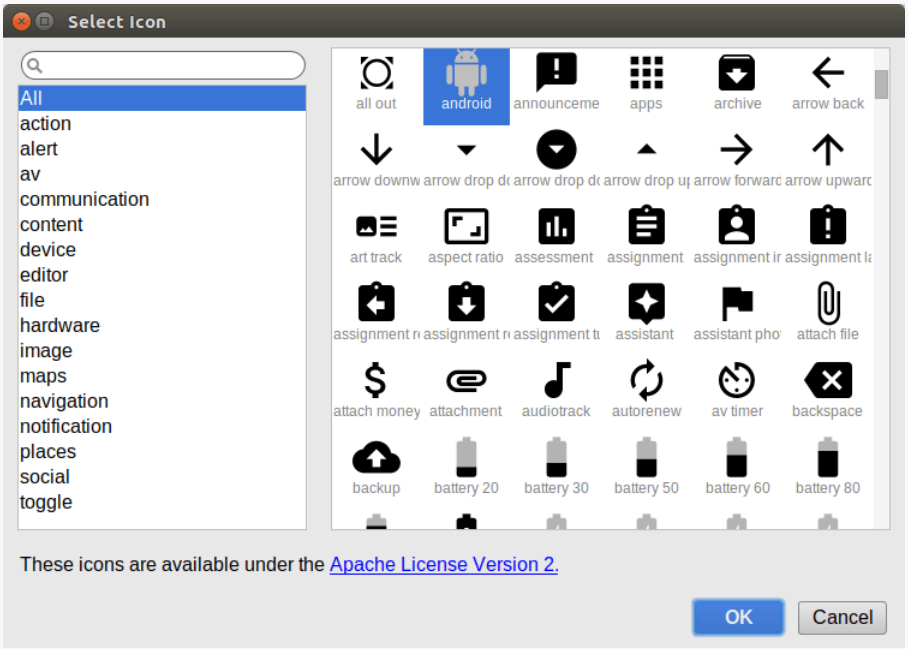

Figure 220: Android Studio Vector Asset Wizard, Material Icon Selector

You can browse by category or search by name to try to find the icon that you want from the library of available icons.

If you switch to the "Local file" radio button, the "Icon" button is replaced by a "Path" field, where you can pick the file that you wish to use.

By default, the Vector Asset wizard is trying to make action bar icon-sized images, 24dp square. You can override this by checking the "Override" checkbox and specifying your own size. The opacity slider allows you to indicate whether non-transparent pixels should be translucent (value from 0-99) or solid (100). If the image contains text or otherwise needs to be inverted for RTL languages, there is a checkbox to enable auto-mirroring support for that.

Also note that you can define the resource name, below where you chose the icon or SVG/PSD file. When importing a file, by default, the resource name will be the same as the base name of the file.

Clicking the "Next" button brings up a confirmation screen, where you can also change the module and source set if you perhaps brought up the wizard in the wrong spot:

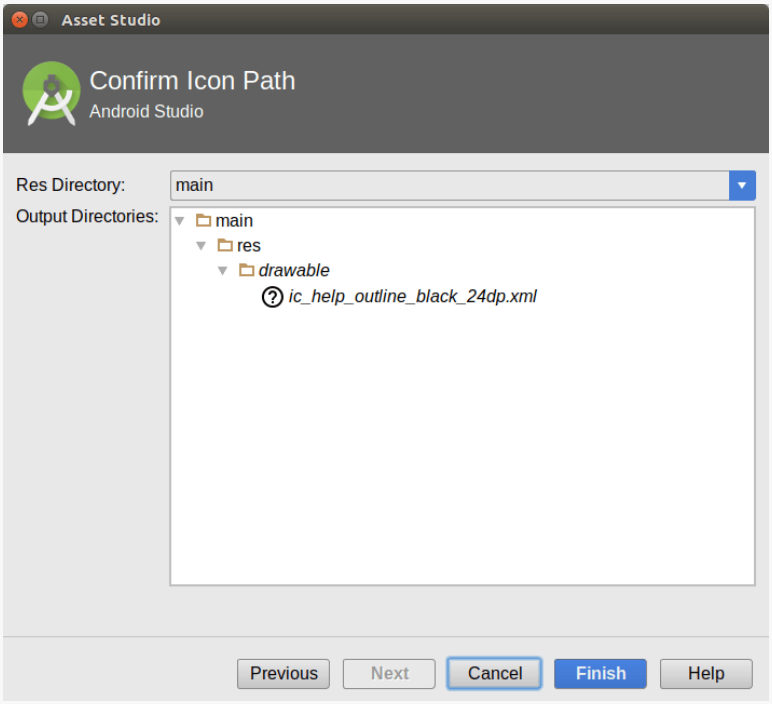

Figure 221: Android Studio Vector Asset Wizard, Confirmation Screen

Clicking Finish will import the resource and add it to `res/drawable/` in your project. When you build your project, if your `minSdkVersion` is below 21, the Android Gradle Plugin will generate PNG files to be used for those older devices. Note that these generated PNG files show up in your `build/` tree, not as part of your project source code.

The preview shown in the wizard should give you an indication if your SVG is being imported properly:

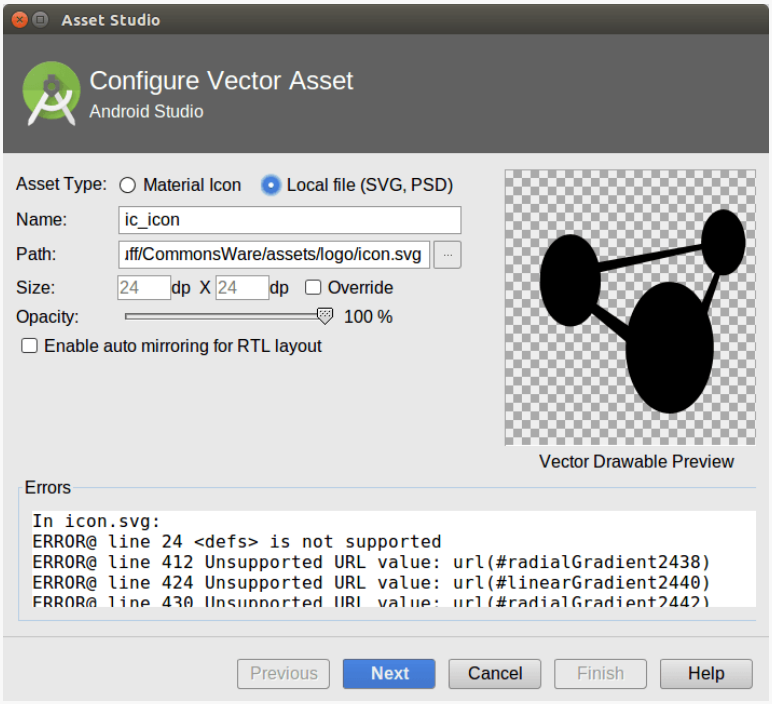

Figure 222: Android Studio Vector Asset Wizard, Showing Failed SVG Import

However, even if the preview turned out OK, be sure to test your app, both on Android 5.0+ and (if relevant) Android 4.4-and-older devices, to ensure that your artwork looks the way you want it to.

Other Tools

Juraj Novák maintains a separate Android SVG to vector drawable XML converter as a Web page. If you are running into problems with the Vector Asset wizard's import support, you might consider trying this site. It may give you better vector drawables directly, and it definitely gives you more indications about *why* your SVG may not convert properly.

Using the Artwork

You use vector drawable resources the same way that you use any other drawable resource. Under the covers, the Java class that handles rendering the artwork is `VectorDrawable`... on Android 5.0+.

If your `minSdkVersion` is below 21, and you want to use generated PNG files for the older devices, you need to add a line to the `defaultConfig` closure in your `android` closure in your module's `build.gradle` file:

```
apply plugin: 'com.android.application'

android {
    compileSdkVersion 24
    buildToolsVersion "24.0.1"

    defaultConfig {
        minSdkVersion 15
        targetSdkVersion 24
        vectorDrawables.generatedDensities = ['hdpi','xxhdpi']
    }
}
```

Specifically, you need to set the `generatedDensities` property on the `vectorDrawables` object to an array of strings, identifying the densities for which you want PNGs generated. As with other drawable resources, devices operating on other densities than those in your chosen list will re-sample icons from one of your provided densities. If you have few vector drawables, you could list more densities and not consume much APK space. The sample shown above settles for two: `hdpi` for mid-range devices and `xxhdpi` for high-end devices.

If your `minSdkVersion` is 21 or higher, though, you do not need the generated PNG files, as all devices that will run your app will be capable of using the vector drawables natively.

VectorDrawableCompat

In February 2016, Google released `support-vector-drawable`. This contains a `VectorDrawableCompat` class that supports vector drawables going back to API Level 7. Google also released `animated-vector-drawable`, which offers `AnimatedVectorDrawableCompat`, supported back to API Level 11. Getting these going is tricky because they are largely undocumented and have significant limitations.

The `Drawable/Vector` sample project demonstrates the use of `VectorDrawableCompat`. In its `res/drawables-nodpi/` directory, you will find a handful of vector drawable resources, culled from the Android Open Source Project. The sample app will show those in a pair of `ListView` widgets in tabs:

- One will use `VectorDrawableCompat` and will work for all API levels that the project supports (15 and higher, based on the project's `minSdkVersion`).
- One will use native vector drawable support. As you will see shortly, we are going to disable the normal PNG generation from the vector drawables, which means that this list will only show the icons on Android 5.0 and higher, not older devices.

Gradle Configuration

To make `VectorDrawableCompat` work, you need to make some changes to your Gradle build files:

- You need to be using at least version 1.5.0 of the Android Plugin for Gradle, as defined in your project's top-level `build.gradle` file
- You need to have a dependency on `com.android.support:support-vector-drawable` in your module's `build.gradle` file, akin to your other Android Support dependencies

If you are using a 1.5.x version of the Android Gradle Plugin:

- You need to configure `generatedDensities` in your `defaultConfig` closure, inside your `android` closure in your module's `build.gradle` file
- You need `additionalParameters "--no-version-vectors"` in an `aaptOptions` closure inside your `android` closure in your module's `build.gradle` file

Whereas if you are using 2.0.0 or higher of the Android Plugin for Gradle, you need `vectorDrawables.useSupportLibrary = true` in the `defaultConfig` closure of your `android` closure in your module's `build.gradle` file.

These latter steps disable the automatic generation of PNG files from the vector drawable resources that would ordinarily happen by default.

The sample project uses version 1.5.0 of the Android Gradle Plugin, and therefore it has the `generatedDensities` and the `additionalParameters "--no-version-vectors"` statements:

```
apply plugin: 'com.android.application'

dependencies {
    implementation 'io.karim:materialtabs:2.0.2'
    implementation 'com.android.support:support-v13:23.2.0'
```

```
    implementation 'com.android.support:support-vector-drawable:23.2.0'
}

android {
    compileSdkVersion 23
    buildToolsVersion '26.0.2'

    defaultConfig {
        minSdkVersion 15
        targetSdkVersion 22
        generatedDensities=[]
    }

    aaptOptions {
        additionalParameters "--no-version-vectors"
    }
}
```

(from Drawable/Vector/app/build.gradle)

Using a newer Android Gradle Plugin — 2.0.0 or higher – your `android` closure would have:

```
android {
   defaultConfig {
     vectorDrawables.useSupportLibrary = true
    }
}
```

Not generating PNG files saves us some disk space. On the other hand, now we are locked into using the vector drawable backport for these icons to be usable on older devices.

Use in Java

The sample app is cloned from another book sample, one that has a `ViewPager` with tabs. The activity simply sets up the `ViewPager` and tabs, using a `SampleAdapter` for the `ViewPager` contents. `SampleAdapter`, in turn, loads a `VectorFragment` or `VectorCompatFragment` into those tabs.

`VectorFragment` shows each of the icons in a row of a `ListView`, along with the resource name:

```
package com.commonsware.android.vector;
```

```
import android.app.ListFragment;
import android.os.Build;
import android.os.Bundle;
import android.view.View;
import android.view.ViewGroup;
import android.widget.ArrayAdapter;
import android.widget.ImageView;
import android.widget.TextView;

public class VectorFragment extends ListFragment {
  private static final Integer[] VECTORS={
    R.drawable.ic_account_circle,
    R.drawable.ic_check_circle_24px,
    R.drawable.ic_corp_badge,
    R.drawable.ic_corp_icon_badge,
    R.drawable.ic_corp_statusbar_icon,
    R.drawable.ic_eject_24dp,
    R.drawable.ic_expand_more_48dp,
    R.drawable.ic_folder_24dp,
    R.drawable.ic_more_items,
    R.drawable.ic_perm_device_info,
    R.drawable.ic_sd_card_48dp,
    R.drawable.ic_settings_24dp,
    R.drawable.ic_storage_48dp,
    R.drawable.ic_usb_48dp
  };

  @Override
  public void onViewCreated(View view,
                            Bundle savedInstanceState) {
    super.onViewCreated(view, savedInstanceState);

    setListAdapter(new VectorAdapter());
  }

  void applyIcon(ImageView icon, int resourceId) {
    if (Build.VERSION.SDK_INT>=Build.VERSION_CODES.LOLLIPOP) {
      icon.setImageResource(resourceId);
    }
  }

  class VectorAdapter extends ArrayAdapter<Integer> {
    VectorAdapter() {
      super(getActivity(), R.layout.row, R.id.title, VECTORS);
    }

    @Override
    public View getView(int position, View convertView, ViewGroup parent) {
```

```
      View row=super.getView(position, convertView, parent);
      ImageView icon=(ImageView)row.findViewById(R.id.icon);
      TextView title=(TextView)row.findViewById(R.id.title);

      applyIcon(icon, getItem(position));
      title.setText(getResources().getResourceName(getItem(position)));

      return(row);
    }
  }
}
```

(from Drawable/Vector/app/src/main/java/com/commonsware/android/vector/VectorFragment.java)

Specifically:

- Our array is a roster of the drawable resource IDs, named `VECTORS`
- `VectorFragment` uses a `VectorAdapter` to populate the `ListView`
- `VectorAdapter`, in `getView()`, uses `getResourceName()` on a `Resources` object to get the resource name associated with a resource ID, to show in a `TextView` in the row
- `VectorAdapter` delegates to `VectorFragment` and its `applyIcon()` method to populate the `ImageView` given a drawable resource ID

The `VectorFragment` implementation of `applyIcon()` simply calls `setImageResource()` on the `ImageView`, supplying the drawable resource ID. This works fine on Android 5.0 and higher, but it will fail on older devices, because older Android devices do not know natively about vector drawable resources. Hence, we only update the icon if we are on API Level 21 or higher.

So, on an Android 6.0 device, we get:

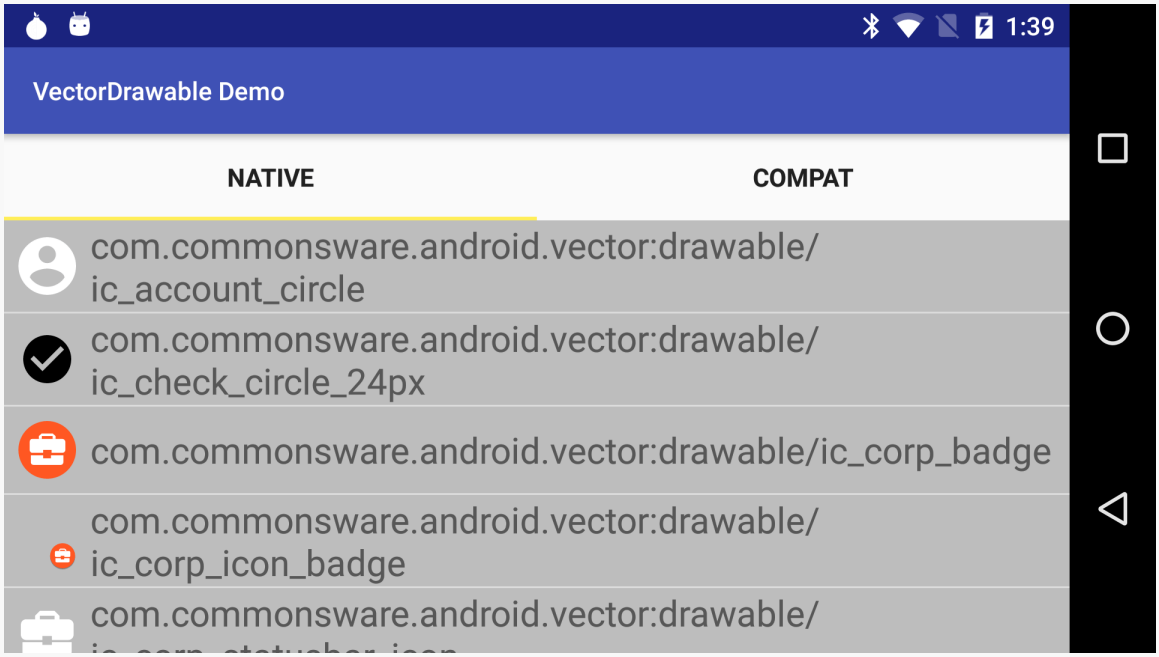

Figure 223: Vector Drawables, Native, Android 6.0

...while on an Android 4.4 device, we get:

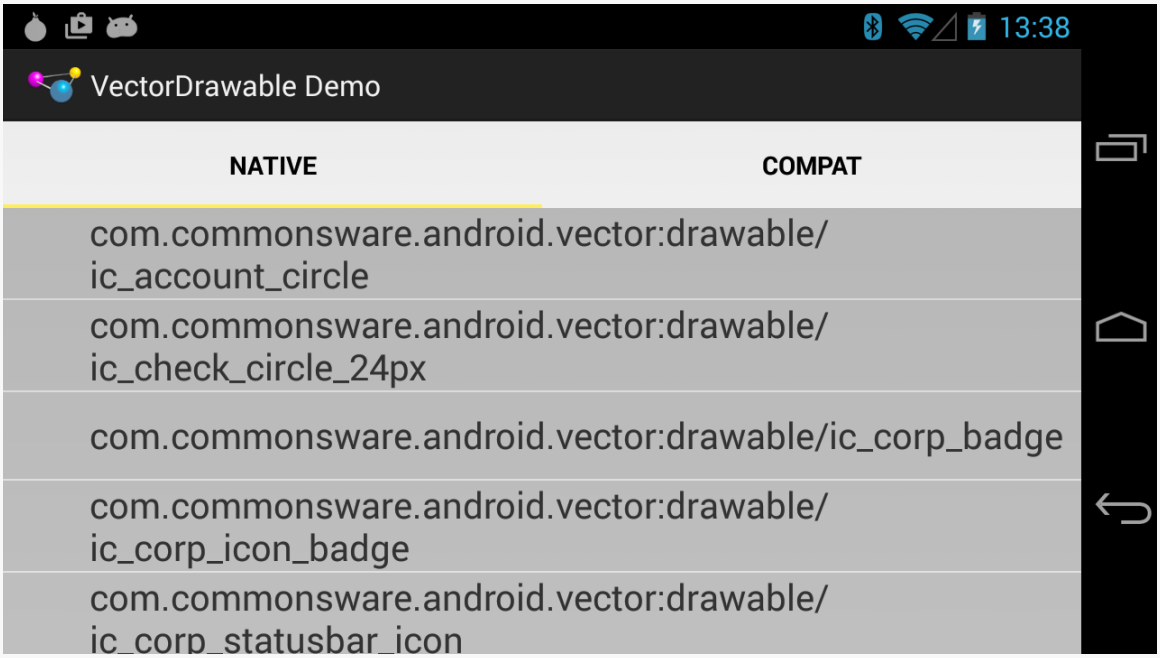

Figure 224: Vector Drawables, Missing on Android 4.4

`VectorCompatFragment` extends `VectorFragment` and simply overrides `applyIcon()`:

```
package com.commonsware.android.vector;

import android.graphics.drawable.Drawable;
import android.support.graphics.drawable.VectorDrawableCompat;
import android.widget.ImageView;

public class VectorCompatFragment extends VectorFragment {
  @Override
  void applyIcon(ImageView icon, int resourceId) {
    Drawable d=VectorDrawableCompat.create(getResources(),
      resourceId, null);

    icon.setImageDrawable(d);
  }
}
```

(from Drawable/Vector/app/src/main/java/com/commonsware/android/vector/VectorCompatFragment.java)

Here, we use `VectorDrawableCompat`, and its `static` `create()` method, to create a `Drawable` to apply to the `ImageView` via `setImageDrawable()`. `create()` takes three parameters:

- a `Resources` object
- a resource ID of a vector drawable
- an optional theme, or `null` to use the app's default theme

This approach works on all versions of Android supported by `VectorDrawableCompat`, which is API Level 7 and higher. However, on Android 5.0+ devices, `create()` will actually use a native vector drawable; the backport is only used on older devices.

The "Compat" tab of the Android 6.0 device and Android 4.4 device both show the icons:

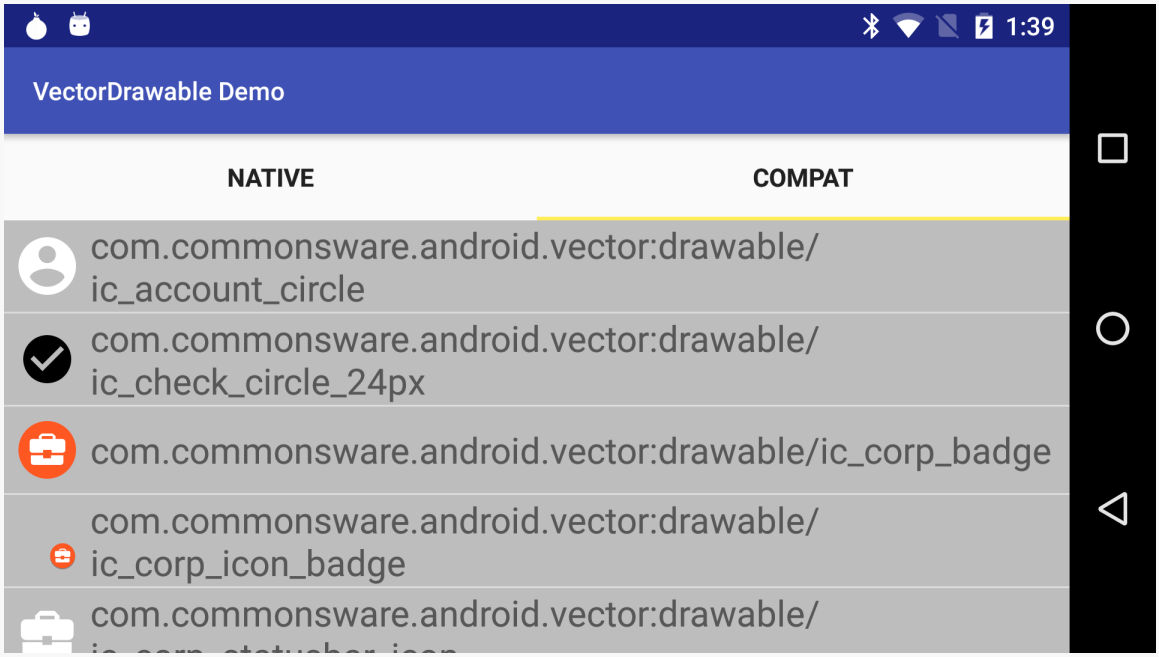

Figure 225: Vector Drawables, Loaded via VectorDrawableCompat, Android 6.0

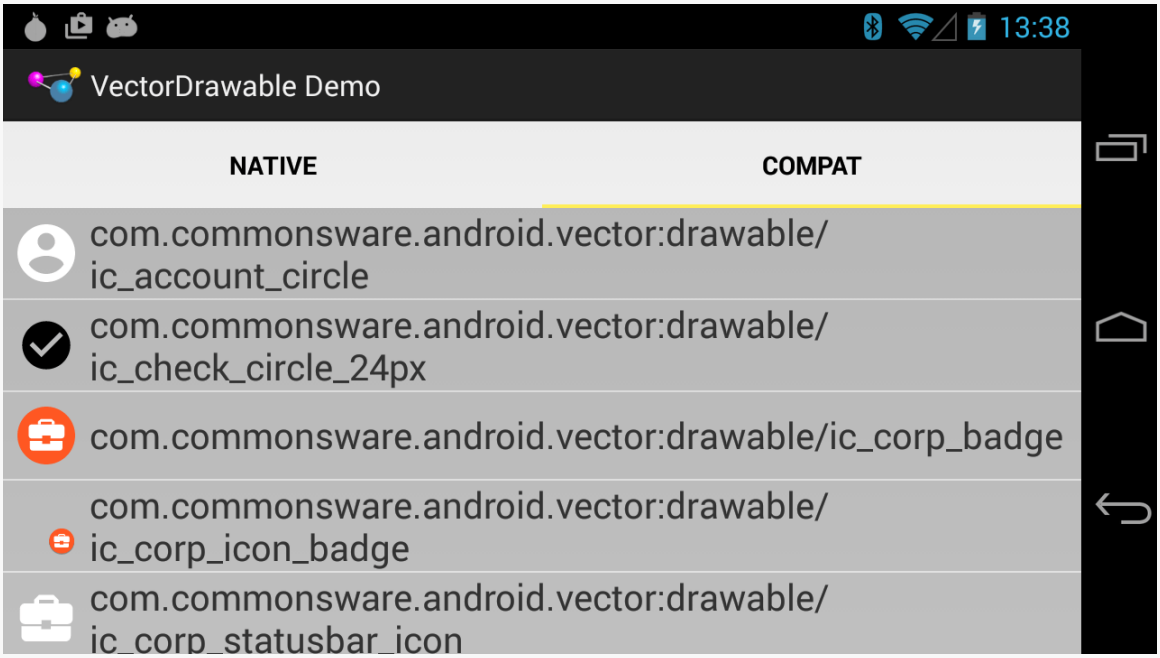

Figure 226: Vector Drawables, Loaded via VectorDrawableCompat, Android 4.4

Other VectorDrawable Backports

There are at least three independent backports, though, that you can try if you want to use the vector artwork directly on the older devices, rather than use PNGs generated from that vector artwork:

- https://github.com/wnafee/vector-compat
- https://github.com/a-student/BetterVectorDrawable
- https://github.com/telly/MrVector

Note that the last one was marked as deprecated, and the others may follow at some point, given that Google now has an official backport.

Tutorial #7 - Setting Up the Action Bar

Next up is to configure the action bar to our EmPubLite application.

This is a continuation of the work we did in the previous tutorial.

You can find the results of the previous tutorial and the results of this tutorial in the book's GitHub repository.

Starting in this tutorial, we will now begin editing Java source files. Some useful Android Studio shortcut key combinations are:

- Alt-Enter (Option-Return on macOS) for bringing up quick-fixes for the problem at the code where the cursor is.
- Ctrl-Alt-O (Command-Option-O on macOS) will organize your Java `import` statements, including removing unused imports.
- Ctrl-Alt-L (Command-Option-L on macOS) will reformat the Java or XML in the current editing window, in accordance with either the default styles in Android Studio or whatever you have modified them to in Settings.

Step #1: Adding Some Icons

We are going to need a couple of icons for our action bar items. Nowadays, the preferred approach for doing this is to start with vector drawables.

Right-click over the `res/` directory and choose New > "Vector Asset" from the context menu. This brings up the first page of the vector asset wizard:

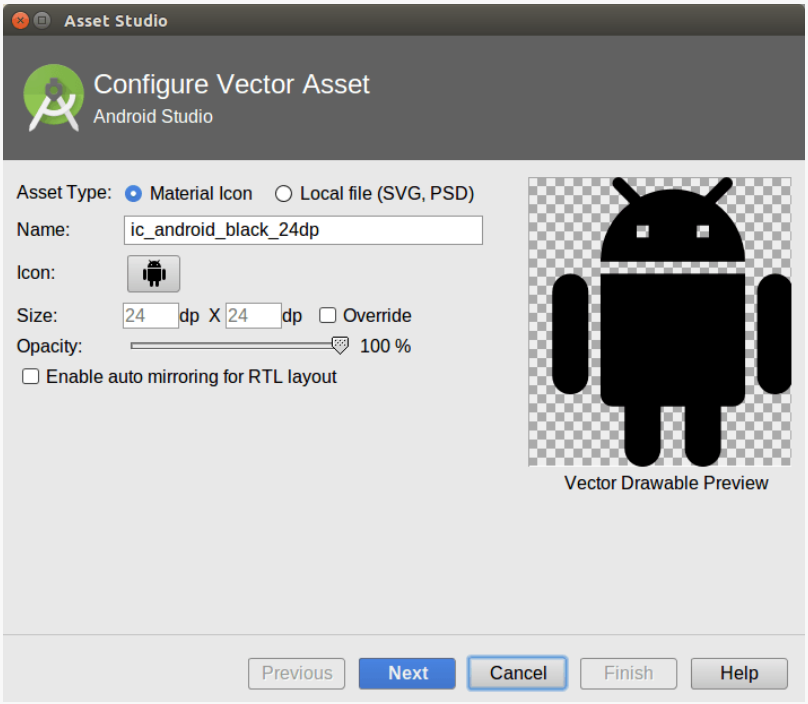

Figure 227: Android Studio Vector Asset Wizard, As Initially Launched

Click on the Icon button. This will bring up the material icon selector. In the search field, type `info`, then click on the "info outline" icon:

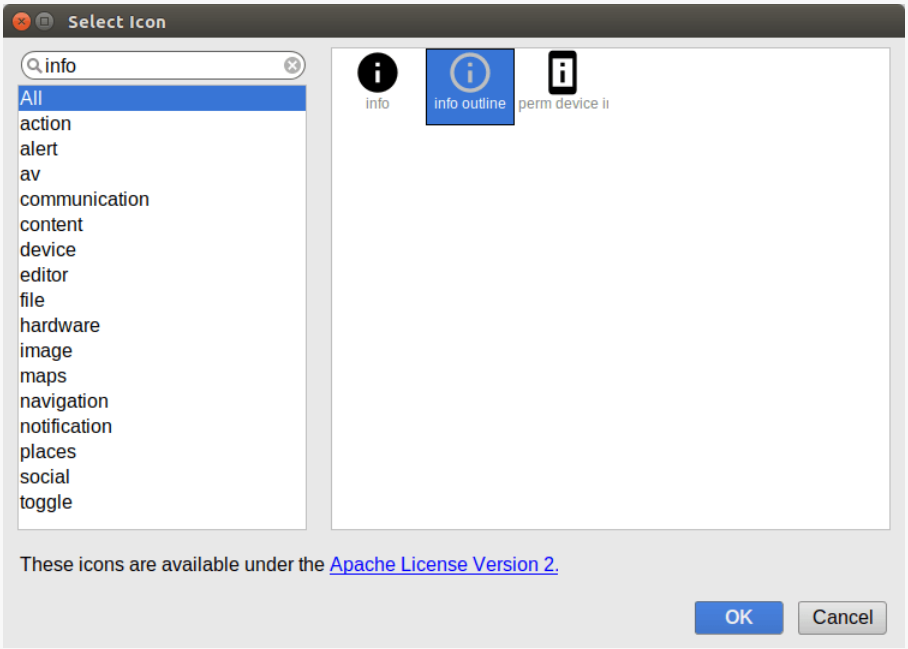

Figure 228: Android Studio Vector Asset Wizard, Material Icon Selector

Click "OK". This will update the name of the asset to `ic_info_outline_black_24dp`.

Click Next, then Finish, to add that icon as an XML file in `res/drawable/`.

Repeat that process to add a second vector asset, this time for "help outline" – you can search on `help` to quickly get to this icon.

Step #2: Defining Some Options

Next, we will add a couple of low-priority action items, for a help screen and an "about" screen.

Right click over the `res/` directory in your project, and choose New > "Android resource directory" from the context menu. This will bring up a dialog to let you create a new resource directory:

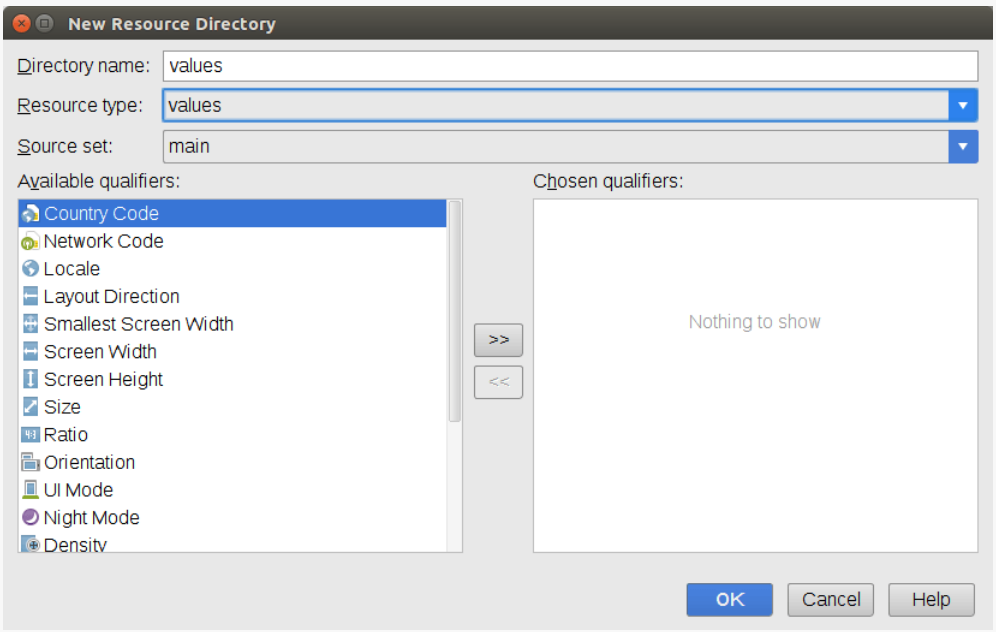

Figure 229: Android Studio New Resource Directory

Change the "Resource type" drop-down to be "menu", then click OK to create the directory.

Then, right-click over your new `res/menu/` directory and choose New > "Menu resource file" from the context menu. Fill in `options.xml` in the "New Menu Resource File" dialog:

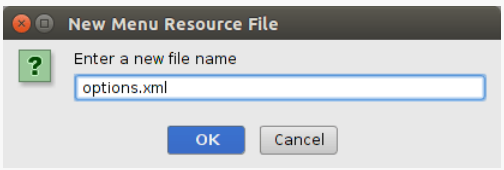

Figure 230: Android Studio New Menu Resource Dialog

Then click OK to create the file. It will open up into a menu editor:

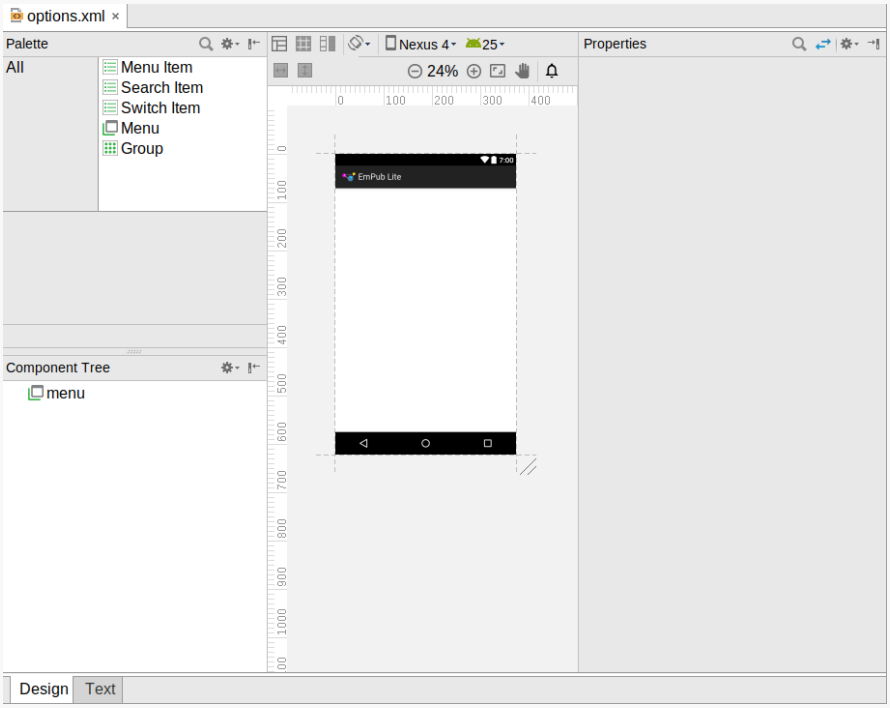

Figure 231: Android Studio Menu Resource Editor

Unfortunately, the drag-and-drop capabilities of this editor have many bugs. It will be simpler for you to switch to the Text sub-tab of the editor, into which you can paste the following content:

```
<?xml version="1.0" encoding="utf-8"?>
<menu xmlns:android="http://schemas.android.com/apk/res/android">

  <item
    android:id="@+id/help"
    android:icon="@drawable/ic_help_outline_black_24dp"
    android:title="@string/help">
  </item>
  <item
    android:id="@+id/about"
    android:icon="@drawable/ic_info_outline_black_24dp"
    android:title="@string/about">
  </item>

</menu>
```

(from EmPubLite-AndroidStudio/T7-ActionBar/EmPubLite/app/src/main/res/menu/options.xml)

If you prefer, you can view this file's contents in your Web browser via this GitHub link.

Also, you will need to add string resources for `help` and `about`, by adding appropriate `<string>` elements to your existing `res/values/strings.xml` file:

```
<resources>
  <string name="app_name">EmPub Lite</string>
  <string name="hint">Enter notes here</string>
  <string name="help">Help</string>
  <string name="about">About</string>
</resources>
```

(from EmPubLite-AndroidStudio/T7-ActionBar/EmPubLite/app/src/main/res/values/strings.xml)

If you prefer, you can view this file's contents in your Web browser via this GitHub link.

Step #3: Loading and Responding to Our Options

Simply defining `res/menu/options.xml` is insufficient. We need to actually tell Android to use what we defined in that file, and we need to add code to respond to when the user taps on our items.

To do that, you will need to add an `onCreateOptionsMenu()` method and an `onOptionsItemSelected()` method to `EmPubLiteActivity`, as follows:

```
  @Override
  public boolean onCreateOptionsMenu(Menu menu) {
    getMenuInflater().inflate(R.menu.options, menu);

    return(super.onCreateOptionsMenu(menu));
  }

  @Override
  public boolean onOptionsItemSelected(MenuItem item) {
    switch (item.getItemId()) {
      case R.id.about:
        return (true);

      case R.id.help:
        return (true);
    }
```

```
    return(super.onOptionsItemSelected(item));
  }
```

(from EmPubLite-AndroidStudio/T7-ActionBar/EmPubLite/app/src/main/java/com/commonsware/empublite/EmPubLiteActivity.java)

NOTE: Copying and pasting Java code may or may not work, depending on what you are using to read the book. For the PDF, some PDF viewers (e.g., Adobe Reader) should copy the code fairly well; others may do a much worse job. Reformatting the code with Ctrl-Alt-L (Command-Option-L on macOS) after pasting it in sometimes helps.

In `onCreateOptionsMenu()`, we are inflating `res/menu/options.xml` and pouring its contents into the supplied `Menu` object, which will be used by Android to populate our action bar.

In `onOptionsItemSelected()`, we examine the supplied `MenuItem` and route to different branches of a `switch` statement based upon the item's ID.

To get this to compile, you will need to add some imports as well:

```
import android.view.Menu;
import android.view.MenuItem;
```

(from EmPubLite-AndroidStudio/T7-ActionBar/EmPubLite/app/src/main/java/com/commonsware/empublite/EmPubLiteActivity.java)

Android Studio users can press Alt-Enter (Command-Return on macOS) with the cursor in a class reference that is missing its import to add that import.

Step #4: Supporting Older Devices

As was noted in the previous chapter, for our vector drawables to work properly on older devices, we need to add a line to our `app/build.gradle` file, identifying the particular screen densities for which we want PNG editions of our vector drawables.

So, add a `vectorDrawables.generatedDensities` line to the `defaultConfig` closure, resulting in an `app/build.gradle` file that looks something like:

```
apply plugin: 'com.android.application'

android {
    compileSdkVersion 25
    buildToolsVersion '26.0.2'
    defaultConfig {
        applicationId "com.commonsware.empublite"
```

```
        minSdkVersion 15
        targetSdkVersion 25
        versionCode 1
        versionName "1.0"
        testInstrumentationRunner "android.support.test.runner.AndroidJUnitRunner"
        vectorDrawables.generatedDensities = ['hdpi','xxhdpi']
    }
    buildTypes {
        release {
            minifyEnabled false
            proguardFiles getDefaultProguardFile('proguard-android.txt'), 'proguard-rules.pro'
        }
    }
}

repositories {
    maven {
        url "https://s3.amazonaws.com/repo.commonsware.com"
    }
}

dependencies {
    androidTestImplementation('com.android.support.test.espresso:espresso-core:2.2.2', {
        exclude group: 'com.android.support', module: 'support-annotations'
    })
    testImplementation 'junit:junit:4.12'
    implementation 'org.greenrobot:eventbus:3.0.0'
    implementation 'com.google.code.gson:gson:2.8.0'
    implementation 'com.squareup.retrofit2:converter-gson:2.1.0'
    implementation 'com.squareup.okhttp3:okhttp:3.4.1'
    implementation 'com.commonsware.cwac:security:0.8.0'
    implementation 'com.android.support:support-v13:25.3.0'
    implementation 'io.karim:materialtabs:2.0.5'
}
```

(from EmPubLite-AndroidStudio/T7-ActionBar/EmPubLite/app/build.gradle)

This will not have any immediate impact, as for Help and About, we are not actually using the icons. Those items are set to always be in the overflow. However, in later tutorials, we will add more action bar items, and some of those will be in the action bar proper and will have vector drawable icons. Furthermore, once you start using vector drawables, it is best to add the `generatedDensities` to your `build.gradle` file, so you are set once you really start using those vector drawables.

Step #5: Trying It Out

If you run this on an Android 4.4+ device or emulator, you should see a "..." icon on the action bar:

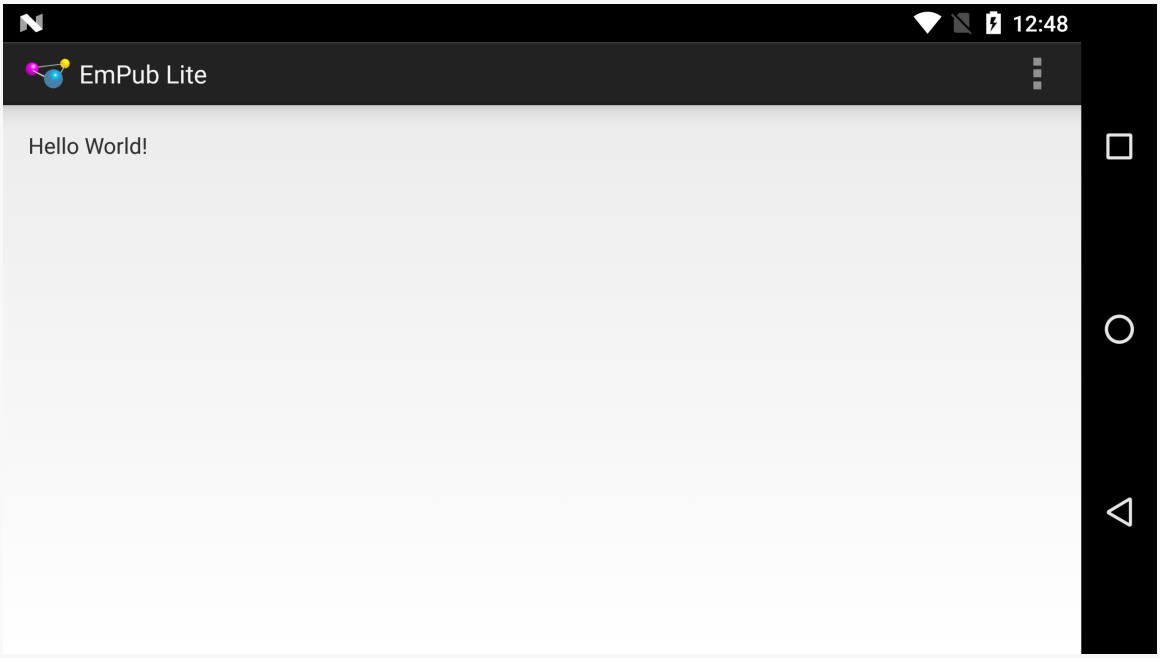

Figure 232: EmPubLite, Showing the ... Overflow Button

Pressing that brings up a menu showing our items:

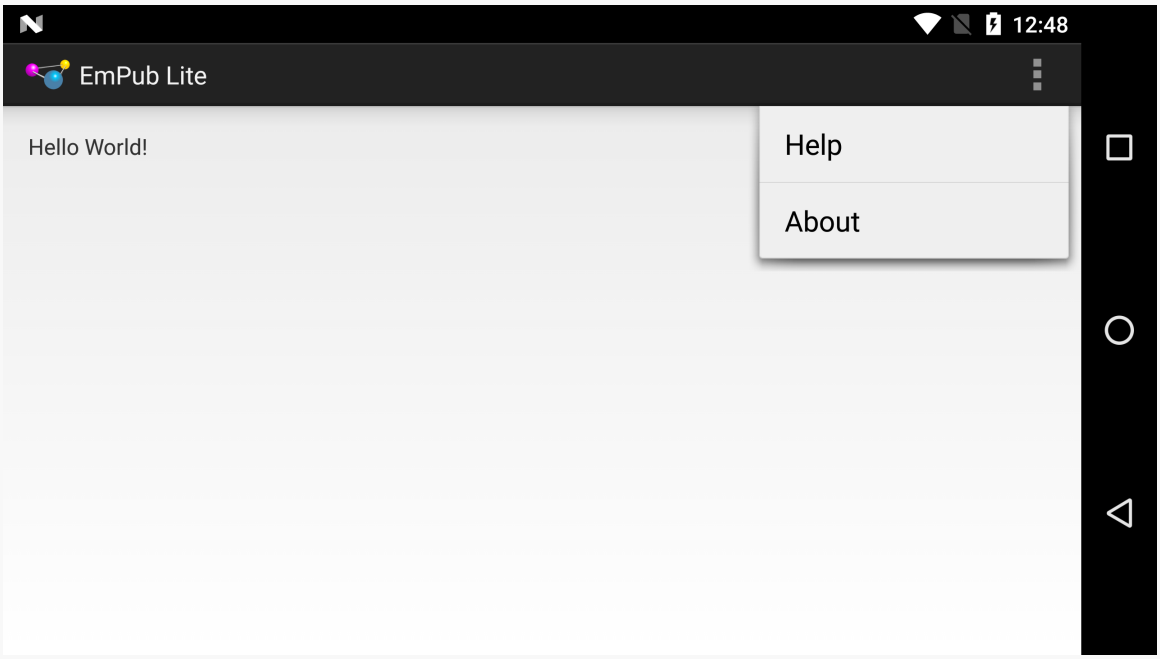

Figure 233: EmPubLite, Showing the Overflow Options

In Our Next Episode…

… we will define our first new activity on the tutorial project.

Android's Process Model

So far, we have been treating our activity like it is our entire application. Soon, we will start to get into more complex scenarios, involving multiple activities and other types of components, like services and content providers.

But, before we get into a lot of that, it is useful to understand how all of this ties into the actual OS itself. Android is based on Linux, and Linux applications run in OS processes. Understanding a bit about how Android and Linux processes inter-relate will be useful in understanding how our mixed bag of components work within these processes.

When Processes Are Created

A user installs your app, goes to their home screen's launcher, and taps on an icon representing your activity. Your activity dutifully appears on the screen.

Behind the scenes, what happened is that Android forked a copy of a process known as the `zygote`. As a result of the way your process is forked from the `zygote`, your process contains:

- A copy of the VM (Dalvik or ART), shared among all such processes via Linux copy-on-write memory sharing
- A copy of the Android framework classes, like `Activity` and `Button`, also shared via copy-on-write memory
- A copy of your own classes, loaded out of your APK
- Any objects created by you or the framework classes, such as the instance of your `Activity` subclass

BACK, HOME, and Your Process

Suppose that you have an app with just one activity. From the home screen's launcher, the user taps on the icon associated with your app's activity. Then, with your activity in the foreground, the user presses BACK.

At this point, the user is telling the OS that she is done with your activity. Control will return to whatever preceded that activity — in this case, the home screen's launcher.

You might think that this would cause your process to be terminated. After all, that is how most desktop operating systems work. Once the user closes the last window of the application, the process hosting that application is terminated.

However, that is not how Android works. Android will *keep* your process around, for a little while at least. This is done for speed and power: if the user happens to want to return to your app sooner rather than later, it is more efficient to simply bring up another copy of your activity again in the existing process than it is to go set up a completely new copy of the process. This does not mean that your process will live forever; we will discuss when your process will go away later in this chapter.

Now, instead of the user pressing BACK, let's say that the user pressed HOME instead. Visually, there is little difference: the home screen re-appears. Depending on the home screen implementation there may be a visible difference, as BACK might return to a launcher whereas HOME might return to something else on the home screen. However, in general, they feel like very similar operations.

The difference is what happens to your activity.

When the user presses BACK, your foreground activity is *destroyed*. We will get into more of what that means in the next chapter. However, the key feature is that the activity itself — the instance of your subclass of `Activity` – will never be used again, and hopefully is garbage collected.

When the user presses HOME, your foreground activity is *not* destroyed... at least, not immediately. It remains in memory. If the user launches your app again from the home screen launcher, and if your process is still around, Android will simply bring your existing activity instance back to the foreground, rather than having to create a brand-new one (as is the case if the user pressed BACK and destroyed your activity).

What HOME literally is doing is bringing the home screen activity back to the foreground, not otherwise directly affecting your process much.

Termination

Processes cannot live forever. They take up a chunk of RAM, for your classes and objects, and these mobile devices only have so much RAM to work with. Eventually, therefore, Android has to get rid of your process, to free up memory for other applications.

How long your process will stick around depends on a variety of factors, including:

- What else the device is doing, either in the foreground (user using apps) or in the background (e.g., automated checks for new email)
- How much memory the device has
- What is still running inside your process

Going back to the scenario from above, we have an application with a single activity launched from the home screen, where the user can return to the home screen either by pressing BACK or by pressing HOME. You might think that this makes no difference at all on when the process would be terminated, but that would be incorrect. Pressing HOME would keep the process around perhaps a bit longer than would pressing BACK.

Why?

When the user presses BACK, your one and only activity is destroyed. When the user presses HOME, your activity is not destroyed. Android will tend to keep processes around longer if they have active (i.e., not destroyed) components in them.

The key word there is "tend". Android's algorithms for determining when to get rid of what processes are baked into the OS and are, at best, lightly documented. There is evidence to suggest that other criteria, such as process age, are also taken into account, and so there may be times when a process that has an activity running (but not in the foreground) might be terminated where a process with no running activity might not. However, in general, processes with active (not destroyed) components will stick around a bit longer than processes without such components.

Foreground Means "I Love You"

Just because Android terminates processes to free up memory does not mean that it will terminate just any process to free up memory. A foreground process – the most common of which is a process that has an activity in the foreground – is the least likely of all to be terminated. In fact, you can pretty much assume that if Android has to kill off the foreground process, that the phone is very sick and will crash in a matter of moments.

(and, fortunately, that does not happen very often)

So, if you are in the foreground, you are safe. It is only when you are not in the foreground that you are at risk of having the process be terminated.

You and Your Heap

Processes take up RAM. A significant chunk of that RAM represents the objects you create (a.k.a., "the heap").

Those of you with significant Java backgrounds know that the Java VM loves RAM ("can't get enough of it!"). Java VMs routinely grab 64MB or 128MB of heap space upon creating the process and will grow as big as you wish to let them (e.g., `-Xmx` switch to the `java` command).

Android heap sizes are not that big, because Android is designed to run on mobile devices with constrained amounts of RAM.

Your heap limit may be as low as 16MB, though values in the 32-48MB range are more typical with current-generation devices. How much the heap limit will be depends a bit on what version of Android is on the device. It depends quite a lot, though, on the screen size, as bigger screens will tend to want to display bigger bitmap images, and bitmap images can consume quite a bit of RAM.

The key is that the heap is small, and (generally speaking) you cannot adjust it yourself. It is what it is. Small applications will rarely run into a problem with heap space, but larger applications might. We will discuss tools and techniques for measuring and coping with memory problems later in this book.

Activities and Their Lifecycles

An Android application will have multiple discrete UI facets. For example, a calendar application needs to allow the user to view the calendar, view details of a single event, edit an event (including adding a new one), and so forth. And on smaller-screen devices, like most phones, you may not have room to squeeze all of this on the screen at once.

To handle this, you can have multiple activities. Your calendar application may have one activity to display the calendar, another to add or edit an event, one to provide settings for how the calendar should work, another for your online help, etc. Some of these activities might be private to your app, while others might be able to be launched by third parties, such as your "launcher" activity being available to home screens.

All of this implies that one of your activities has the means to start up another activity. For example, if somebody clicks on an event from the view-calendar activity, you might want to show the view-event activity for that event. This means that, somehow, you need to be able to cause the view-event activity to launch and show a specific event (the one the user clicked upon).

This can be further broken down into two scenarios:

- You know what activity you want to launch, probably because it is another activity in your own application
- You have a reference to... something (e.g., a Web page), and you want your users to be able to do... something with it (e.g., view it), but you do not know up front what the options are

This chapter will cover both of those scenarios.

In addition, frequently it will be important for you to understand when activities are coming and going from the foreground, so you can automatically save or refresh data, etc. This is the so-called "activity lifecycle", and we will examine it in detail as well in this chapter.

Creating Your Second (and Third and…) Activity

Unfortunately, activities do not create themselves. On the positive side, this does help keep Android developers gainfully employed.

Hence, given a project with one activity, if you want a second activity, you will need to add it yourself. The same holds true for the third activity, the fourth activity, and so on.

The sample we will examine in this section is `Activities/Explicit`. Our first activity, `ExplicitIntentsDemoActivity`, started off as just the default activity code generated by the build tools. Now, though, its layout contains a `Button`:

```
<?xml version="1.0" encoding="utf-8"?>
<LinearLayout xmlns:android="http://schemas.android.com/apk/res/android"
  android:layout_width="match_parent"
  android:layout_height="match_parent"
  android:orientation="vertical">

  <Button
    android:layout_width="match_parent"
    android:layout_height="match_parent"
    android:textSize="20sp"
    android:text="@string/hello"
    android:onClick="showOther"/>

</LinearLayout>
```

(from Activities/Explicit/app/src/main/res/layout/main.xml)

That `Button` is tied to a `showOther()` method in our activity implementation, which we will examine shortly.

Defining the Class and Resources

To create your second (or third or whatever) activity, you first need to create the Java class. You need to create a new Java source file, containing a public Java class that extends `Activity` directly or indirectly. You have two basic ways of doing this:

- Just create the class and resources yourself
- Use the Android Studio new-activity wizard

To use the Android Studio new-activity wizard, right-click on your `app/src/main/` source set directory in the project explorer, and go into the New > Activity portion of the context menu. This will give you a submenu of available activity templates — mostly the same roster of templates that we saw back when we created the project in the first place.

If you choose one of those templates, you will be presented with a one-page wizard in which to provide the details for this activity:

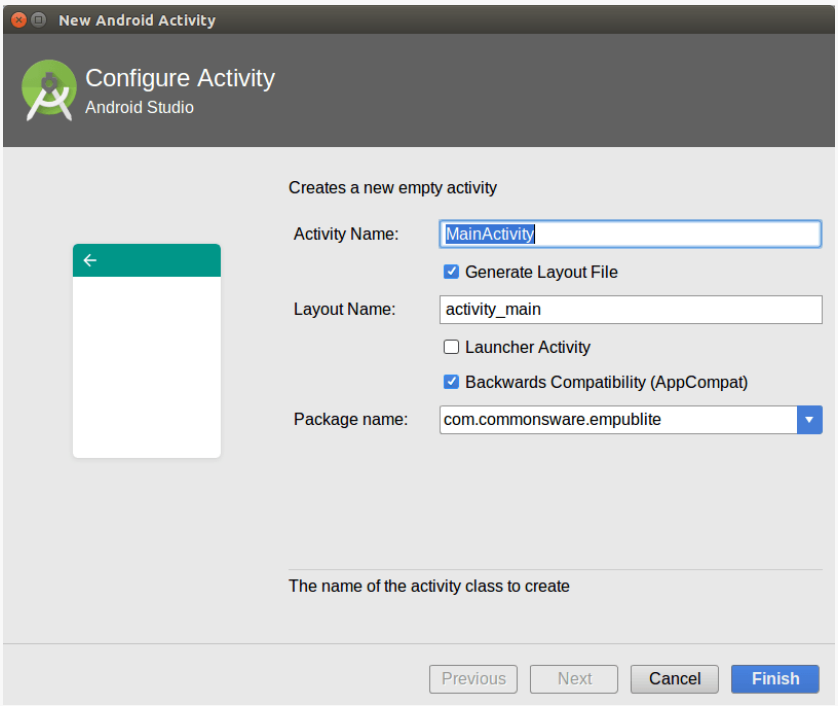

Figure 234: Android Studio New-Activity Wizard, Showing Empty Activity Template

What you see here will be based upon the template you chose (e.g., activity name, layout XML resource name) and will resemble those we saw back in the new-project wizard.

Clicking "Finish" will then create the activity's Java class, related resources (if any), and manifest entry.

Populating the Class and Resources

Once you have your stub activity set up, you can then add an `onCreate()` method to it (or edit an existing one created by the wizard), filling in all the details (e.g., `setContentView()`), just like you did with your first activity. Your new activity may need a new layout XML resource or other resources, which you would also have to create (or edit those created for you by the wizard).

In `Activities/Explicit`, our second activity is `OtherActivity`, with pretty much the standard bare-bones implementation:

```
package com.commonsware.android.exint;

import android.app.Activity;
import android.os.Bundle;

public class OtherActivity extends Activity {
  @Override
  public void onCreate(Bundle savedInstanceState) {
    super.onCreate(savedInstanceState);
    setContentView(R.layout.other);
  }
}
```

(from Activities/Explicit/app/src/main/java/com/commonsware/android/exint/OtherActivity.java)

and a similarly simple layout, `res/layout/other.xml`:

```
<?xml version="1.0" encoding="utf-8"?>
<LinearLayout xmlns:android="http://schemas.android.com/apk/res/android"
  android:layout_width="match_parent"
  android:layout_height="match_parent"
  android:orientation="vertical">

  <TextView
    android:layout_width="match_parent"
    android:layout_height="wrap_content"
    android:text="@string/other"
    android:textColor="#FFFF0000"
    android:textSize="20sp"/>

</LinearLayout>
```

(from Activities/Explicit/app/src/main/res/layout/other.xml)

Augmenting the Manifest

Simply having an activity implementation is not enough. We also need to add it to our `AndroidManifest.xml` file. This is automatically handled for you by the IDEs' respective new-activity wizards. However, if you created the activity "by hand", you will need to add its manifest element, and over time you will need to edit this element in many cases.

Adding an activity to the manifest is a matter of adding another `<activity>` element to the `<application>` element:

```
<?xml version="1.0" encoding="utf-8"?>
<manifest xmlns:android="http://schemas.android.com/apk/res/android"
  package="com.commonsware.android.exint"
  android:versionCode="1"
  android:versionName="1.0">

  <uses-sdk
    android:minSdkVersion="7"
    android:targetSdkVersion="11"/>

  <supports-screens
    android:largeScreens="true"
    android:normalScreens="true"
    android:smallScreens="true"/>

  <application
    android:icon="@drawable/ic_launcher"
    android:label="@string/app_name">
    <activity
      android:name="ExplicitIntentsDemoActivity"
      android:label="@string/app_name">
      <intent-filter>
        <action android:name="android.intent.action.MAIN"/>

        <category android:name="android.intent.category.LAUNCHER"/>
      </intent-filter>
    </activity>
    <activity android:name="OtherActivity"/>
  </application>

</manifest>
```

(from Activities/Explicit/app/src/main/AndroidManifest.xml)

You need the `android:name` attribute at minimum. Note that we do not include an `<intent-filter>` child element, as we did with the original activity has. For now, take it on faith that the original activity's `<intent-filter>` is what causes it to appear as a launchable activity in the home screen's launcher. We will get into more details of how that `<intent-filter>` works and when you might want your own in a later chapter.

Warning! Contains Explicit Intents!

An `Intent` encapsulates a request, made to Android, for some activity or other receiver to do something.

If the activity you intend to launch is one of your own, you may find it simplest to create an explicit `Intent`, naming the component you wish to launch. For example, from within your activity, you could create an `Intent` like this:

```
new Intent(this, HelpActivity.class);
```

This would stipulate that you wanted to launch the `HelpActivity`. `HelpActivity` would need to have a corresponding `<activity>` element in your `AndroidManifest.xml` file.

In `Activities/Explicit`, `ExplicitIntentsDemoActivity` has a `showOther()` method tied to its `Button` widget's `onClick` attribute. That method will use `startActivity()` with an explicit `Intent`, identifying `OtherActivity`:

```
package com.commonsware.android.exint;

import android.app.Activity;
import android.content.Intent;
import android.os.Bundle;
import android.view.View;

public class ExplicitIntentsDemoActivity extends Activity {
  @Override
  public void onCreate(Bundle savedInstanceState) {
    super.onCreate(savedInstanceState);
    setContentView(R.layout.main);
  }

  public void showOther(View v) {
    startActivity(new Intent(this, OtherActivity.class));
```

```
  }
}
```

(from Activities/Explicit/app/src/main/java/com/commonsware/android/exint/ExplicitIntentsDemoActivity.java)

Our launched activity shows the button:

Figure 235: The Explicit Intents Demo, As Launched

Clicking the button brings up the other activity:

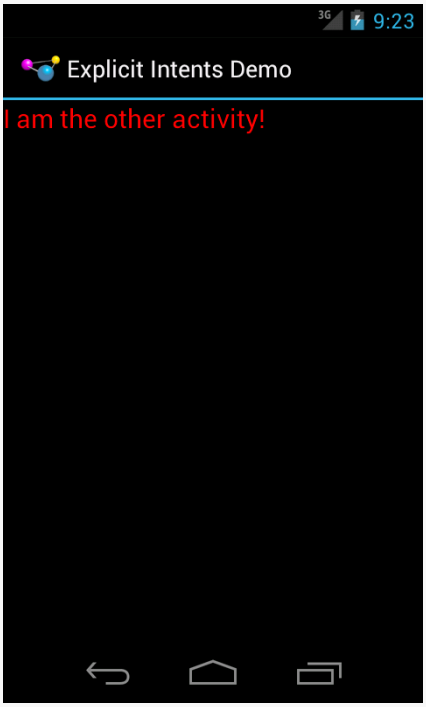

Figure 236: The Explicit Intents Demo, After Clicking the Button

Clicking BACK would return us to the first activity. In this respect, the BACK button in Android works much like the BACK button in your Web browser.

Using Implicit Intents

The explicit `Intent` approach works fine when the activity to be started is one of yours.

However, you can also start up activities from the operating system or third-party apps. In those cases, though, you will not have a Java `Class` object representing the other activity in your project, so you cannot use the `Intent` constructor that takes a `Class`.

Instead, you will use what are referred as the "implicit" `Intent` structure, which looks an *awful* lot like how the Web works.

If you have done any work on Web apps, you are aware that HTTP is based on verbs applied to URIs:

- We want to `GET` this image
- We want to `POST` to this script or controller
- We want to `PUT` to this REST resource
- Etc.

Android's implicit `Intent` model works much the same way, just with a *lot* more verbs.

For example, suppose you get a latitude and longitude from somewhere (e.g., body of a tweet, body of a text message). You decide that you want to display a map on those coordinates. There are ways that you can embed a Google Map directly in your app — and we will see how in a later chapter — but that is complicated and assumes the user wants Google Maps. It would be better if we could create some sort of generic "hey, Android, display an activity that shows a map for this location" request.

Or, in a simpler scenario: we get a URL to a Web page from some source (e.g., Web service call), and we want to open a Web browser on that page. This is illustrated in the `Activities/LaunchWeb` sample project.

We have a `LaunchDemo` activity that uses a layout containing a `EditText` widget and a `Button`, among other things:

```
<?xml version="1.0" encoding="utf-8"?>
<LinearLayout xmlns:android="http://schemas.android.com/apk/res/android"
  android:layout_width="match_parent"
  android:layout_height="match_parent"
  android:orientation="vertical">

  <EditText
    android:id="@+id/url"
    android:layout_width="match_parent"
    android:layout_height="wrap_content"
    android:hint="@string/url"
    android:inputType="textUri"/>

  <Button
    android:id="@+id/browse"
    android:layout_width="match_parent"
    android:layout_height="wrap_content"
    android:onClick="showMe"
    android:text="@string/show_me"/>

</LinearLayout>
```

(from Activities/LaunchWeb/app/src/main/res/layout/main.xml)

The `Button` is tied to a `showMe()` method on the activity itself, where we want to bring up a Web browser on the URL entered into the `EditText` widget:

```
package com.commonsware.android.activities;

import android.app.Activity;
import android.content.Intent;
import android.net.Uri;
import android.os.Bundle;
import android.view.View;
import android.widget.EditText;

public class LaunchDemo extends Activity {
  @Override
  public void onCreate(Bundle state) {
    super.onCreate(state);
    setContentView(R.layout.main);
  }

  public void showMe(View v) {
    EditText url=(EditText)findViewById(R.id.url);

    startActivity(new Intent(Intent.ACTION_VIEW,
                             Uri.parse(url.getText().toString())));
  }
}
```

(from Activities/LaunchWeb/app/src/main/java/com/commonsware/android/activities/LaunchDemo.java)

Here, we take the URL and convert it to a `Uri` via calling `Uri.parse()`. Then, we can use an action called `ACTION_VIEW` to try to display the desired Web page.

When launched, the user is presented with our data entry form:

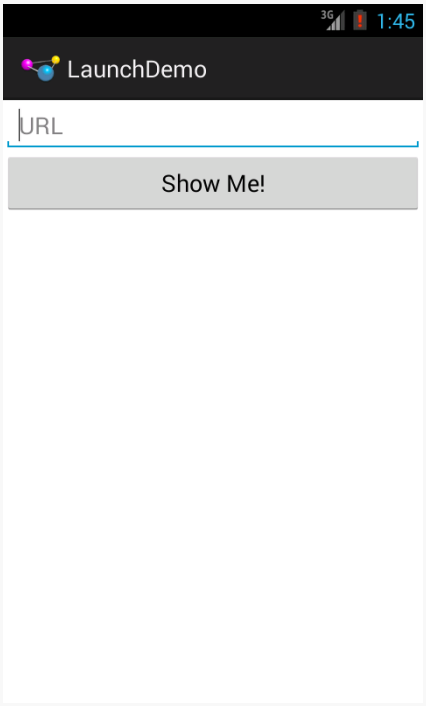

Figure 237: LaunchWeb Demo, As Initially Launched

We can fill in a URL:

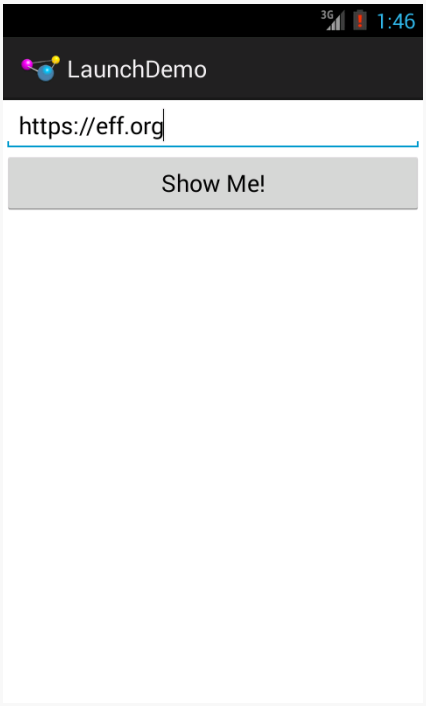

Figure 238: LaunchWeb Demo, After Data Entry

If the device has one app that responds to an `ACTION_VIEW` `Intent` on an `https:` scheme, clicking the "Show Me!" button will bring up that app, probably a Web browser:

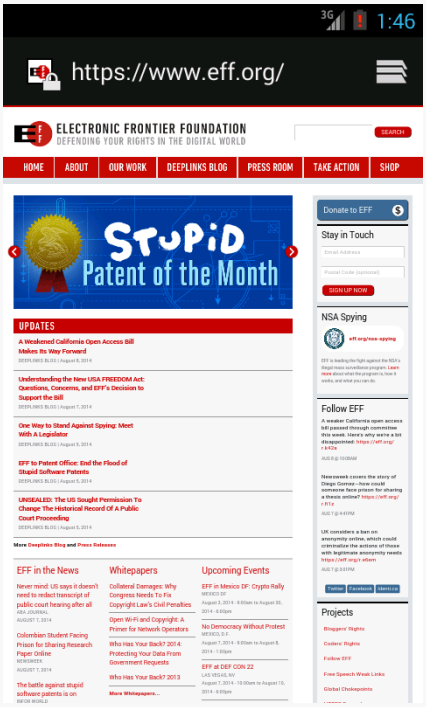

Figure 239: EFF Home Page, Launched from LaunchWeb

We will discuss what happens if there are no applications set up to handle this `Intent`, or if there is more than one, in a later chapter.

Where Do We Get These Uri Values?

In this example, we used `Uri.parse()` to parse an `https` URL. This is a typical approach for such URLs.

However, sometimes, what we want to view is on the device already, rather than being online. In those cases, we do not use `https`, or even `http`. Instead, we will use two other schemes: `file` and `content`.

The `file` scheme works more or less as it does with Web browsers. `file://` plus a path is a URL pointing to a file on the filesystem. We will get into working with files a bit later in the book. Given a `File` object, we can get the corresponding `Uri` via `Uri.fromFile()`.

The `content` scheme is for a `ContentProvider`. This is one of our Android components (along with activities, services, and broadcast receivers). A `content` `Uri` points to some content from that provider: a contact, a stream, a calendar entry, etc.

Usually, we get these as `Uri` values directly. If, somehow, you wind up with a `String` representation of a `content` `Uri`, `Uri.parse()` can turn that back into a `Uri`. We will get more into how to use a `ContentProvider` later in the book.

Extra! Extra!

Sometimes, we may wish to pass some data from one activity to the next. For example, we might have a `ListActivity` showing a collection of our model objects (e.g., books) and we have a separate `DetailActivity` to show information about a specific model object. Somehow, `DetailActivity` needs to know which model object to show.

One way to accomplish this is via `Intent` extras.

There is a series of `putExtra()` methods on `Intent` to allow you to supply key/value pairs of data to be bundled into the `Intent`. While you cannot pass arbitrary objects, most primitive data types are supported, as are strings and some types of lists. The next section will explain a bit more about what can go in an `Intent` extra.

Any activity can call `getIntent()` to retrieve the `Intent` used to start it up, and then can call various forms of `get... Extra()` (with the `...` indicating a data type) to retrieve any bundled extras.

For example, let's take a look at the `Activities/Extras` sample project.

This is mostly a clone of the `Activities/Explicit` sample from earlier in this chapter. However, this time, our first activity will pass an extra to the second:

```
package com.commonsware.android.extra;

import android.app.Activity;
import android.content.Intent;
import android.os.Bundle;
import android.view.View;

public class ExtrasDemoActivity extends Activity {
  @Override
  public void onCreate(Bundle savedInstanceState) {
    super.onCreate(savedInstanceState);
    setContentView(R.layout.main);
  }

  public void showOther(View v) {
```

```
    Intent other=new Intent(this, OtherActivity.class);

    other.putExtra(OtherActivity.EXTRA_MESSAGE, getString(R.string.other));
    startActivity(other);
  }
}
```

(from Activities/Extras/app/src/main/java/com/commonsware/android/extra/ExtrasDemoActivity.java)

We create the `Intent` as before, but then call `putExtra()`, supplying a key (a static string named `OtherActivity.EXTRA_MESSAGE`) and a value (the `R.string.other` string resource). Then, and only then, do we call `startActivity()`.

Our revised `OtherActivity` then retrieves that extra, along with the inflated `TextView` (via `findViewById()`) and pours that text in:

```
package com.commonsware.android.extra;

import android.app.Activity;
import android.os.Bundle;
import android.widget.TextView;

public class OtherActivity extends Activity {
  public static final String EXTRA_MESSAGE="msg";

  @Override
  public void onCreate(Bundle savedInstanceState) {
    super.onCreate(savedInstanceState);
    setContentView(R.layout.other);

    TextView tv=(TextView)findViewById(R.id.msg);

    tv.setText(getIntent().getStringExtra(EXTRA_MESSAGE));
  }
}
```

(from Activities/Extras/app/src/main/java/com/commonsware/android/extra/OtherActivity.java)

Visually, the result is the same. Functionally, the text to be shown is passed from one activity to the next.

Pondering Parcelable

As noted above, `Intent` extras cannot handle arbitrary objects. That is because, most of the time, `Intent` extras get passed across process boundaries. Even when you are

calling `startActivity()` to start up one of your own activities, that request passes from your process to a core OS process and back to your process. The `Intent` extras come along for the ride.

Hence, `Intent` extras need to be something that can be converted into a `byte` array, as part of the inter-process communication (IPC) that handles the passing around of `Intent` objects. You will see this come up in other flavors of Android IPC as well, such as remote services.

However, there are two ways in which you can try to make your own objects work as `Intent` extras.

One approach is to implement `Serializable` on your class. This is a classic Java construct, designed to allow instances of your class, and other `Serializable` objects your instances hold onto, to be serialized into files and later read back in.

Another approach is to implement `Parcelable` on your class. This is an Android construct, one that is very similar to `Serializable`. However, `Serializable` is designed for *durable* storage of objects, where the file might be read back in months or years later. As such, `Serializable` has to deal with possible changes to the Java code implementing those classes, and as such needs to have hooks to help with converting old, saved objects into new objects. This adds overhead. `Parcelable` is only concerned with converting objects into `byte` arrays to pass across process boundaries. It can make the simplifying assumption that the class definition is not changing from when the object is turned into bytes and when the bytes are turned back into an object. As a result, `Parcelable` is faster than `Serializable` for Android's IPC use.

You are welcome to implement `Parcelable` on your own classes if you wish, at which point they can be passed around via `Intent` extras. Beyond that, though, any Java classes you see in the Android JavaDocs that implement `Parcelable` can be put into `Intent` extras. So, for example, `Uri` implements `Parcelable`, and so you can put a `Uri` into an `Intent` extra. Not everything in the Android SDK is `Parcelable`, but some key classes like `Uri` are `Parcelable`.

A lot more detail on `Parcelable`, including how you can implement it on your own classes, appears later in this book.

Asynchronicity and Results

Note that `startActivity()` is asynchronous. The other activity will not show up until sometime after you return control of the main application thread to Android.

Normally, this is not much of a problem. However, sometimes one activity might start another, where the first activity would like to know some "results" from the second. For example, the second activity might be some sort of "chooser", to allow the user to pick a file or contact or song or something, and the first activity needs to know what the user chose. With `startActivity()` being asynchronous, it is clear that we are not going to get that sort of result as a return value from `startActivity()` itself.

To handle this scenario, there is a separate `startActivityForResult()` method. While it too is asynchronous, it allows the newly-started activity to supply a result (via a `setResult()` method) that is delivered to the original activity via an `onActivityResult()` method. We will examine `startActivityForResult()` in greater detail in a later chapter.

Schroedinger's Activity

An activity, generally speaking, is in one of four states at any point in time:

1. *Active*: the activity was started by the user, is running, and is in the foreground. This is what you are used to thinking of in terms of your activity's operation.
2. *Paused*: the activity was started by the user, is running, and is visible, but another activity is overlaying part of the screen. During this time, the user can see your activity but may not be able to interact with it. This is a relatively uncommon state, as most activities are set to fill the screen, not have a theme that makes them look like some sort of dialog box.
3. *Stopped*: the activity was started by the user, is running, but it is hidden by other activities that have been launched or switched to.
4. *Dead*: the activity was destroyed, perhaps due to the user pressing the BACK button.

Life, Death, and Your Activity

Android will call into your activity as the activity transitions between the four states listed above.

Note that for all of these, you should chain upward and invoke the superclass' edition of the method, or Android may raise an exception.

`onCreate()` and `onDestroy()`

We have been implementing `onCreate()` in all of our `Activity` subclasses in all the examples. This will get called in two primary situations:

- When the activity is first started (e.g., since a system restart), `onCreate()` will be invoked with a `null` parameter.
- If the activity undergoes what we refer to as a "configuration change", such as the screen being rotated, by default your activity will be re-created and `onCreate()` will be called. We will discuss this scenario in greater detail later in this book.

Here is where you initialize your user interface and set up anything that needs to be done once, regardless of how the activity gets used.

On the other end of the lifecycle, `onDestroy()` may be called when the activity is shutting down, such as because the activity called `finish()` (which "finishes" the activity) or the user presses the BACK button. Hence, `onDestroy()` is mostly for cleanly releasing resources you obtained in `onCreate()` (if any), plus making sure that anything you started up outside of lifecycle methods gets stopped, such as background threads.

Bear in mind, though, that `onDestroy()` may not be called. This would occur in a few circumstances:

- You crash with an unhandled exception
- The user force-stops your application, such as through the Settings app
- Android has an urgent need to free up RAM (e.g., to handle an incoming phone call), wants to terminate your process, and cannot take the time to call all the lifecycle methods

Hence, `onDestroy()` is very likely to be called, but it is not guaranteed.

Also, bear in mind that it may take a long time for `onDestroy()` to be called. It is called quickly if the user presses BACK to finish the foreground activity. If, however, the user presses HOME to bring up the home screen, your activity is not immediately destroyed. `onDestroy()` will not be called until Android does decide to gracefully terminate your process, and that could be seconds, minutes, or hours later.

`onStart()`, `onRestart()`, and `onStop()`

An activity can come to the foreground either because it is first being launched, or because it is being brought back to the foreground after having been hidden (e.g., by another activity, by an incoming phone call).

The `onStart()` method is called in either of those cases. The `onRestart()` method is called in the case where the activity had been stopped and is now restarting.

Conversely, `onStop()` is called when the activity is about to be stopped. It too may not be called, for the same reasons that `onDestroy()` would not be called. However, `onStop()` is usually called fairly quickly after the activity is no longer visible, so the odds that `onStop()` will be called are even higher than that of `onDestroy()`.

`onPause()` and `onResume()`

The `onResume()` method is called just before your activity comes to the foreground, either after being initially launched, being restarted from a stopped state, or after a pop-up dialog (e.g., incoming call) is cleared. This is a great place to refresh the UI based on things that may have occurred since the user last was looking at your activity. For example, if you are polling a service for changes to some information (e.g., new entries for a feed), `onResume()` is a fine time to both refresh the current view and, if applicable, kick off a background thread to update the view (e.g., via a `Handler`).

Conversely, anything that takes over user input — mostly, the activation of another activity — will result in your `onPause()` being called. Here, you should undo anything you did in `onResume()`, such as stopping background threads, releasing any exclusive-access resources you may have acquired (e.g., camera), and the like.

Once `onPause()` is called, Android reserves the right to kill off your activity's process at any point. Hence, you should not be relying upon receiving any further events.

So, what is the difference between `onPause()` and `onStop()`? If an activity comes to the foreground that fills the screen, your current foreground activity will be called with `onPause()` and `onStop()`. If, however, an activity comes to the foreground that does *not* fill the screen, your current foreground activity will only be called with `onPause()`, as it is still visible.

Stick to the Pairs

If you initialize something in `onCreate()`, clean it up in `onDestroy()`.

If you initialize something in `onStart()`, clean it up in `onStop()`.

If you initialize something in `onResume()`, clean it up in `onPause()`.

In other words, stick to the pairs. For example, do not initialize something in `onStart()` and try to clean it up in `onPause()`, as there are scenarios where `onPause()` may be called multiple times in succession (i.e., user brings up a non-full-screen activity, which triggers `onPause()` but not `onStop()`, and hence not `onStart()`).

Which pairs of lifecycle methods you choose is up to you, depending upon your needs. You may decide that you need two pairs (e.g., `onCreate()`/`onDestroy()` and `onResume()`/`onPause()`). Just do not mix and match between them.

When Activities Die

So, what gets rid of an activity? What can trigger the chain of events that results in `onDestroy()` being called?

First and foremost, when the user presses the BACK button, the foreground activity will be destroyed, and control will return to the previous activity in the user's navigation flow (i.e., whatever activity they were on before the now-destroyed activity came to the foreground).

You can accomplish the same thing by calling `finish()` from your activity. This is mostly for cases where some other UI action would indicate that the user is done with the activity (e.g., the activity presents a list for the user to choose from — clicking on a list item might close the activity). However, please do not artificially add your own "exit", "quit", or other menu items or buttons to your activity — just allow the user to use normal Android navigation options, such as the BACK button.

If none of your activities are in the foreground any more, your application's process is a candidate to be terminated to free up RAM. As noted earlier, depending on circumstances, Android may or may not call `onDestroy()` in these cases (`onPause()` and `onStop()` would have been called when your activities left the foreground).

If the user causes the device to go through a "configuration change", such as switching between portrait and landscape, Android's default behavior is to destroy your current foreground activity and create a brand new one in its place. We will cover this more in a later chapter.

And, if your activity has an unhandled exception, your activity will be destroyed, though Android will not call any more lifecycle methods on it, as it assumes your activity is in an unstable state.

Walking Through the Lifecycle

To see when these various lifecycle methods get called, let's examine the `Activities/Lifecycle` sample project.

This project is the same as the `Activities/Extras` project, except that our two activities no longer inherit from `Activity` directly. Instead, we introduce a `LifecycleLoggingActivity` as a base class and have our activities inherit from it:

```
package com.commonsware.android.lifecycle;

import android.app.Activity;
import android.os.Bundle;
import android.util.Log;

public class LifecycleLoggingActivity extends Activity {
  @Override
  public void onCreate(Bundle savedInstanceState) {
    super.onCreate(savedInstanceState);

    Log.d(getClass().getSimpleName(), "onCreate()");
  }

  @Override
  public void onRestart() {
    super.onRestart();

    Log.d(getClass().getSimpleName(), "onRestart()");
  }
```

```
  @Override
  public void onStart() {
    super.onStart();

    Log.d(getClass().getSimpleName(), "onStart()");
  }

  @Override
  public void onResume() {
    super.onResume();

    Log.d(getClass().getSimpleName(), "onResume()");
  }

  @Override
  public void onPause() {
    Log.d(getClass().getSimpleName(), "onPause()");

    super.onPause();
  }

  @Override
  public void onStop() {
    Log.d(getClass().getSimpleName(), "onStop()");

    super.onStop();
  }

  @Override
  public void onDestroy() {
    Log.d(getClass().getSimpleName(), "onDestroy()");

    super.onDestroy();
  }
}
```

(from Activities/Lifecycle/app/src/main/java/com/commonsware/android/lifecycle/LifecycleLoggingActivity.java)

All `LifecycleLoggingActivity` does is override each of the lifecycle methods mentioned above and emit a debug line to Logcat indicating who called what.

When we first launch the application, our first batch of lifecycle methods is invoked, in the expected order:

```
04-01 11:47:21.437: D/ExplicitIntentsDemoActivity(1473): onCreate()
```

```
04-01 11:47:21.827: D/ExplicitIntentsDemoActivity(1473): onStart()
04-01 11:47:21.827: D/ExplicitIntentsDemoActivity(1473): onResume()
```

If we click the button on the first activity to start up the second, we get:

```
04-01 11:47:54.776: D/ExplicitIntentsDemoActivity(1473): onPause()
04-01 11:47:54.877: D/OtherActivity(1473): onCreate()
04-01 11:47:54.947: D/OtherActivity(1473): onStart()
04-01 11:47:54.974: D/OtherActivity(1473): onResume()
04-01 11:47:55.347: D/ExplicitIntentsDemoActivity(1473): onStop()
```

Notice that our first activity is paused before the second activity starts up, and that `onStop()` is delayed on the first activity until after the second activity has appeared.

If we press the BACK button on the second activity, returning to the first activity, we see:

```
04-01 11:48:54.807: D/OtherActivity(1473): onPause()
04-01 11:48:54.857: D/ExplicitIntentsDemoActivity(1473): onRestart()
04-01 11:48:54.857: D/ExplicitIntentsDemoActivity(1473): onStart()
04-01 11:48:54.857: D/ExplicitIntentsDemoActivity(1473): onResume()
04-01 11:48:55.257: D/OtherActivity(1473): onStop()
04-01 11:48:55.257: D/OtherActivity(1473): onDestroy()
```

Notice how, once again, going onto the screen happens in between `onPause()` and `onStop()` of the activity leaving the screen. Also notice that `onDestroy()` is called immediately after `onStop()`, because the activity was finished via the BACK button.

If we now press the HOME button, to bring the home screen activity to the foreground, we see:

```
04-01 11:50:30.347: D/ExplicitIntentsDemoActivity(1473): onPause()
04-01 11:50:32.227: D/ExplicitIntentsDemoActivity(1473): onStop()
```

There is a delay between `onPause()` and `onStop()` as the home screen does its display work, and there is no `onDestroy()`, because the application is still running and nothing finished the activity. Eventually, the device will terminate our process, and if that happens normally, we would see the `onDestroy()` Logcat message.

Recycling Activities

Let us suppose that we have three activities, named A, B, and C. A starts up an instance of B based on some user input, and B later starts up an instance of C through some more user input.

Our "activity stack" is now A-B-C, meaning that if we press BACK from C, we return to B, and if we press BACK from B, we return to A.

Now, let's suppose that from C, we wish to navigate back to A. For example, perhaps the user pressed the icon on the left of our action bar, and we want to return to the "home activity" as a result, and in our case that happens to be A. If C calls `startActivity()`, specifying A, we wind up with an activity stack that is A-B-C-A.

That's because starting an activity, by default, creates a new instance of that activity. So, now we have two independent copies of A.

Sometimes, this is desired behavior. For example, we might have a single `ListActivity` that is being used to "drill down" through a hierarchical data set, like a directory tree. We might elect to keep starting instances of that same `ListActivity`, but with different extras, to show each level of that hierarchy. In this case, we would want independent instances of the activity, so the BACK button behaves as the user might expect.

However, when we navigate to the "home activity", we may not want a separate instance of A.

How to address this depends a bit on what you want the activity stack to look like after navigating to A.

If you want an activity stack that is B-C-A — so the existing copy of A is brought to the foreground, but the instances of B and C are left alone — then you can add `FLAG_ACTIVITY_REORDER_TO_FRONT` to your `Intent` used with `startActivity()`:

```
Intent i=new Intent(this, HomeActivity.class);

i.setFlags(Intent.FLAG_ACTIVITY_REORDER_TO_FRONT);
startActivity(i);
```

If, instead, you want an activity stack that is just A — so if the user presses BACK, they exit your application — then you would add two flags: `FLAG_ACTIVITY_CLEAR_TOP` and `FLAG_ACTIVITY_SINGLE_TOP`:

```
Intent i=new Intent(this, HomeActivity.class);

i.setFlags(Intent.FLAG_ACTIVITY_CLEAR_TOP | Intent.FLAG_ACTIVITY_SINGLE_TOP);
startActivity(i);
```

This will finish all activities in the stack between the current activity and the one you are starting — in our case, finishing C and B.

Application: Transcending the Activity

`Activity` inherits from a class named `Context`. Many of the methods that we are calling on our activities, like `startActivity()`, are inherited from `Context`.

However, `Activity` is not the only relevant subclass of `Context`. We will see `Service` later in the book, for example. And sometimes we will see plain `Context` objects, such as when we cover `BroadcastReceiver` later in the book.

Another `Context` of note is `Application`. An instance of `Application` is created when our app starts up. The `Application` instance is a natural singleton; there should be exactly one instance of `Application` in our process.

Normally, this singleton is an instance of `Application` itself. However, we can subclass `Application` if we wish, then include a reference to our custom application class in an `android:name` attribute on the `<application>` element in the manifest. Then, when Android starts up our app, it will create an instance of our designated `Application` subclass, rather than creating an instance of the ordinary `Application` class.

We can retrieve the `Application` object at any point by calling `getApplicationContext()` on any `Context` object. `getApplicationContext()` will return a `Context`; if we need to reference `Application` or our specific `Application` subclass, we need to down-cast the returned `Context` to the appropriate type.

We can use `Application` in a few ways in Android apps.

First and foremost, if we need to hold onto some other object in a `static` data member, and that other object needs a `Context`, we *really* want it to be using the

`Application`, not an `Activity`, `Service`, etc. Because `Application` is a singleton, it is effectively "pre-leaked". We cannot somehow leak it further by having another indirect `static` reference to it. In contrast, suppose we have a `static` data member holding onto an `Activity`. Now, when that `Activity` is destroyed, it (and all it holds, like widgets and listeners) cannot be garbage-collected. This represents a memory leak.

You could even take it one step further and have the `Application` manage this static data, rather than using separate singletons. There are pros and cons to this approach, but on the whole Google is not a big fan of it. That being said, `Application` has an `onCreate()` that is called shortly after it is instantiated, and your subclass of `Application` could override that and use it to initialize some "global" data.

However, while the JavaDocs indicate that there is an `onTerminate()` method on `Application` — suggesting that we find out when the `Application` is going away and our process is being terminated — that method is never called in practice.

The Case of the Invisible Activity

Sometimes, you want an activity that has no UI.

This is rather unusual. Mostly, it will be cases where something else in the system says that *it* needs *you* to have an activity, but where you do not really have anything that you want to display to the user in a traditional activity-style UI.

For example, home screen launcher icons only start up activities. However, you may have a need for a home screen launcher that simply triggers some work to be done in the background, perhaps using a service (as will be discussed later in the book).

You have two ways of setting up an invisible activity, both involving using a particular `android:theme` value on the `<activity>` element.

The most efficient option is to use `Theme.Translucent.NoTitleBar`. This sets up your activity to have a transparent background and no action bar. The user may still perceive that the activity is around — for example, it will show up in the overview screen (a.k.a., recent-tasks list). Also, since the activity is "really there", the user may not be able to interact with whatever the user can see, such as the underlying home screen. But, if the activity can `finish()` itself quickly, and is interacting with the

user in the meantime (e.g., displaying some system dialog), you may be able to get away with this approach.

You will also see projects use a `Theme.NoDisplay` theme. This says that there should be no window associated with this particular activity. This too results in an invisible activity.

Occasionally, you need an invisible activity that has to hang around for a few seconds, perhaps waiting on some callback result, before it can be destroyed. Using `Theme.NoDisplay` will still work... but only on older Android devices. On Android 6.0 and higher, using `Theme.NoDisplay` without calling `finish()` in `onCreate()` (or, technically, before `onResume()`) will crash your app. This is why the recommendation is to use `Theme.Translucent.NoTitleBar`, which does not suffer from this limitation.

Tutorial #8 - Setting Up An Activity

Of course, it would be nice if those "Help" and "About" menu choices that we added in the previous tutorial actually did something.

In this tutorial, we will define another activity class, one that will be responsible for displaying simple content like our help text and "about" details. And, we will arrange to start up that activity when those action bar items are selected. The activity will not actually display anything meaningful yet, as that will be the subject of the next few tutorials.

This is a continuation of the work we did in the previous tutorial.

You can find the results of the previous tutorial and the results of this tutorial in the book's GitHub repository.

Step #1: Creating the Stub Activity Class and Manifest Entry

First, we need to define the Java class for our new activity, `SimpleContentActivity`.

Right-click on your `main/` source set directory in the project explorer, and choose New > Activity > Empty Activity from the context menu. This will bring up a new-activity wizard:

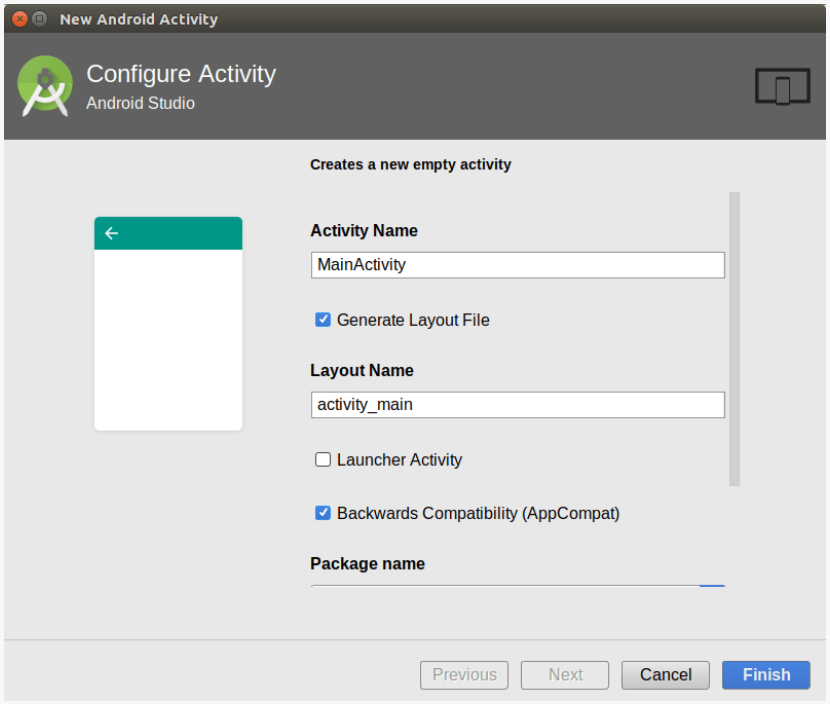

Figure 240: Android Studio New Activity Wizard

Fill in `SimpleContentActivity` in the "Activity Name" field and uncheck the "Generate Layout File" checkbox. Leave "Launcher Activity" unchecked, and uncheck the "Backwards Compatibility (AppCompat)" checkbox. If the package name drop-down is showing the app's package name, leave it alone. On the other hand, if the package name drop-down is empty, click on it and choose the app's package name. Leave the source language drop-down set to Java. Then click on Finish.

At this point, your `SimpleContentActivity` class should look like:

```
package com.commonsware.empublite;

import android.app.Activity;
import android.os.Bundle;

public class SimpleContentActivity extends Activity {

  @Override
  protected void onCreate(Bundle savedInstanceState) {
    super.onCreate(savedInstanceState);
  }
}
```

(from EmPubLite-AndroidStudio/T8-Activities/EmPubLite/app/src/main/java/com/commonsware/empublite/SimpleContentActivity.java)

Step #2: Launching Our Activity

Now that we have declared that the activity exists and can be used, we can start using it.

Go into `EmPubLiteActivity` and modify `onOptionsItemSelected()` to add in some logic in the `R.id.about` and `R.id.help` branches, as shown below:

```
@Override
public boolean onOptionsItemSelected(MenuItem item) {
  switch (item.getItemId()) {
    case R.id.about:
      Intent i=new Intent(this, SimpleContentActivity.class);
      startActivity(i);

      return(true);

    case R.id.help:
      i=new Intent(this, SimpleContentActivity.class);
      startActivity(i);

      return(true);
  }

  return(super.onOptionsItemSelected(item));
}
```

(from EmPubLite-AndroidStudio/T8-Activities/EmPubLite/app/src/main/java/com/commonsware/empublite/EmPubLiteActivity.java)

In those two branches, we create an `Intent`, pointing at our new `SimpleContentActivity`. Then, we call `startActivity()` on that `Intent`. Right now, both `help` and `about` do the same thing — we will add some smarts to have them load up different content later in this book.

You will need to add an import for `android.content.Intent` to get this to compile.

If you run this app in a device or emulator, and you choose either the Help or About menu choices... nothing much appears to happen. In reality, what happens is that our `SimpleContentActivity` appeared, but empty, as we have not given it a full UI yet.

In Our Next Episode…

… we will begin using fragments in our tutorial project.

The Tactics of Fragments

Fragments are an optional layer you can put between your activities and your widgets, designed to help you reconfigure your activities to support screens both large (e.g., tablets) and small (e.g., phones).

This chapter will cover basic uses of fragments.

The Six Questions

In the world of journalism, the basics of any news story consist of six questions, the Five Ws and One H. Here, we will apply those six questions to help frame what we are talking about with respect to fragments.

What?

Fragments are not activities, though they can be used by activities.

Fragments are not containers (i.e., subclasses of `ViewGroup`), though typically they create a `ViewGroup`.

Rather, you should think of fragments as being units of UI reuse. You define a fragment, much like you might define an activity, with layouts and lifecycle methods and so on. However, you can then host that fragment in one or several activities, as needed.

Android does not precisely implement UI architectures like Model-View-Controller (MVC), Model-View-Presenter (MVP), Model-View-ViewModel (MVVM), etc. To the extent that you wish to shove Android into the MVC architecture, fragments and activities combine to be the controller layer. Fragments serve as a local controller,

focused on their set of widgets, populating them from model data, and handling their events. Activities will serve as more of an orchestration layer, handling cross-fragment communications (e.g., a click in Fragment A needs to cause a change in what is displayed in Fragment B).

Functionally, fragments are Java classes, extending from a base `Fragment` class. As we will see, there are two versions of the `Fragment` class, one native to API Level 11 and one supplied by the Android Support package.

Where??

Since fragments are Java classes, your fragments will reside in one of your application's Java packages. The simplest approach is to put them in the same Java package that you used for your project overall and where your activities reside, though you can refactor your UI logic into other packages if needed.

Who?!?

Typically, you create fragment implementations yourself, then tell Android when to use them. Some third-party Android library projects may ship fragment implementations that you can reuse, if you so choose.

When?!!?

Some developers start adding fragments from close to the outset of application development — that is the approach we will take in the tutorials. And, if you are starting a new application from scratch, defining fragments early on is probably a good idea. That being said, it is entirely possible to "retrofit" an existing Android application to use fragments, though this may be a lot of work. And, it is entirely possible to create Android applications without fragments at all.

Fragments were introduced with Android 3.0 (API Level 11, a.k.a., Honeycomb).

WHY?!?!?

Ah, this is the big question. If we have managed to make it this far through the book without fragments, and we do not necessarily need fragments to create Android applications, what is the point? Why would we bother?

The primary rationale for fragments was to make it easier to support multiple screen sizes.

Android started out supporting phones. Phones may vary in size, from tiny ones with less than 3" diagonal screen size (e.g., Sony Ericsson X10 mini), to monsters that are over 5" (e.g., Samsung Galaxy Note). However, those variations in screen size pale in comparison to the differences between phones and tablets, or phones and TVs.

Some applications will simply expand to fill larger screen sizes. Many games will take this approach, simply providing the user with bigger interactive elements, bigger game boards, etc. Any one of the ever-popular Angry Birds game series, when played on an tablet, gives you bigger birds and bigger pigs, not a phone-sized game area surrounded by ad banners.

However, another design approach is to consider a tablet screen to really be a collection of phone screens, side by side.

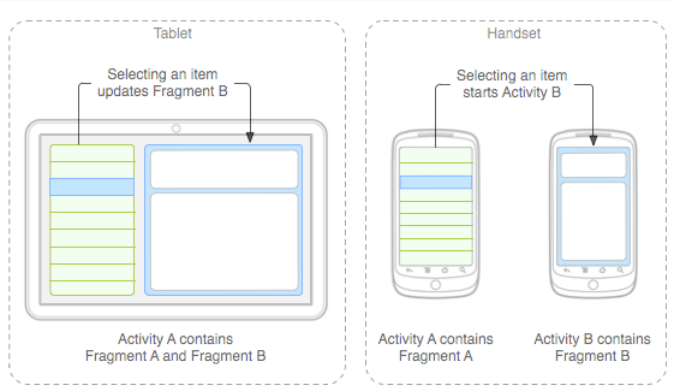

Figure 241: Tablets vs. Handsets (image courtesy of Android Open Source Project)

The user can access all of that functionality at once on a tablet, whereas they would have to flip back and forth between separate screens on a phone.

For applications that can fit this design pattern, fragments allow you to support phones and tablets from one code base. The fragments can be used by individual activities on a phone, or they can be stitched together by a single activity for a tablet.

Details on using fragments to support large screen sizes is a topic for a later chapter in this book. This chapter is focused on the basic mechanics of setting up and using fragments.

OMGOMGOMG, HOW?!?!??

Well, answering that question is what the rest of this chapter is for, plus coverage of more advanced uses of fragments elsewhere in this book.

Where You Get Your Fragments From

Most developers will use the implementation of fragments that has been part of Android since API Level 11. You will use `android.app.Fragment` and have them be hosted by your regular activities.

However, there is a backport of the fragment system available in the Android Support package. This works back to API Level 4, so if your `minSdkVersion` is lower than 11 *and* you want to use fragments, the backport is something that you will wish to consider. You will need to add the `support-v4` JAR to your project (e.g., via `implementation 'com.android.support:support-v4:...'` in your `dependencies` in `build.gradle`, for some value of `...`). You will also need to use `android.support.v4.app.Fragment` instead of `android.app.Fragment`. Also, you will need to host those fragments in an activity inheriting from `android.support.v4.app.FragmentActivity` (as the regular `android.app.Activity` base class does not know about fragments prior to API Level 11).

This book focuses mostly on using the native API Level 11 implementation of fragments, with the occasional example of using the backport where the backport is necessary for one reason or another.

Your First Fragment

In many ways, it is easier to explain fragments by looking at an implementation, more so than trying to discuss them as abstract concepts. So, in this section, we will take a look at the `Fragments/Static` sample project. This is a near-clone of the `Activities/Lifecycle` sample project from the previous chapter. However, we have converted the launcher activity from one that will host widgets directly itself to one that will host a fragment, which in turn manages widgets.

The Fragment Layout

Our fragment is going to manage our UI, so we have a `res/layout/mainfrag.xml` layout file containing our `Button`:

```
<?xml version="1.0" encoding="utf-8"?>
<Button xmlns:android="http://schemas.android.com/apk/res/android"
  android:id="@+id/showOther"
  android:layout_width="match_parent"
  android:layout_height="match_parent"
  android:text="@string/hello"
  android:textSize="20sp"/>
```

(from Fragments/Static/app/src/main/res/layout/mainfrag.xml)

Note, though, that we do not use the `android:onClick` attribute. We will explain why we dropped that attribute from the previous editions of this sample shortly.

The Fragment Class

The project has a `ContentFragment` class that will use this layout and handle the `Button`.

As with activities, there is no constructor on a typical `Fragment` subclass. The primary method you override, though, is not `onCreate()` (though, as we will see later in this chapter, that is possible). Instead, the primary method to override is `onCreateView()`, which is responsible for returning the UI to be displayed for this fragment:

```
  @Override
  public View onCreateView(LayoutInflater inflater,
                           ViewGroup container,
                           Bundle savedInstanceState) {
    View result=inflater.inflate(R.layout.mainfrag, container, false);

    result.findViewById(R.id.showOther).setOnClickListener(this);

    return(result);
  }
```

(from Fragments/Static/app/src/main/java/com/commonsware/android/sfrag/ContentFragment.java)

We are passed a `LayoutInflater` that we can use for inflating a layout file, the `ViewGroup` that will eventually hold anything we inflate, and the `Bundle` that was passed to the activity's `onCreate()` method. While we are used to framework classes loading our layout resources for us, we can "inflate" a layout resource at any time using a `LayoutInflater`. This process reads in the XML, parses it, walks the element tree, creates Java objects for each of the elements, and stitches the results together into a parent-child relationship.

Here, we inflate `res/layout/mainfrag.xml`, telling Android that its contents will eventually go into the `ViewGroup` but not to add it right away. While there are simpler flavors of the `inflate()` method on `LayoutInflater`, this one is required in case the `ViewGroup` happens to be a `RelativeLayout`, so we can process all of the positioning and sizing rules appropriately.

We also use `findViewById()` to find our `Button` widget and tell it that we, the fragment, are its `OnClickListener`. `ContentFragment` must then implement the `View.OnClickListener` interface to make this work. We do this instead of `android:onClick` to route the `Button` click events to the fragment, not the activity.

Since we implement the `View.OnClickListener` interface, we need the corresponding `onClick()` method implementation:

```
@Override
public void onClick(View v) {
  ((StaticFragmentsDemoActivity)getActivity()).showOther(v);
}
```

(from Fragments/Static/app/src/main/java/com/commonsware/android/sfrag/ContentFragment.java)

Any fragment can call `getActivity()` to find the activity that hosts it. In our case, the only activity that will possibly host this fragment is `StaticFragmentsDemoActivity`, so we can cast the result of `getActivity()` to `StaticFragmentsDemoActivity`, so that we can call methods on our activity. In particular, we are telling the activity to show the other activity, by means of calling the `showOther()` method that we saw in the original `Activities/Lifecycle` sample (and will see again shortly).

That is really all that is needed for this fragment. However, `ContentFragment` also overrides many other fragment lifecycle methods, and we will examine these later in this chapter.

The Activity Layout

Originally, the `res/layout/main.xml` used by the activity was where we had our `Button` widget. Now, the `Button` is handled by the fragment. Instead, our activity layout needs to account for the fragment itself.

In this sample, we are going to use a static fragment. Static fragments are easy to add to your application: just use the `<fragment>` element in a layout file, such as our revised `res/layout/main.xml`:

```
<?xml version="1.0" encoding="utf-8"?>
<fragment xmlns:android="http://schemas.android.com/apk/res/android"
  android:layout_width="match_parent"
  android:layout_height="match_parent"
  android:name="com.commonsware.android.sfrag.ContentFragment"/>
```

(from Fragments/Static/app/src/main/res/layout/main.xml)

Here, we are declaring our UI to be completely comprised of one fragment, whose implementation (`com.commonsware.android.sfrag.ContentFragment`) is identified by the `android:name` attribute on the `<fragment>` element. Instead of `android:name`, you can use `class`, though most of the Android documentation has now switched over to `android:name`.

Android Studio users can drag a fragment out of the "Custom" section of the graphical layout editor tool palette, if desired, rather than setting up the `<fragment>` element directly in the XML.

The Activity Class

`StaticFragmentsDemoActivity` — our new launcher activity — looks identical to the previous version, with the exception of the class name:

```
package com.commonsware.android.sfrag;

import android.content.Intent;
import android.os.Bundle;
import android.view.View;

public class StaticFragmentsDemoActivity extends
    LifecycleLoggingActivity {
  @Override
  public void onCreate(Bundle savedInstanceState) {
    super.onCreate(savedInstanceState);
    setContentView(R.layout.main);
  }

  public void showOther(View v) {
    Intent other=new Intent(this, OtherActivity.class);

    other.putExtra(OtherActivity.EXTRA_MESSAGE,
                   getString(R.string.other));
    startActivity(other);
  }
}
```

(from Fragments/Static/app/src/main/java/com/commonsware/android/sfrag/StaticFragmentsDemoActivity.java)

Since the `res/layout/main.xml` file has the `<fragment>` element, the fragment is simply loaded into position in the call to `setContentView()`.

The Fragment Lifecycle Methods

Fragments have lifecycle methods, just like activities do. In fact, they support most of the same lifecycle methods as activities:

- `onCreate()`
- `onStart()` (but not `onRestart()`)
- `onResume()`
- `onPause()`
- `onStop()`
- `onDestroy()`

By and large, the same rules apply for fragments as do for activities with respect to these lifecycle methods (e.g., `onDestroy()` may not be called).

In addition to those and the `onCreateView()` method we examined earlier in this chapter, there are four other lifecycle methods that you can elect to override if you so choose.

`onAttach()` will be called first, even before `onCreate()`, letting you know that your fragment has been attached to an activity. You are passed the `Activity` that will host your fragment.

`onViewCreated()` will be called after `onCreateView()`. This is particularly useful if you are inheriting the `onCreateView()` implementation but need to configure the resulting views, such as with a `ListFragment` and needing to set up an adapter.

`onActivityCreated()` will be called after `onCreate()` and `onCreateView()`, to indicate that the activity's `onCreate()` has completed. If there is something that you need to initialize in your fragment that depends upon the activity's `onCreate()` having completed its work, you can use `onActivityCreated()` for that initialization work.

`onDestroyView()` is called before `onDestroy()`. This is the counterpart to `onCreateView()` where you set up your UI. If there are things that you need to clean up specific to your UI, you might put that logic in `onDestroyView()`.

`onDetach()` is called after `onDestroy()`, to let you know that your fragment has been disassociated from its hosting activity.

onAttach() Versus onAttach()

If you set your project to have a `compileSdkVersion` of 23 or higher, and you attempt to override `onAttach()`, you may get a deprecation warning:

```
@Override
public void onAttach(Activity a) {
  super.onAttach(a);
  Log.d(getClass().getSimpleName(), "onAttach()");
}
```

Figure 242: Android Studio, Showing Deprecated onAttach()

That is because there are *two* versions of `onAttach()` (and `onDetach()`) starting with API Level 23. One takes an `Activity` as a parameter, and the other takes a `Context` as a parameter.

The roles of `onAttach()` and `onDetach()` are the same with either parameter: let you know when the fragment has been attached to or detached from its host. However, now, the host could be anything that extends `Context`, not merely an `Activity`.

On API Level 22 and below, though, only the `Activity` flavor of `onAttach()` and `onDetach()` exists. This leads to a conundrum, as you try to determine exactly how to handle this for your app.

On the whole, if your `minSdkVersion` is below 23, overriding just `onAttach(Activity)` is your best route. It will work on all Android devices that support fragments. Overriding only `onAttach(Context)` will not work, as older devices will ignore it (despite `Activity` being a subclass of `Context`). You could override both methods, but on API Level 23+ devices, both flavors will be called, which may or may not be a good idea for your `Fragment` subclass.

Your First Dynamic Fragment

Static fragments are fairly simple, once you have the `Fragment` implementation: just add the `<fragment>` element to where you want to have the fragment appear in your activity's layout.

That simplicity, though, does come with some costs. We will review some of those limitations in the next chapter.

Those limitations can be overcome by the use of dynamic fragments. Rather than indicating to Android that you wish to use a fragment by means of a `<fragment>` element in a layout, you will use a `FragmentTransaction` to add a fragment at runtime from your Java code.

With that in mind, take a look at the `Fragments/Dynamic` sample project.

This is the same project as the one for static fragments, except this time we will adjust `OtherActivity` to use a dynamic fragment, specifically a `ListFragment`.

The ListFragment Class

`ListFragment` serves the same role for fragments as `ListActivity` does for activities. It wraps up a `ListView` for convenient use. So, to have a more interesting `OtherActivity`, we start with an `OtherFragment` that is a `ListFragment`, designed to show our favorite 25 Latin words as seen in previous examples.

Just as a `ListActivity` does not need to call `setContentView()`, a `ListFragment` does not need to override `onCreateView()`. By default, the entire fragment will be comprised of a single `ListView`. And just as `ListActivity` has a `setListAdapter()` method to associate an `Adapter` with the `ListView`, so too does `ListFragment`:

```
package com.commonsware.android.dfrag;

import android.app.Activity;
import android.app.ListFragment;
import android.os.Bundle;
import android.util.Log;
import android.view.View;
import android.widget.ArrayAdapter;

public class OtherFragment extends ListFragment {
  private static final String[] items= { "lorem", "ipsum", "dolor",
      "sit", "amet", "consectetuer", "adipiscing", "elit", "morbi",
      "vel", "ligula", "vitae", "arcu", "aliquet", "mollis", "etiam",
      "vel", "erat", "placerat", "ante", "porttitor", "sodales",
      "pellentesque", "augue", "purus" };

  @Override
  public void onViewCreated(View view, Bundle savedInstanceState) {
    super.onViewCreated(view, savedInstanceState);
```

```
    setListAdapter(new ArrayAdapter<String>(getActivity(),
                   android.R.layout.simple_list_item_1, items));
  }
```

(from Fragments/Dynamic/app/src/main/java/com/commonsware/android/dfrag/OtherFragment.java)

We call `setListAdapter()` in `onViewCreated()`, as we know that the `ListView` is now ready for use.

This class also overrides many fragment lifecycle methods, logging their results, akin to our other `Fragment` and `LifecycleLoggingActivity`.

The Activity Class

Now, `OtherActivity` no longer needs to load a layout — we have removed `res/layout/other.xml` from the project entirely. Instead, we will use a `FragmentTransaction` to add our fragment to the UI:

```
package com.commonsware.android.dfrag;

import android.os.Bundle;

public class OtherActivity extends LifecycleLoggingActivity {
  @Override
  public void onCreate(Bundle savedInstanceState) {
    super.onCreate(savedInstanceState);

    if (getFragmentManager().findFragmentById(android.R.id.content) == null) {
      getFragmentManager().beginTransaction()
                          .add(android.R.id.content,
                               new OtherFragment()).commit();
    }
  }
}
```

(from Fragments/Dynamic/app/src/main/java/com/commonsware/android/dfrag/OtherActivity.java)

To work with a `FragmentTransaction`, you need the `FragmentManager`. This object knows about all of the fragments that exist in your activity. If you are using the native API Level 11 edition of fragments, you can get your `FragmentManager` by calling `getFragmentManager()`. If you are using the Android Support package, you need to call `getSupportFragmentManager()` instead.

Given a FragmentManager, you can start a FragmentTransaction by calling beginTransaction(), which returns the FragmentTransaction object. FragmentTransaction operates on the builder pattern, so most methods on FragmentTransaction return the FragmentTransaction itself, so you can chain a series of method calls one after the next.

We call two methods on our FragmentTransaction: add() and commit(). The add() method, as you might guess, indicates that we want to add a fragment to the UI. We supply the actual fragment object, in this case by creating a new OtherFragment. We also need to indicate where in our layout we want this fragment to reside. Had we loaded a layout, we could drop this fragment in any desired container. In our case, since we did not load a layout, we supply android.R.id.content as the ID of the container to hold our fragment's View. Here, android.R.id.content identifies the container into which the results of setContentView() would go — it is a container supplied by Activity itself and serves as the top-most container for our content.

Just calling add() is insufficient. We then need to call commit() to make the transaction actually happen.

You might be wondering why we are trying to find a fragment in our FragmentManager before actually creating the fragment. We do that to help deal with configuration changes, and we will be exploring that further in the next chapter.

Fragments and the Action Bar

Fragments can add items to the action bar by calling setHasOptionsMenu(true) from onCreate() (or any other early lifecycle method). This indicates to the activity that it needs to call onCreateOptionsMenu() and onOptionsItemSelected() on the fragment.

The Fragments/ActionBarNative sample application demonstrates this. This has the same functionality as does the ActionBar/ActionBarDemoNative sample from the chapter on the action bar, just with the activity converted into a dynamic fragment.

In onCreate(), we call setHasOptionsMenu(true), to indicate that we are interested in participating in the action bar:

```
@Override
public void onCreate(Bundle savedInstanceState) {
  super.onCreate(savedInstanceState);
```

```
    setRetainInstance(true);
    setHasOptionsMenu(true);
  }
```

(from Fragments/ActionBarNative/app/src/main/java/com/commonsware/android/abf/ActionBarFragment.java)

(we will discuss that `setRetainInstance(true)` call in a later chapter)

That will trigger our fragment's `onCreateOptionsMenu()` and `onOptionsItemSelected()` methods to be called at the appropriate time:

```
  @Override
  public void onCreateOptionsMenu(Menu menu, MenuInflater inflater) {
    inflater.inflate(R.menu.actions, menu);

    super.onCreateOptionsMenu(menu, inflater);
  }

  @Override
  public boolean onOptionsItemSelected(MenuItem item) {
    switch(item.getItemId()) {
      case R.id.add:
        addWord();

        return(true);

      case R.id.reset:
        initAdapter();

        return(true);
    }

    return(super.onOptionsItemSelected(item));
  }
```

(from Fragments/ActionBarNative/app/src/main/java/com/commonsware/android/abf/ActionBarFragment.java)

Here, we initialize our action bar from the `R.menu.actions` menu XML resource, along with the logic to respond to the `add` and `reset` action bar items.

Our activity does not need to do anything special to allow the fragment to contribute to the action bar — it just sets up the dynamic fragment:

```
package com.commonsware.android.abf;

import android.app.Activity;
import android.os.Bundle;
```

```
public class ActionBarFragmentActivity extends Activity {
  @Override
  public void onCreate(Bundle savedInstanceState) {
    super.onCreate(savedInstanceState);

    if (getFragmentManager().findFragmentById(android.R.id.content) == null) {
      getFragmentManager().beginTransaction()
                          .add(android.R.id.content,
                               new ActionBarFragment()).commit();
    }
  }
}
```

(from Fragments/ActionBarNative/app/src/main/java/com/commonsware/android/abf/ActionBarFragmentActivity.java)

Fragments Within Fragments: Just Say "Maybe"

Historically, one major limitation with fragments is that they could not contain other fragments. In most cases, this does not pose a major problem. However, there will be times when you might trip over this limitation, such as when using a `ViewPager`, as will be described in a later chapter.

Android 4.2 — and the Android Support package – added support for nested fragments. Whereas an activity works with fragments via a `FragmentManager` obtained via `getFragmentManager()` or `getSupportFragmentManager()`, fragments can work with nested fragments via a call to `getChildFragmentManager()`.

However, Android 3.0 through 4.1 have a version of fragments that does not have `getChildFragmentManager()`. Hence, you have two options:

1. Use the Android Support package's backport of fragments, until such time as you can drop support for Android 4.1 and earlier, or
2. Do not use nested fragments for the time being.

We will see how `getChildFragmentManager()` works in the chapter on `ViewPager`.

Fragments and Multiple Activities

A fragment should handle functionality purely within the fragment itself. Anything outside the fragment should be the responsibility of the calling activity. For example, if the user taps on an item in a `ListFragment`, and the effects of that event might go

beyond what is inside the `ListFragment` itself, the `ListFragment` should forward the event to the hosting activity, so it can perhaps perform additional steps (e.g., launch an activity, update another fragment hosted by the activity).

As we will see in a later chapter, it is entirely possible — perhaps even likely — that some of our fragments will be hosted by multiple different activities. For example, we might have a fragment that is hosted in one case by an activity designed for larger screens (e.g., tablets) and in another case by an activity designed for smaller screens (e.g., phones).

In these cases, the fragment does not know at compile time which activity class will be hosting it at runtime. For those cases, you have three major options:

1. Have the activities implement a common interface, and have the fragment cast the result of calling `getActivity()` to that interface, so it can call methods on the hosting activity without knowing its exact implementation.
2. Have the activities supply a listener object, with a common interface, to the fragment via a setter, and have the fragment use that listener for raising events and so on.
3. Use an event bus, as we will explore later in this book.

We will see much more on this subject when we get into large-screen strategies in a later chapter.

Tutorial #9 - Starting Our Fragments

Much of the content of a digital book to be viewed in EmPubLite will be in the form of HTML and related assets (CSS, images, etc.). Hence, we will eventually need to render our content in a `WebView` widget, for best results with semi-arbitrary HTML content.

To do this, we will set up fragments for the bits of content:

- each chapter (or, in our case, HTML file containing chapters)
- other material, like our "help" and "about" pages

Right now, we will focus on just setting up some of the basic classes for these fragments — we will load them up with content and display them over the next few tutorials.

This is a continuation of the work we did in the previous tutorial.

You can find the results of the previous tutorial and the results of this tutorial in the book's GitHub repository.

Step #1: Create a SimpleContentFragment

Android has a `WebViewFragment` for the native API Level 11+ implementation of fragments, designed to show some Web content in a `WebView`. In this step, we will create a subclass of `WebViewFragment` that adds in a bit of EmPubLite-specific business logic.

Right-click over the `com.commonsware.empublite` package in your `java/` directory and choose New > "Java Class" from the context menu. That will bring up a new-class dialog:

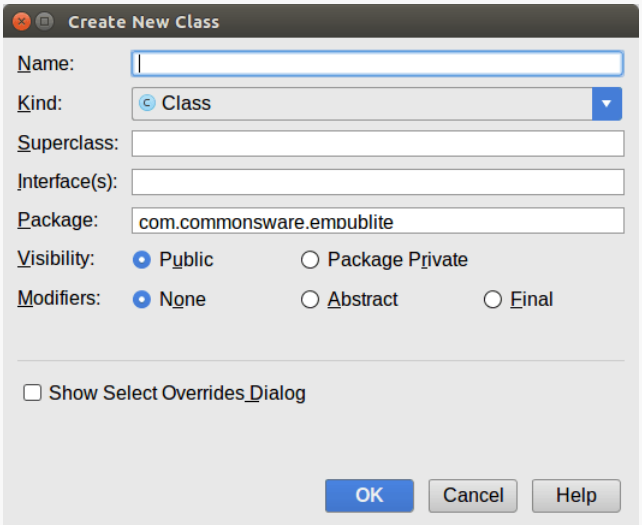

Figure 243: Android Studio New Class Dialog

Fill in `SimpleContentFragment` for the name and `android.app.Fragment` for the superclass. Then, click OK to create this class.

Then, replace the contents of the fragment class with the following code:

```
package com.commonsware.empublite;

import android.annotation.SuppressLint;
import android.os.Bundle;
import android.view.LayoutInflater;
import android.view.View;
import android.view.ViewGroup;
import android.webkit.WebViewFragment;

public class SimpleContentFragment extends WebViewFragment {
  private static final String KEY_FILE="file";

  static SimpleContentFragment newInstance(String file) {
    SimpleContentFragment f=new SimpleContentFragment();

    Bundle args=new Bundle();

    args.putString(KEY_FILE, file);
```

```
    f.setArguments(args);

    return(f);
  }

  @Override
  public void onCreate(Bundle savedInstanceState) {
    super.onCreate(savedInstanceState);
    setRetainInstance(true);
  }

  @SuppressLint("SetJavaScriptEnabled")
  @Override
  public View onCreateView(LayoutInflater inflater,
                           ViewGroup container,
                           Bundle savedInstanceState) {
    View result=
      super.onCreateView(inflater, container, savedInstanceState);

    getWebView().getSettings().setJavaScriptEnabled(true);
    getWebView().getSettings().setSupportZoom(true);
    getWebView().getSettings().setBuiltInZoomControls(true);
    getWebView().loadUrl(getPage());

    return(result);
  }

  private String getPage() {
    return(getArguments().getString(KEY_FILE));
  }
}
```

(from EmPubLite-AndroidStudio/T9-Fragments/EmPubLite/app/src/main/java/com/commonsware/empublite/SimpleContentFragment.java)

If you prefer, you can view this file's contents in your Web browser via this GitHub link.

Step #2: Examining SimpleContentFragment

`SimpleContentFragment` is simple, with a total of four methods:

- `onCreate()`, where we call `setRetainInstance(true)` — the utility of this will be examined in greater detail in an upcoming chapter.
- `onCreateView()`, where we chain to the superclass (to have it create the `WebView`), then configure it to accept JavaScript and support zoom

operations. We then have it load some content, retrieved in the form of a URL from a private `getPage()` method. Finally, we return what the superclass returned from `onCreateView()` — effectively, we are simply splicing in our own configuration logic.

- a `newInstance()` static factory method. This method creates an instance of `SimpleContentFragment`, takes a passed-in `String` (pointing to the file to load), puts it in a `Bundle` identified as `KEY_FILE`, hands the `Bundle` to the fragment as its arguments, and returns the newly-created `SimpleContentFragment`.
- `getPage()`, where it returns a value out of the "arguments" `Bundle` supplied to the fragment — specifically the string identified as `KEY_FILE`.

This means that anyone wanting to use `SimpleContentFragment` should use the factory method, to provide the path to the content to load. We will see why we implemented `SimpleContentFragment` this way in the next chapter.

In Our Next Episode…

… we will set up horizontal swiping of book chapters in our tutorial project.

Swiping with ViewPager

Android, over the years, has put increasing emphasis on UI design and having a fluid and consistent user experience (UX). While some mobile operating systems take "the stick" approach to UX (forcing you to abide by certain patterns or be forbidden to distribute your app), Android takes "the carrot" approach, offering widgets and containers that embody particular patterns that they espouse. The action bar, for example, grew out of this and is now the backbone of many Android activities.

Another example is the `ViewPager`, which allows the user to swipe horizontally to move between different portions of your content. However, `ViewPager` is not distributed as part of the firmware, but rather via the Android Support package. Hence, even though `ViewPager` is a relatively new widget, you can use it on Android 1.6 and up.

This chapter will focus on where you should apply a `ViewPager` and how to set one up.

Pieces of a Pager

`AdapterView` classes, like `ListView`, work with `Adapter` objects, like `ArrayAdapter`. `ViewPager`, however, is not an `AdapterView`, despite adopting many of the patterns from `AdapterView`. `ViewPager`, therefore, does not work with an `Adapter`, but instead with a `PagerAdapter`, which has a slightly different API.

Android ships two `PagerAdapter` implementations in the Android Support package: `FragmentPagerAdapter` and `FragmentStatePagerAdapter`. The former is good for small numbers of fragments, where holding them all in memory at once will work. `FragmentStatePagerAdapter` is for cases where holding all possible fragments to be

viewed in the ViewPager would be too much, where Android will discard fragments as needed and hold onto the (presumably smaller) states of those fragments instead.

Paging Fragments

The simplest way to use a ViewPager is to have it page fragments in and out of the screen based on user swipes.

To see this in action, this section will examine the ViewPager/Fragments sample project.

The project has a dependency on the Android Support package, in order to be able to use ViewPager. In Android Studio, this is a implementation statement in the dependencies closure of build.gradle:

```
dependencies {
  implementation "com.android.support:support-fragment:27.0.2"
  implementation "com.android.support:support-core-ui:27.0.2"
```

(from ViewPager/Fragments/app/build.gradle)

The Activity Layout

The layout used by the activity just contains the ViewPager. Note that since ViewPager is not in the android.widget package, we need to fully-qualify the class name in the element:

```
<?xml version="1.0" encoding="utf-8"?>
<android.support.v4.view.ViewPager xmlns:android="http://schemas.android.com/apk/res/android"
  android:id="@+id/pager"
  android:layout_width="match_parent"
  android:layout_height="match_parent">
</android.support.v4.view.ViewPager>
```

(from ViewPager/Fragments/app/src/main/res/layout/main.xml)

Note that ViewPager is not available for drag-and-drop in the IDE graphical designers, probably because it comes from the Android Support package and therefore is not available to all projects.

The Activity

As you see, the ViewPagerFragmentDemoActivity itself is blissfully small:

```
package com.commonsware.android.pager;

import android.os.Bundle;
import android.support.v4.app.FragmentActivity;
import android.support.v4.view.ViewPager;

public class ViewPagerFragmentDemoActivity extends FragmentActivity {
  @Override
  public void onCreate(Bundle savedInstanceState) {
    super.onCreate(savedInstanceState);
    setContentView(R.layout.main);

    ViewPager pager=findViewById(R.id.pager);

    pager.setAdapter(new SampleAdapter(getSupportFragmentManager()));
  }
}
```

(from ViewPager/Fragments/app/src/main/java/com/commonsware/android/pager/ViewPagerFragmentDemoActivity.java)

All we do is load the layout, retrieve the `ViewPager` via `findViewById()`, and provide a `SampleAdapter` to the `ViewPager` via `setAdapter()`.

The PagerAdapter

Our `SampleAdapter` inherits from `FragmentPagerAdapter` and implements two required callback methods:

- `getCount()`, to indicate how many pages will be in the `ViewPager`, and
- `getItem()`, which returns a `Fragment` for a particular position within the `ViewPager` (akin to `getView()` in a classic `Adapter`)

```
package com.commonsware.android.pager;

import android.support.v4.app.Fragment;
import android.support.v4.app.FragmentManager;
import android.support.v4.app.FragmentPagerAdapter;

public class SampleAdapter extends FragmentPagerAdapter {
  public SampleAdapter(FragmentManager mgr) {
    super(mgr);
  }

  @Override
  public int getCount() {
    return(10);
```

```
  }

  @Override
  public Fragment getItem(int position) {
    return(EditorFragment.newInstance(position));
  }
}
```

(from ViewPager/Fragments/app/src/main/java/com/commonsware/android/pager/SampleAdapter.java)

Here, we say that there will be 10 pages total, each of which will be an instance of an `EditorFragment`. In this case, rather than use the constructor for `EditorFragment`, we are using a `newInstance()` factory method. The rationale for that will be explained in the next section.

The Fragment

`EditorFragment` will host a full-screen `EditText` widget, for the user to enter in a chunk of prose, as is defined in the `res/layout/editor.xml` resource:

```
<EditText xmlns:android="http://schemas.android.com/apk/res/android"
  android:id="@+id/editor"
  android:layout_width="match_parent"
  android:layout_height="match_parent"
  android:inputType="textMultiLine"
  android:gravity="left|top"
  />
```

(from ViewPager/Fragments/app/src/main/res/layout/editor.xml)

We want to pass the position number of the fragment within the `ViewPager`, simply to customize the hint displayed in the `EditText` before the user types in anything. With normal Java objects, you might pass this in via the constructor, but it is not a good idea to implement a constructor on a `Fragment`. Instead, the recipe is to create a static factory method (typically named `newInstance()`) that will create the `Fragment` and provide the parameters to it by updating the fragment's "arguments" (a `Bundle`):

```
  static EditorFragment newInstance(int position) {
    EditorFragment frag=new EditorFragment();
    Bundle args=new Bundle();

    args.putInt(KEY_POSITION, position);
    frag.setArguments(args);
```

```
    return(frag);
  }
```

(from ViewPager/Fragments/app/src/main/java/com/commonsware/android/pager/EditorFragment.java)

You might be wondering why we are bothering with this `Bundle`, instead of just using a regular data member. The arguments `Bundle` is part of our "saved instance state", for dealing with things like screen rotations — a concept we will get into later in the book. For the moment, take it on faith that this is a good idea.

In `onCreateView()` we inflate our `R.layout.editor` resource, get the `EditText` from it, get our position from our arguments, format a hint containing the position (using a string resource), and setting the hint on the `EditText`:

```
@Override
public View onCreateView(LayoutInflater inflater,
                         ViewGroup container,
                         Bundle savedInstanceState) {
  View result=inflater.inflate(R.layout.editor, container, false);
  EditText editor=result.findViewById(R.id.editor);
  int position=getArguments().getInt(KEY_POSITION, -1);

  editor.setHint(String.format(getString(R.string.hint), position + 1));

  return(result);
}
```

(from ViewPager/Fragments/app/src/main/java/com/commonsware/android/pager/EditorFragment.java)

The Result

When initially launched, the application shows the first fragment:

Figure 244: ViewPager on Android 4.3, Showing First Editor

However, you can horizontally swipe to get to the next fragment:

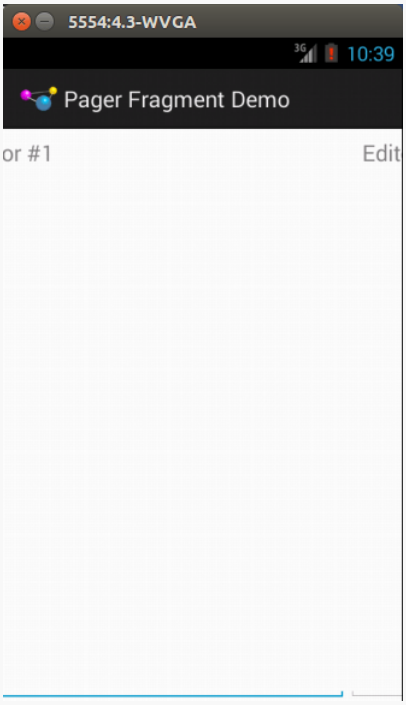

Figure 245: A ViewPager in Use on Android 4.0.3

Swiping works in both directions, so long as there is another page in your desired direction.

Paging Other Stuff

You do not have to use fragments inside a `ViewPager`. A regular `PagerAdapter` actually hands `View` objects to the `ViewPager`. The supplied fragment-based `PagerAdapter` implementations get the `View` from a fragment and use that, but you are welcome to create your own `PagerAdapter` that avoids fragments.

Hence, if you want `ViewPager` to page things other than fragments, the solution is to not use `FragmentPagerAdapter` or `FragmentStatePagerAdapter`, but instead create your own implementation of the `PagerAdapter` interface, one that avoids the use of fragments.

We will see an example of this in a later chapter, where we also examine how to have more than one page of the `ViewPager` be visible at a time.

Indicators

By itself, there is no visual indicator of where the user is within the set of pages contained in the `ViewPager`. In many instances, this will be perfectly fine, as the pages themselves will contain cues as to position. However, even in those cases, it may not be completely obvious to the user how many pages there are, which directions for swiping are active, etc.

Hence, you may wish to attach some other widget to the `ViewPager` that can help clue the user into where they are within "page space".

PagerTitleStrip and PagerTabStrip

The primary built-in indicator options available to use are `PagerTitleStrip` and `PagerTabStrip`. As the name suggests, `PagerTitleStrip` is a strip that shows titles of your pages. `PagerTabStrip` is much the same, but the titles are formatted somewhat like tabs, and they are clickable (switching you to the clicked-upon page), whereas `PagerTitleStrip` is non-interactive.

To use either of these, you first must add it to your layout, inside your `ViewPager`, as shown in the `res/layout/main.xml` resource of the `ViewPager/Indicator` sample project, a clone of the `ViewPager/Fragments` project that adds a `PagerTabStrip` to our UI:

```
<?xml version="1.0" encoding="utf-8"?>
<android.support.v4.view.ViewPager xmlns:android="http://schemas.android.com/apk/res/android"
  android:id="@+id/pager"
  android:layout_width="match_parent"
  android:layout_height="match_parent">

  <android.support.v4.view.PagerTabStrip
    android:layout_width="match_parent"
    android:layout_height="wrap_content"
    android:layout_gravity="top"/>

</android.support.v4.view.ViewPager>
```

(from ViewPager/Indicator/app/src/main/res/layout/main.xml)

Here, we set the `android:layout_gravity` of the `PagerTabStrip` to `top`, so it appears above the pages. You could similarly set it to `bottom` to have it appear below the pages.

Our `SampleAdapter` needs another method: `getPageTitle()`, which will return the title to display in the `PagerTabStrip` for a given position:

```
package com.commonsware.android.pager2;

import android.app.Fragment;
import android.app.FragmentManager;
import android.content.Context;
import android.support.v13.app.FragmentPagerAdapter;

public class SampleAdapter extends FragmentPagerAdapter {
  Context ctxt=null;

  public SampleAdapter(Context ctxt, FragmentManager mgr) {
    super(mgr);
    this.ctxt=ctxt;
  }

  @Override
  public int getCount() {
    return(10);
  }

  @Override
  public Fragment getItem(int position) {
    return(EditorFragment.newInstance(position));
  }

  @Override
  public String getPageTitle(int position) {
    return(EditorFragment.getTitle(ctxt, position));
  }
}
```

(from ViewPager/Indicator/app/src/main/java/com/commonsware/android/pager2/SampleAdapter.java)

Here, we call a static `getTitle()` method on `EditorFragment`. That is a refactored bit of code from our former `onCreateView()` method, where we create the string for the hint — we will use the hint text as our page title:

```
package com.commonsware.android.pager2;

import android.app.Fragment;
import android.content.Context;
import android.os.Bundle;
import android.view.LayoutInflater;
import android.view.View;
import android.view.ViewGroup;
import android.widget.EditText;
```

```
public class EditorFragment extends Fragment {
  private static final String KEY_POSITION="position";

  static EditorFragment newInstance(int position) {
    EditorFragment frag=new EditorFragment();
    Bundle args=new Bundle();

    args.putInt(KEY_POSITION, position);
    frag.setArguments(args);

    return(frag);
  }

  static String getTitle(Context ctxt, int position) {
    return(String.format(ctxt.getString(R.string.hint), position + 1));
  }

  @Override
  public View onCreateView(LayoutInflater inflater,
                           ViewGroup container,
                           Bundle savedInstanceState) {
    View result=inflater.inflate(R.layout.editor, container, false);
    EditText editor=(EditText)result.findViewById(R.id.editor);
    int position=getArguments().getInt(KEY_POSITION, -1);

    editor.setHint(getTitle(getActivity(), position));

    return(result);
  }
}
```

(from ViewPager/Indicator/app/src/main/java/com/commonsware/android/pager2/EditorFragment.java)

Figure 246: ViewPager and PagerTabStrip on Android 4.3, Showing Second Page

Other Indicator Options

There are many other options for tab-style indicators with a `ViewPager`.

`TabLayout` is the only other one officially supported by Google. It comes from the Design Support library, which in turn requires `appcompat-v7`.

Most of the options are open source libraries. The chapter on the Design Support library demonstrates one such third-party library, The Android Arsenal's roster of `ViewPager` add-ons mostly consists of indicators, both those formatted like tabs and those that use other approaches.

Revisiting the Containers Sampler

Earlier in the book, we looked at many different layout resources from the `Containers/Sampler` sample project. These were to illustrate how different layout structures work. The whole UI is wrapped up in a `ViewPager` with a `PagerTabStrip`. However, we set up the `FragmentPagerAdapter` and the fragments based on a roster of available sample layouts, driven by resources.

The Layout

The layout that is used for the `ViewPager` and `PagerTabStrip` is largely the same as what we saw earlier in this chapter:

```
<?xml version="1.0" encoding="utf-8"?>
<android.support.v4.view.ViewPager xmlns:android="http://schemas.android.com/apk/res/android"
  android:id="@+id/pager"
  android:layout_width="match_parent"
  android:layout_height="match_parent">

  <android.support.v4.view.PagerTabStrip
    android:layout_width="match_parent"
    android:layout_height="wrap_content"
    android:layout_gravity="top"/>

</android.support.v4.view.ViewPager>
```

(from Containers/Sampler/app/src/main/res/layout/main.xml)

So, we have a `ViewPager` named `pager`, with a `PagerTabStrip` anchored at the top via `android:layout_gravity="top"`.

The Data

The data about what layouts to show as tabs is contained in a pair of array resources. Array resources, as the name suggests, are resources that hold onto a collection of items. The convention is that they go in `res/values/arrays.xml`, though the actual filename is not required to be `arrays.xml`.

The sample app has a `res/values/arrays.xml` file, containing two array resources: a `<string-array>` named `titles` and a generic `<array>` named `layouts`:

```
<?xml version="1.0" encoding="utf-8"?>
<resources>
  <string-array name="titles">
    <item>No Container</item>
    <item>Bottom-then-Top: LinearLayout</item>
    <item>Bottom-then-Top: RelativeLayout</item>
    <item>Bottom-then-Top: ConstraintLayout</item>
    <item>Stacked Percent: LinearLayout</item>
    <item>Stacked Percent: ConstraintLayout</item>
    <item>URL Dialog: LinearLayout</item>
    <item>URL Dialog: RelativeLayout</item>
    <item>URL Dialog: TableLayout</item>
    <item>URL Dialog: ConstraintLayout</item>
    <item>Form: TableLayout</item>
```

```
    <item>Form: LinearLayout</item>
    <item>Overlap: RelativeLayout</item>
    <item>Center: RelativeLayout</item>
    <item>Center: ConstraintLayout</item>
    <item>Bias: ConstraintLayout</item>
    <item>Bias: LinearLayout</item>
    <item>Bias: ConstraintLayout Peers</item>
    <item>Aspect: ConstraintLayout</item>
    <item>Center Align: LinearLayout</item>
    <item>Center Align: ConstraintLayout</item>
    <item>Chains: ConstraintLayout</item>
  </string-array>
  <array name="layouts">
    <item>@layout/no_container</item>
    <item>@layout/bottom_then_top_ll</item>
    <item>@layout/bottom_then_top_rl</item>
    <item>@layout/bottom_then_top_cl</item>
    <item>@layout/stacked_percent_ll</item>
    <item>@layout/stacked_percent_cl</item>
    <item>@layout/url_dialog_ll</item>
    <item>@layout/url_dialog_rl</item>
    <item>@layout/url_dialog_tl</item>
    <item>@layout/url_dialog_cl</item>
    <item>@layout/form_tl</item>
    <item>@layout/form_ll</item>
    <item>@layout/overlap_rl</item>
    <item>@layout/center_rl</item>
    <item>@layout/center_cl</item>
    <item>@layout/bias_cl</item>
    <item>@layout/bias_ll</item>
    <item>@layout/bias_peers_cl</item>
    <item>@layout/aspect_cl</item>
    <item>@layout/center_align_ll</item>
    <item>@layout/center_align_cl</item>
    <item>@layout/chains_cl</item>
  </array>
</resources>
```

(from Containers/Sampler/app/src/main/res/values/arrays.xml)

As the name suggests, a `<string-array>` holds strings. Here, it holds literal strings. Alternatively, those could be references to string resources, using the same `@string/...` naming convention that we have seen elsewhere in the book.

The `layouts` array holds references to the corresponding layout resources, using `@layout/...` syntax to identify those resources.

These two arrays are set up in the same order, so the first title is used for the first layout, the second title is used for the second layout, and so on.

The Fragment

The fragment for the pages in the `ViewPager` is a `static` nested class within the `MainActivity`, named `LayoutFragment`. This is atypical; usually a fragment will be in its own Java class. That is because usually a fragment has a lot of code associated with it. In this case, `LayoutFragment` is rather short:

```
public static class LayoutFragment extends Fragment {
  private static final String ARG_LAYOUT="layout";

  static LayoutFragment newInstance(int layoutId) {
    LayoutFragment result=new LayoutFragment();
    Bundle args=new Bundle();

    args.putInt(ARG_LAYOUT, layoutId);
    result.setArguments(args);

    return(result);
  }

  @Override
  public View onCreateView(LayoutInflater inflater,
                           ViewGroup container,
                           Bundle savedInstanceState) {
    return(inflater.inflate(getArguments().getInt(ARG_LAYOUT),
      container, false));
  }
}
```

(from Containers/Sampler/app/src/main/java/com/commonsware/android/containers/sampler/MainActivity.java)

When we create an instance of `LayoutFragment` through the `newInstance()` factory method, we pass in a layout resource ID. Through the arguments `Bundle`, that becomes available to our `onCreateView()` method, which simply inflates that layout and returns it.

The fragment is so short because we are not doing anything with the widgets inside of the inflated layout, such as filling them with data or setting up event listeners.

The Activity

The `MainActivity` that contains `LayoutFragment` has only one method of its own: `onCreate()`, which inflates the `res/layout/main.xml` resource shown above, finds the `ViewPager`, and sets its adapter to be a `SampleAdapter`:

```
@Override
public void onCreate(Bundle savedInstanceState) {
  super.onCreate(savedInstanceState);
  setContentView(R.layout.main);

  ViewPager pager=(ViewPager)findViewById(R.id.pager);

  pager.setAdapter(new SampleAdapter(getFragmentManager()));
}
```

(from Containers/Sampler/app/src/main/java/com/commonsware/android/containers/sampler/MainActivity.java)

In other words, this `onCreate()` is pretty much the same as the others seen in this chapter. Where the fun lies is in this sample app's edition of `SampleAdapter`.

The PagerAdapter

`SampleAdapter` uses the contents of those two array resources to determine how many pages there are, what to show in the tabs, and what layout resource ID to pass to the `LayoutFragment`:

```
private class SampleAdapter extends FragmentPagerAdapter {
  private int[] layouts;
  private String[] titles;

  SampleAdapter(FragmentManager mgr) {
    super(mgr);
    layouts=getLayoutsArray(R.array.layouts);
    titles=getResources().getStringArray(R.array.titles);
  }

  @Override
  public int getCount() {
    return(titles.length);
  }

  @Override
  public Fragment getItem(int position) {
    return(LayoutFragment.newInstance(layouts[position]));
```

```
  }

  @Override
  public CharSequence getPageTitle(int position) {
    return(titles[position]);
  }

  int[] getLayoutsArray(int arrayResourceId) {
    TypedArray typedArray=
      getResources().obtainTypedArray(arrayResourceId);
    int[] result=new int[typedArray.length()];

    for (int i=0;i<typedArray.length();i++) {
      result[i]=typedArray.getResourceId(i, -1);
    }

    return(result);
  }
}
```

(from Containers/Sampler/app/src/main/java/com/commonsware/android/containers/sampler/MainActivity.java)

`SampleAdapter` holds onto a `String` array of the titles. This is populated by `getResources().getStringArray()` in the `SampleAdapter` constructor, which reads in the `titles` `<string-array>` resource. Those strings are then used for the `getPageTitle()` method, and the length of the `strings` array is used for `getCount()`.

Getting the equivalent array of the `int` values for the layout resource IDs is more cumbersome. We could try calling `getIntArray()` on the `Resources` object returned by `getResources()`. However, that only works for `<int-array>` resources. We cannot use one of those in `res/values/arrays.xml` because Android considers `@layout/...` to be a resource ID, not just a simple integer.

To work with a generic `<array>` resource, we need to call `obtainTypedArray()` on the `Resources` object, which we do in the `getLayoutsArray()` helper method. This returns a `TypedArray`, which effectively is an array of arbitrary resource types. We know that our array should be all layout resource IDs, so we allocate an `int` array to be our result (based upon the `length()` of the `TypedArray`), then iterate over all of the entries and retrieve the resource ID for that array position (using `getResourceId()`). In the end, `result` has an array of resource IDs, and those get used by `getItem()` to supply `LayoutFragment` with the appropriate layout resource ID for this page's position.

There is a chapter on advanced `ViewPager` techniques that may interest you!

Tutorial #10 - Rigging Up a ViewPager

A `ViewPager` is a fairly slick way to present a digital book. You can have individual portions of the book be accessed by horizontal swiping, with the prose within a portion accessed by scrolling vertically. While not offering "page-at-a-time" models used by some book reader software, it is **much** simpler to set up.

So, that's the approach we will use with EmPubLite. Which means, among other things, that we need to add a `ViewPager` to the app.

This is a continuation of the work we did in the previous tutorial.

You can find the results of the previous tutorial and the results of this tutorial in the book's GitHub repository.

Step #1: Add a ViewPager to the Layout

Right now, the `main` layout used by `EmPubLiteActivity` just has a `TextView`. We need to change that to have our `ViewPager`.

Since `ViewPager` is not available for drag-and-drop through the IDE graphical layout editors, even IDE users are going to have to dive into the layout XML this time.

Open up `res/layout/main.xml` and switch to the Text sub-tab to see the raw XML. Replace its contents with:

```
<?xml version="1.0" encoding="utf-8"?>
<LinearLayout xmlns:android="http://schemas.android.com/apk/res/android"
  xmlns:app="http://schemas.android.com/apk/res-auto"
  android:layout_width="match_parent"
  android:layout_height="match_parent"
```

```
  android:orientation="vertical">

  <io.karim.MaterialTabs
    android:id="@+id/tabs"
    android:layout_width="match_parent"
    android:layout_height="48dp"
    app:mtIndicatorColor="@color/colorAccent"
    app:mtSameWeightTabs="true"/>

  <android.support.v4.view.ViewPager
    android:id="@+id/pager"
    android:layout_width="match_parent"
    android:layout_height="match_parent">
  </android.support.v4.view.ViewPager>
</LinearLayout>
```

(from EmPubLite-AndroidStudio/T10-ViewPager/EmPubLite/app/src/main/res/layout/main.xml)

This adds our `ViewPager`, underneath a `MaterialTabs`, inside a `vertical` `LinearLayout`. `MaterialTabs` is an implementation of tabs for a `ViewPager`, one that we will explore in greater detail later in the book.

Step #2: Creating a ContentsAdapter

A `ViewPager` needs a `PagerAdapter` to populate its content, much like a `ListView` needs a `ListAdapter`. We cannot completely construct a `PagerAdapter` yet, as we still need to learn how to load up our book content from files. But, we can get part-way towards having a useful `PagerAdapter` now.

Right-click over the `com.commonsware.empublite` package in your `java/` directory and choose New > Java Class from the context menu. Fill in `ContentsAdapter` as the name and click OK to create the empty class.

Then, replace the generated `ContentsAdapter.java` file with the following content:

```
package com.commonsware.empublite;

import android.app.Activity;
import android.app.Fragment;
import android.support.v13.app.FragmentStatePagerAdapter;

public class ContentsAdapter extends FragmentStatePagerAdapter {
  public ContentsAdapter(Activity ctxt) {
    super(ctxt.getFragmentManager());
  }
```

```
  @Override
  public Fragment getItem(int arg0) {
// TODO Auto-generated method stub
    return null;
  }

  @Override
  public int getCount() {
// TODO Auto-generated method stub
    return 0;
  }
}
```

(from EmPubLite-AndroidStudio/T10-ViewPager/EmPubLite/app/src/main/java/com/commonsware/empublite/ContentsAdapter.java)

If you prefer, you can view this file's contents in your Web browser via this GitHub link.

Step #3: Setting Up the ViewPager

Now, we need to add some code to retrieve the `ViewPager`, populate it with the `ContentsAdapter`, and do something useful with those tabs.

First, add two fields to `EmPubLiteActivity`:

```
  private ViewPager pager;
  private ContentsAdapter adapter;
```

(from EmPubLite-AndroidStudio/T10-ViewPager/EmPubLite/app/src/main/java/com/commonsware/empublite/EmPubLiteActivity.java)

This will require adding an `import` for `android.support.v4.view.ViewPager`.

Then, add a few more lines to the bottom of `onCreate()` of `EmPubLiteActivity`:

```
    pager=(ViewPager)findViewById(R.id.pager);
    adapter=new ContentsAdapter(this);
    pager.setAdapter(adapter);

    MaterialTabs tabs=(MaterialTabs)findViewById(R.id.tabs);
    tabs.setViewPager(pager);
```

(from EmPubLite-AndroidStudio/T10-ViewPager/EmPubLite/app/src/main/java/com/commonsware/empublite/EmPubLiteActivity.java)

This will require an `import` statement for `io.karim.MaterialTabs`.

What we are doing is:

- Retrieving our `ViewPager`, holding onto it in its field,
- Creating an instance of the do-nothing `ContentsAdapter`,
- Associating the `ContentsAdapter` with the `ViewPager`,
- Retrieving the `MaterialTabs`, and
- Attaching the tabs to the `ViewPager`

At this point, your `EmPubLiteActivity` should look something like:

```
package com.commonsware.empublite;

import android.app.Activity;
import android.content.Intent;
import android.os.Bundle;
import android.support.v4.view.ViewPager;
import android.view.Menu;
import android.view.MenuItem;
import io.karim.MaterialTabs;

public class EmPubLiteActivity extends Activity {
  private ViewPager pager;
  private ContentsAdapter adapter;

  @Override
  protected void onCreate(Bundle savedInstanceState) {
    super.onCreate(savedInstanceState);
    setContentView(R.layout.main);

    pager=(ViewPager)findViewById(R.id.pager);
    adapter=new ContentsAdapter(this);
    pager.setAdapter(adapter);

    MaterialTabs tabs=(MaterialTabs)findViewById(R.id.tabs);
    tabs.setViewPager(pager);
  }

  @Override
  public boolean onCreateOptionsMenu(Menu menu) {
    getMenuInflater().inflate(R.menu.options, menu);

    return(super.onCreateOptionsMenu(menu));
  }
```

```
  @Override
  public boolean onOptionsItemSelected(MenuItem item) {
    switch (item.getItemId()) {
      case R.id.about:
        Intent i=new Intent(this, SimpleContentActivity.class);
        startActivity(i);

        return(true);

      case R.id.help:
        i=new Intent(this, SimpleContentActivity.class);
        startActivity(i);

        return(true);
    }

    return(super.onOptionsItemSelected(item));
  }
}
```

(from EmPubLite-AndroidStudio/T10-ViewPager/EmPubLite/app/src/main/java/com/commonsware/empublite/EmPubLiteActivity.java)

The net effect, if you run this modified version of the app, is that we have a big blank area, taken up by our empty `ViewPager`:

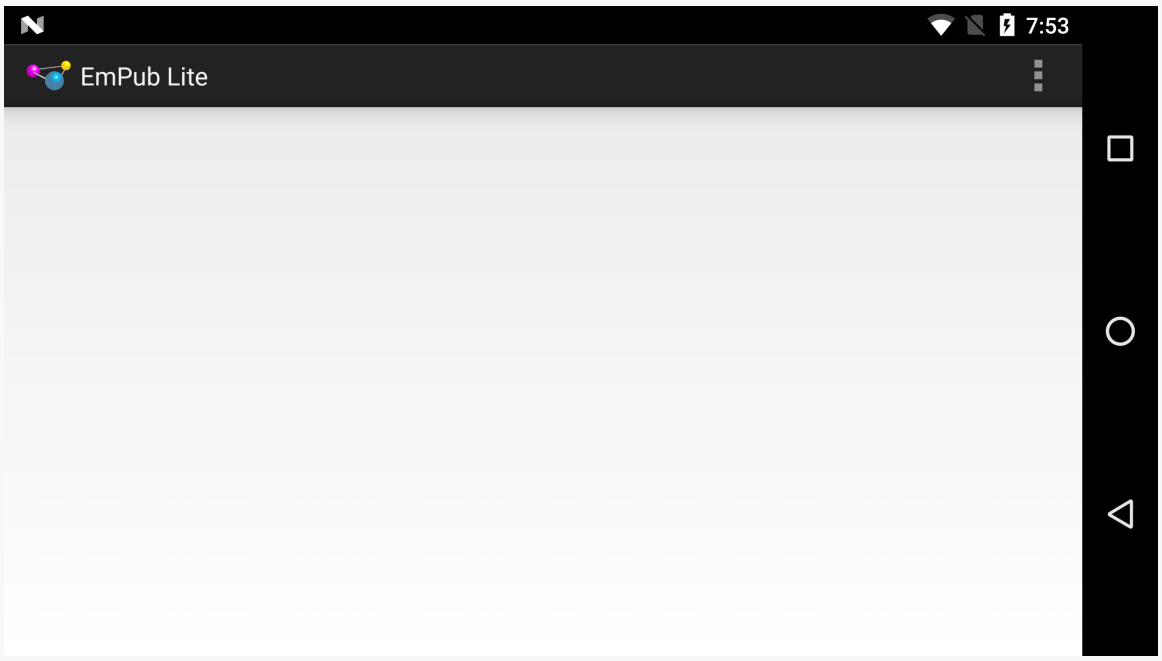

Figure 247: EmPubLite, With Empty ViewPager

The `ViewPager` is empty simply because our `ContentsAdapter` returned `0` from `getCount()`, indicating that there are no pages to be displayed.

In Our Next Episode…

… we will finish our "help" and "about" screens in our tutorial project.

Resource Sets and Configurations

Devices sometimes change while users are using them, in ways that our application will care about:

- The user might rotate the screen from portrait to landscape, or vice versa
- The user might put the device in a car or desk dock, or remove it from such a dock
- The user might put the device in a "netbook dock" that adds a full QWERTY keyboard, or remove it from such a dock
- The user might switch to a different language via the Settings application, returning to our running application afterwards
- And so on

In all of these cases, it is likely that we will want to change what resources we use. For example, our layout for a portrait screen may be too tall to use in landscape mode, so we would want to substitute in some other layout.

This chapter will explore how to provide alternative resources for these different scenarios — called "configuration changes" — and will explain what happens to our activities when the user changes the configuration while we are in the foreground.

What's a Configuration? And How Do They Change?

Different pieces of Android hardware can have different capabilities, such as:

- Different screen sizes
- Different screen densities (dots per inch)

- Different number and capabilities of cameras
- Different mix of radios (GSM? CDMA? GPS? Bluetooth? WiFi? NFC? something else?)
- And so on

Some of these, in the eyes of the core Android team, might drive the selection of resources, like layouts or drawables. Different screen sizes might drive the choice of layout. Different screen densities might drive the choice of drawable (using a higher-resolution image on a higher-density device). These are considered part of the device's "configuration".

Other differences — ones that do not drive the selection of resources — are not part of the device's configuration but merely are "features" that some devices have and other devices do not. For example, cameras and Bluetooth and WiFi are features.

Some parts of a configuration will only vary based on different devices. A screen will not change density on the fly, for example. But some parts of a configuration can be changed during operation of the device, such as orientation (portrait vs. landscape) or language. When a configuration switches to something else, that is a "configuration change", and Android provides special support for such events to help developers adjust their applications to match the new configuration.

Configurations and Resource Sets

One set of resources may not fit all situations where your application may be used. One obvious area comes with string resources and dealing with internationalization (I18N) and localization (L10N). Putting strings all in one language works fine — probably at least for the developer — but only covers one language.

That is not the only scenario where resources might need to differ, though. Here are others:

1. *Screen orientation*: is the screen in a portrait orientation? Landscape?
2. *Screen size*: is this something sized like a phone? A tablet? A television?
3. *Screen density*: how many dots per inch does the screen have? Will we need a higher-resolution edition of our icon so it does not appear too small?
4. *Keyboard*: what keyboard does the user have (QWERTY, numeric, neither), either now or as an option?
5. *Other input*: does the device have some other form of input, like a directional pad or click-wheel?

The way Android currently handles this is by having multiple resource directories, with the criteria for each embedded in their names.

Suppose, for example, you want to support strings in both English and Spanish. Normally, for a single-language setup, you would put your strings in a file named `res/values/strings.xml`. To support both English and Spanish, you could create two folders, `res/values-en/` and `res/values-es/`, where the value after the hyphen is the ISO 639-1 two-letter code for the language you want. Your English-language strings would go in `res/values-en/strings.xml` and the Spanish ones in `res/values-es/strings.xml`. Android will choose the proper file based on the user's device settings. Note that Android 5.0 added support for BCP 47 three-letter language and locale values.

However, the **better** approach is for you to consider some language to be your default, and put those strings in `res/values/strings.xml`. Then, create other resource directories for your translations (e.g., `res/values-es/strings.xml` for Spanish). Android will try to match a specific language set of resources; failing that, it will fall back to the default of `res/values/strings.xml`. This way, if your app winds up on a device with a language that you do not expect, you at least serve up strings in your chosen default language. Otherwise, if there is no such default, you will wind up with a `ResourceNotFoundException`, and your application will crash.

This, therefore, is the bedrock resource set strategy: have a complete set of resources in the default directory (e.g., `res/layout/`), and override those resources in other resource sets tied to specific configurations as needed (e.g., `res/layout-land/`).

Note that Android Studio has a translations editor to help you manage your string resources for your default language and whatever translations you are going to include in your app.

Screen Size and Orientation

Perhaps the most important resource set qualifiers that we have not yet seen are the ones related to screen size and orientation. Here, "orientation" refers to how the device is being held: portrait or landscape.

Orientation is fairly easy, as you can just use `-port` or `-land` as resource set qualifiers to restrict resources in a directory to a specific orientation. The convention is to put landscape resources in a `-land` directory (e.g., `res/layout-land/`) and to put

portrait resource in the default directory (e.g., `res/layout/`). However, this is merely a convention, and you are welcome to use `-port` if you prefer.

Screen size is a bit more complicated, simply because the available approaches have changed over the years.

The Original: Android-Defined Buckets

Way back in the beginning, with Android 1.0, all screen sizes were created equal... mostly because there was only one screen size, and that mostly because there was only one device.

Android 1.5, however, introduced three screen sizes and associated resource set qualifiers, with a fourth (`-xlarge`) added later:

- `-small` for screens at or under 3" in diagonal size
- `-normal` for screens between 3" and 5" in diagonal size
- `-large` for screens between 5" and 10" in diagonal size
- `-xlarge` for screens at or over 10" in diagonal size

As we will see, these resource set qualifiers establish lower bounds for when a directory's worth of resources will be used. So a `res/layout-normal/` directory will not be used for `-small` screens but would be used for `-normal`, `-large`, and `-xlarge` screens.

The Modern: Developer-Defined Buckets

The problem with the classic size buckets is that they were fairly inflexible. What if you think that so-called "phablets", like the Samsung Galaxy Note series, should have layouts more like phones, while larger tablets, such as the 8.9" Kindle Fire HD, should have layouts more like 10" tablets? That was not possible given the fixed buckets.

Android 3.2 gave us more control. We can have our own buckets for screen size, using the somewhat-confusing `-swNNNdp` resource set qualifier. Here, the `NNN` is replaced by you with a value, measured in `dp`, for the *smallest width* of the screen. "Smallest width" basically means the width of the screen when the device is held in portrait mode. Hence, rather than measuring based on diagonal screen size, as with the classic buckets, your custom buckets are based on the linear screen size of the shortest screen side.

For example, suppose that you wish to consider a dividing line between resources to be at the 7" point — 7" and smaller devices would get one set of layouts, while larger devices would get a different set of layouts. 7" tablets usually have a smallest width of around 3.5" to 3.75", given common aspect ratios. Since 1 `dp` is 1/160th of an inch, those smallest widths equate to 560-600 `dp`. Hence, you might set up a `-sw600dp` resource set for your larger layouts, and put the smaller layouts in a default resource set.

Mashups: Width and Height Buckets

Using `-swNNNdp` does not address orientation, as the smallest width is the same regardless of whether the device is held in portrait or landscape. Hence, you would need to add `-swNNNdp-land` as a resource set for landscape resources for your chosen dividing line.

An alternative is to use `-wNNNdp` or `-hNNNdp`. These resource set qualifiers work much like `-swNNNdp`, particularly in terms of what `NNN` means. However, whereas `-swNNNdp` refers to the smallest width, `-wNNNdp` refers the *current* width, and `-hNNNdp` refers to the *current* height. Hence, these change with orientation changes.

About That API Level

`-swNNNdp`, `-wNNNdp`, and `-hNNNdp` were added in API Level 13. Hence, older devices will ignore any resource sets with those qualifiers.

In principle, this might seem like a big problem, for those developers still supporting older devices.

In practice, it is less of an issue than you might expect, simply because the *vast* majority of those older devices were phones, not tablets. The only Android 2.x tablets that sold in any significant quantity were three 7" models:

- the original Kindle Fire
- the original Barnes & Noble NOOK series
- the original Samsung Galaxy Tab

Of those, only the Galaxy Tab had the then-Android Market (now the Play Store). Hence, if you are only distributing via the Play Store, you might be in position to simply ignore pre-API Level 13 tablets. Use `-swNNNdp` to create your dividing line for larger devices, and the Galaxy Tab will simply use the layouts for your smaller devices.

If this concerns you, or you are also supporting the Kindle Fire and early NOOKs, you can use layout aliases to minimize code duplication. For example, suppose that you have a `res/layout/main.xml` that you wanted to have different versions for phones and tablets, and you want to use `-swNNNdp` for your dividing line as to where the tablet layouts get used, but you also want to have the older tablets, like the Galaxy Tab, use the following recipe:

- Put your tablet-sized layouts in `res/layout/`, but with *different* filenames (e.g., `res/layout/main_to_be_used_for_tablets.xml`)
- In `res/values-swNNNdp/layouts.xml`, for your chosen value of `NNN`, put aliases (via `<item>` elements) for the original names (via the `name` attribute) pointing to the resources you want to use for `-swNNNdp` devices:

```
<resources>
    <item name="main" type="layout">@layout/main_to_be_used_for_tablets</item>
</resources>
```

- In `res/values-large/layouts.xml`, put those same aliases

Now, both older and newer devices, when referencing the same resource name, will get routed to the right layouts for their screen size.

Coping with Complexity

Where things start to get complicated is when you need to use multiple disparate criteria for your resources.

For example, suppose that you have drawable resources that are locale-dependent, such as a stop sign. You might want to have resource sets of drawables tied to language, so you can substitute in different images for different locales. However, you might also want to have those images vary by density, using higher-resolution images on higher-density devices, so the images all come out around the same physical size.

To do that, you would wind up with directories with multiple resource set qualifiers, such as:

- `res/drawable-ldpi/`
- `res/drawable-mdpi/`
- `res/drawable-hdpi/`
- `res/drawable-xhdpi/`

- `res/drawable-en-rUK-ldpi/`
- `res/drawable-en-rUK-mdpi/`
- `res/drawable-en-rUK-hdpi/`
- `res/drawable-en-rUK-xhdpi/`
- And so on

(with the default language being, say, US English, using a US stop sign)

Once you get into these sorts of situations, though, a few rules come into play, such as:

1. The configuration options (e.g., `-en`) have a particular order of precedence, and they must appear in the directory name in that order. The Android documentation outlines the specific order in which these options can appear. For the purposes of this example, screen size is more important than screen orientation, which is more important than screen density, which is more important than whether or not the device has a keyboard.
2. There can only be one value of each configuration option category per directory.
3. Options are case sensitive

For example, you might want to have different layouts based upon screen size and orientation. Since screen size is more important than orientation in the resource system, the screen size would appear in the directory name ahead of the orientation, such as:

- `res/layout-sw600dp-land/`
- `res/layout-sw600dp/`
- `res/layout-land/`
- `res/layout/`

Choosing The Right Resource

Given that you can have N different definitions of a resource, how does Android choose the one to use?

First, Android tosses out ones that are specifically invalid. So, for example, if the language of the device is `-ru`, Android will ignore resource sets that specify other languages (e.g., `-zh`). The exceptions to this are density qualifiers and screen size qualifiers — we will get to those exceptions later.

Then, Android chooses the resource set that has the desired resource and has *the most important distinct qualifier*. Here, by "most important", we mean the one that appears left-most in the directory name, based upon the directory naming rules discussed above. And, by "distinct", we mean where no other resource set has that qualifier.

If there is no specific resource set that matches, Android chooses the default set — the one with no suffixes on the directory name (e.g., `res/layout/`).

With those rules in mind, let's look at some scenarios, to cover the base case plus the aforementioned exceptions.

Scenario #1: Something Simple

Let's suppose that we have a `main.xml` file in:

- `res/layout-land/`
- `res/layout/`

When we call `setContentView(R.layout.main)`, Android will choose the `main.xml` in `res/layout-land/` if the device is in landscape mode. That particular resource set is valid in that case, and it has the most important distinct qualifier (`-land`). If the device is in portrait mode, though, the `res/layout-land/` resource set does not qualify, and so it is tossed out. That leaves us with `res/layout/`, so Android uses that `main.xml` version.

Scenario #2: Disparate Resource Set Categories

It is possible, though bizarre, for you to have a project with `main.xml` in:

- `res/layout-en/`
- `res/layout-land/`
- `res/layout/`

In this case, if the device's locale is set to be English, Android will choose `res/layout-en/`, regardless of the orientation of the device. That is because `-en` is a more important resource set qualifier — "Language and region" appears higher in the "Table 2. Configuration qualifier names" from the Android documentation than does "Screen orientation" (for `-land`). If the device is not set for English, though, Android will toss out that resource set, at which point the decision-making process is the same as in Scenario #1 above.

Scenario #3: Multiple Qualifiers

Now let's envision a project with `main.xml` in:

- `res/layout-en/`
- `res/layout-land-v11/`
- `res/layout/`

You might think that `res/layout-land-v11/` would be the choice, as it is more specific, matching on two resource set qualifiers versus the one or none from the other resource sets.

(in fact, the author of this book thought this was the choice for many years)

In this case, though, language is more important than either screen orientation or Android API level, so the decision-making process is similar to Scenario #2 above: Android chooses `res/layout-en/` for English-language devices, `res/layout-land-v11/` for landscape API Level 11+ devices, or `res/layout/` for everything else.

Scenario #4: Multiple Qualifiers, Revisited

Let's change the resource mix, so now we have a project with `main.xml` in:

- `res/layout-land-night/`
- `res/layout-land-v11/`
- `res/layout/`

Here, while `-land` is the most important resource set qualifier, it is not distinct — we have more than one resource set with `-land`. Hence, we need to check which is the next-most-important resource set qualifier. In this case, that is `-night`, as night mode is a more important category than is Android API level, and so Android will choose `res/layout-land-night/` if the device is in night mode. Otherwise, it will choose `res/layout-land-v11/` if the device is running API Level 11 or higher. If the device is not in night mode and is not running API Level 11 or higher, Android will go with `res/layout/`.

Scenario #5: Screen Density

Now, let's look at the first exception to the rules: screen density.

Android will *always* accept a resource set that contains a screen density, *even if it does not match the density of the device*. If there is an exact density match, of course, Android uses it. Otherwise, it will use what it feels is the next-best match, based upon how far off it is from the device's actual density and whether the other density is higher or lower than the device's actual density.

The reason for this is that for drawable resources, Android will downsample or upsample the image automatically, so the drawable will appear to be the right size, even though you did not provide an image in that specific density.

The catch is two-fold:

1. Android applies this logic to all resources, not just drawables, so even if there is no exact density match on, say, a layout, Android will still choose a resource from another density bucket for the layout
2. As a side-effect of the previous bullet, if you include a density resource set qualifier, Android will ignore any lower-priority resource set qualifiers (unless there are multiple directories with the same density resource set qualifier, in which case the lower-priority qualifiers serve as the "tiebreaker")

So, now let's pretend that our project has `main.xml` in:

- `res/layout-mdpi/`
- `res/layout-nonav/`
- `res/layout/`

Android will choose `res/layout-mdpi/`, even for `-hdpi` devices that do not have a "non-touch navigation method". While `-mdpi` does not match `-hdpi`, Android will still choose `-mdpi`. If we were dealing with drawables resources, Android would upsample the `-mdpi` image.

Scenario #6: Screen Sizes

If you have resource sets tied to screen size, Android will choose the one that is closest to the actual screen size yet smaller than the actual screen size. Resource sets for screen sizes larger than the actual screen size are ignored.

This works for `-swNNNdp`, `-wNNNdp`, and `-hNNNdp` for all devices. On `-large` or `-xlarge` devices, Android applies the same logic for the classic screen size qualifiers (`-small`, `-normal`, `-large`, `-xlarge`). However, Android does *not* apply this logic for `-small` or `-normal` devices — a `-normal` device will not load a `-small` resource.

Now let's pretend that our project has `main.xml` in:

- `res/layout-normal/`
- `res/layout-land/`
- `res/layout/`

Android will choose `res/layout-normal/` if the device is not `-small`. Otherwise, Android will choose `res/layout-land/` if the device is landscape. If all else fails, Android will choose `res/layout/`.

Similarly, if we have:

- `res/layout-w320dp/`
- `res/layout-land/`
- `res/layout/`

Android will choose `res/layout-w320dp/` for devices whose current screen width is 320dp or higher. Otherwise, Android will choose `res/layout-land/` if the device is landscape. If all else fails, Android will choose `res/layout/`.

API-Versioned Resources

As noted previously in this chapter, the `-vNNN` set of suffixes indicate that the resources in that directory are for the stated API level or higher. So, for example, `res/values-v21/` indicates that the resources in that directory should only be used on API Level 21 (Android 5.0) and higher. Devices running older versions of Android will ignore those resources.

This is a particularly important set of suffixes for dealing with major Android version changes. The look and feel of a stock Android app changed significantly at API Level 11 (Android 3.0) and API Level 21 (Android 5.0). You may find that you want to have different resources starting at those API level split points, so that your UI looks appropriate on all versions of Android that you are supporting.

Use Case: Themes by API Level

One big use case for this feature is having different themes by API level.

Even if your `minSdkVersion` is 11 or higher, you may want to have two different themes for your app:

- One, used from API Level 11-20, based on `Theme.Holo`
- Another, used from API Level 21 onwards, based on `Theme.Material`

Your rough alternative is to use the `appcompat-v7` backport of the action bar and bits of the Material Design aesthetic. For highly stylized apps, or in cases where you are sure that you want Material Design on pre-Android 5.0 devices, `appcompat-v7` is worth considering. But if you want to blend in better on each major native UI variant, you will want to support `Theme.Holo` on Android 3.x and 4.x and `Theme.Material` after that.

The hard work here is setting up your themes themselves, such as what was outlined back in the chapter on the action bar. Having them both be available, depending upon device version, is merely a matter of putting the resources into the proper directories.

For example, take a look at the `ActionBar/VersionedColor` sample project. This is a "mashup" of the `HoloColor` and `MaterialColor` sample projects, where the determination of which theme to use is based on API level.

In the `res/values/` directory, we have a `styles.xml` file that is the same as the one in the `HoloColor` example, just with the filename standardized to `styles.xml`. It uses a custom theme (`Theme.Apptheme`) generated by the Action Bar Style Generator.

There is also a `res/values-v21/` directory, indicating values resources to be used on API Level 21 and higher. It has the theme originally seen in the `MaterialColor` example, where the style resource is renamed to `Theme.Apptheme`, to match the one defined in `res/values/`.

Then, with `<application>` referencing `Theme.Apptheme`, we get the right action bar on the right device.

Here, having the style resources names be the same is important, as we are referencing the name in the `<application>` element in the manifest. To be able to pull in the right one, we need them both to have the same name. However, resources that are referred to by only one of those themes, such as color and drawable resources, could go in a versioned directory or not, as you see fit. They *have* to go in versioned directories and *have* to have the same names if you want multiple editions where the API level chooses which edition to use.

For example, the `Theme.Material`-based theme defined in `res/values-v21/styles.xml` references three color resources. The file for those resources happens to

also be in `res/values-v21/` (`colors.xml`). However, since we are not looking to replace those colors based on API level, the `colors.xml` file could be placed in `res/values/` and work just as well. And, if we *did* want to have different colors by API level, we would need those colors defined in all relevant resource sets, such as both `res/values/` *and* `res/values-v21/`.

Default Change Behavior

When you call methods in the Android SDK that load a resource (e.g., the aforementioned `setContentView(R.layout.main)`), Android will walk through those resource sets, find the right resource for the given request, and use it.

But what happens if the configuration changes *after* we asked for the resource? For example, what if the user was holding their device in portrait mode, then rotates the screen to landscape? We would want a `-land` version of our layouts, if such versions exist. And, since we already requested the resources, Android has no good way of handing us revised resources on the fly... except by forcing us to re-request those resources.

So, this is what Android does, by default, to our foreground activity, when the configuration changes on the fly.

Destroy and Recreate the Activity

The biggest thing that Android does is destroy and recreate our activity. In other words:

- Android calls `onPause()`, `onStop()`, and `onDestroy()` on our original instance of the activity
- Android creates a brand new instance of the same activity class, using the same `Intent` that was used to create the original instance
- Android calls `onCreate()`, `onStart()`, and `onResume()` of the new activity instance
- The new activity appears on the screen

This may seem... invasive. You might not expect that Android would wipe out a perfectly good activity, just because the user flicked her wrist and rotated the screen of her phone. However, this is the only way Android has that guarantees that we will re-request all our resources.

Rebuild the Fragments

If your activity is using fragments, the new instance of the activity will contain the same fragments that the old instance of the activity does. This includes both static and dynamic fragments.

By default, Android destroys and recreates the fragments, just as it destroys and recreates the activities. However, as we will see, we do have an option to tell Android to retain certain dynamic fragment instances — for those, it will have the new instance use the same fragment instances as were used by the old activity, instead of creating new instances from scratch.

Recreate the Views

Regardless of whether or not Android recreates all of the fragments, it will call `onCreateView()` on all of the fragments (plus call `onDestroyView()` on the original set of fragments). In other words, Android recreates all of the widgets and containers, to pour them into the new activity instance.

Retain Some Widget State

Android will hold onto the "instance state" of some of the widgets we have in our activity and fragments. Mostly, it holds onto obviously user mutable state, such as:

- What has been typed into an `EditText`
- Whether a `CompoundButton`, like a `CheckBox` or `RadioButton`, is checked or not
- Etc.

Android will collect this information from the widgets of the old activity instance, carry that data forward to the new activity instance, and update the new set of widgets to have that same state.

However:

- Widgets need to have an ID to have their state saved. If you are inflating the widgets from a layout resource, and the widgets have `android:id` values, you meet this requirement. If, however, you are creating the widgets directly in Java code, those widgets do *not* have an ID. You would need to call `setId()`

to give them an ID or manage the state yourself (using the `onSaveInstanceState()` technique described later in this chapter).

- The ID values need to be unique. If there are several widgets with the same ID, you will run into problems. Usually, the only cases where we have several widgets with the same ID is when those widgets come from an adapter, such as an `ArrayAdapter`. And, usually, those widgets are read-only and do not have any state to save. However, if you attempt putting user-modifiable widgets in the layouts inflated by the adapter, or you otherwise have multiple user-modifiable widgets with the same ID, you will need to manage the state yourself (again, using the `onSaveInstanceState()` technique described later in this chapter).

State Saving Scenarios

When the user rotates the screen, or puts the device in a car dock, or changes the language of the device, your process is not terminated. Your foreground activity will be re-created by default — as will your widgets and fragments — but the process sticks around.

However, there are plenty of cases when your process will be terminated once you move into the background. That might be done automatically by Android or manually by the user.

Depending on *how* your process is terminated, there may be ways that the user can return to your app and expect that they will return to it just how they left it. For example, suppose the user is in your app, then presses HOME to move your app to the background. Hours pass, and Android terminates your process to free up memory for other apps. Sometime after that, the user brings up the recent-tasks list and taps on your app in that list. From the *user's* perspective, they should be returning to your app in the same state that they left it when they pressed HOME. However, if your process was terminated, by default you lost all that state.

Some of the techniques for dealing with a configuration change — those involving the "saved instance state `Bundle`" — will *also* help you handle the recent-tasks-list scenario. Some of the other techniques — such as retaining a fragment — only help with handling configuration changes and will do nothing for you in terms of the recent-tasks-list scenario. The general rule of thumb, therefore, is to use the `Bundle` where you can, and use other techniques (e.g., retained fragments) where the `Bundle` is inappropriate or inadequate. We will see those techniques in the next section.

However, bear in mind that all of this state is designed for transient data, data that the user will not mind if they never see again. For example, suppose the user is in your app, then presses HOME to move your app to the background. Hours pass, and due to the user having busily used their device, *you "fall off" the recent-tasks list*, as that list will not extend indefinitely. In this case, if the user starts up your app again (e.g., via the home screen launcher icon), you will *not* get any state information back for use. Data that the user filled into the old app instance, where that data *must be remembered* and reused in any future run of your app, will need to be persisted yourself, in a database or other type of file.

With all of that in mind, let's examine our options for dealing with the transient state, with an emphasis on configuration changes.

Your Options for Configuration Changes

As noted, a configuration change is fairly invasive on your activity, replacing it outright with all new content (albeit with perhaps some information from the old activity's widgets carried forward into the new activity's widgets).

Hence, you have several possible approaches for handling configuration changes in any given activity.

Do Nothing

The easiest thing to do, of course, is to do nothing at all. If all your state is bound up in stuff Android handles automatically, you do not need to do anything more than the defaults.

For example, the `ViewPager/Fragments` demo from the preceding chapter works correctly "out of the box". All of our "state" is tied up in `EditText` widgets, which Android handles automatically. So, we can type in stuff in a bunch of those widgets, rotate the screen (e.g., via ^[Ctrl>-<Right]^ in the emulator on a Windows or Linux PC), and our entered text is retained.

Alas, there are plenty of cases where the built-in behavior is either incomplete or simply incorrect, and we will need to do more work to make sure that our configuration changes are handled properly.

Retain Your Fragments

One approach for handling these sorts of configuration changes is to have Android retain a dynamic fragment.

Here, "retain" means that Android will keep the same fragment instance across the configuration change, detaching it from the original hosting activity and attaching it to a new hosting activity. Since it is the same fragment instance, anything contained inside that instance is itself retained and, therefore, is not lost when the activity is destroyed and recreated.

To see this in action, take a look at the `ConfigChange/Fragments` sample project.

The business logic for this demo (and for all the other demos in this chapter) is that we want to allow the user to pick a contact out of the roster of contacts found on their device or emulator. We will do that by having the user press a "Pick" button, at which time we will display an activity that will let the user pick the contact and return the result to us. Then, we will enable a "View" button, and let the user view the details of the selected contact. The key is that our selected contact needs to be retained across configuration changes — otherwise, the user will rotate the screen, and the activity will appear to forget about the chosen contact.

The activity itself just loads the dynamic fragment, following the recipe seen previously in this book:

```
package com.commonsware.android.rotation.frag;

import android.app.Activity;
import android.os.Bundle;

public class RotationFragmentDemo extends Activity {
  @Override
  public void onCreate(Bundle savedInstanceState) {
    super.onCreate(savedInstanceState);

    if (getFragmentManager().findFragmentById(android.R.id.content)==null) {
      getFragmentManager().beginTransaction()
                                  .add(android.R.id.content,
                                       new RotationFragment()).commit();
    }
  }
}
```

(from ConfigChange/Fragments/app/src/main/java/com/commonsware/android/rotation/frag/RotationFragmentDemo.java)

The reason for checking for the fragment's existence should now be clearer. Since Android will automatically recreate (or retain) our fragments across configuration changes, we do not want to create a *second* copy of the same fragment when we already have an existing copy.

The fragment is going to use an `R.layout.main` layout resource, with two implementations. One, in `res/layout-land/`, will be used in landscape:

```
<?xml version="1.0" encoding="utf-8"?>
<LinearLayout xmlns:android="http://schemas.android.com/apk/res/android"
  android:orientation="horizontal"
  android:layout_width="match_parent"
  android:layout_height="match_parent"
  >
  <Button android:id="@+id/pick"
    android:layout_width="match_parent"
    android:layout_height="match_parent"
    android:layout_weight="1"
    android:text="@string/pick"
    android:enabled="true"
  />
  <Button android:id="@+id/view"
    android:layout_width="match_parent"
    android:layout_height="match_parent"
    android:layout_weight="1"
    android:text="@string/view"
    android:enabled="false"
  />
</LinearLayout>
```

(from ConfigChange/Fragments/app/src/main/res/layout-land/main.xml)

The portrait edition, in `res/layout/`, is identical save for the orientation of the `LinearLayout`:

```
<?xml version="1.0" encoding="utf-8"?>
<LinearLayout xmlns:android="http://schemas.android.com/apk/res/android"
  android:orientation="vertical"
  android:layout_width="match_parent"
  android:layout_height="match_parent"
  >
  <Button android:id="@+id/pick"
    android:layout_width="match_parent"
    android:layout_height="match_parent"
    android:layout_weight="1"
```

```
    android:text="@string/pick"
    android:enabled="true"
  />
  <Button android:id="@+id/view"
    android:layout_width="match_parent"
    android:layout_height="match_parent"
    android:layout_weight="1"
    android:text="@string/view"
    android:enabled="false"
  />
</LinearLayout>
```

(from ConfigChange/Fragments/app/src/main/res/layout/main.xml)

Here is the complete implementation of `RotationFragment`:

```
package com.commonsware.android.rotation.frag;

import android.app.Activity;
import android.app.Fragment;
import android.content.Intent;
import android.net.Uri;
import android.os.Bundle;
import android.provider.ContactsContract;
import android.view.LayoutInflater;
import android.view.View;
import android.view.ViewGroup;

public class RotationFragment extends Fragment implements
    View.OnClickListener {
  static final int PICK_REQUEST=1337;
  Uri contact=null;

  @Override
  public View onCreateView(LayoutInflater inflater, ViewGroup parent,
                           Bundle savedInstanceState) {
    setRetainInstance(true);

    View result=inflater.inflate(R.layout.main, parent, false);

    result.findViewById(R.id.pick).setOnClickListener(this);

    View v=result.findViewById(R.id.view);

    v.setOnClickListener(this);
    v.setEnabled(contact != null);
```

```
    return(result);
  }

  @Override
  public void onActivityResult(int requestCode, int resultCode,
                               Intent data) {
    if (requestCode == PICK_REQUEST) {
      if (resultCode == Activity.RESULT_OK) {
        contact=data.getData();
        getView().findViewById(R.id.view).setEnabled(true);
      }
    }
  }

  @Override
  public void onClick(View v) {
    if (v.getId() == R.id.pick) {
      pickContact(v);
    }
    else {
      viewContact(v);
    }
  }

  public void pickContact(View v) {
    Intent i=
        new Intent(Intent.ACTION_PICK,
                   ContactsContract.Contacts.CONTENT_URI);

    startActivityForResult(i, PICK_REQUEST);
  }

  public void viewContact(View v) {
    startActivity(new Intent(Intent.ACTION_VIEW, contact));
  }
}
```

(from ConfigChange/Fragments/app/src/main/java/com/commonsware/android/rotation/frag/RotationFragment.java)

In `onClick()`, we hook up the "Pick" button to a `pickContact()` method. There, we call `startActivityForResult()` with an `ACTION_PICK` `Intent`, indicating that we want to pick something from the `ContactsContract.Contacts.CONTENT_URI` collection of contacts. We will discuss `ContactsContract` in greater detail later in this book. For the moment, take it on faith that Android has such an `ACTION_PICK` activity, one that will display to the user the list of available contacts:

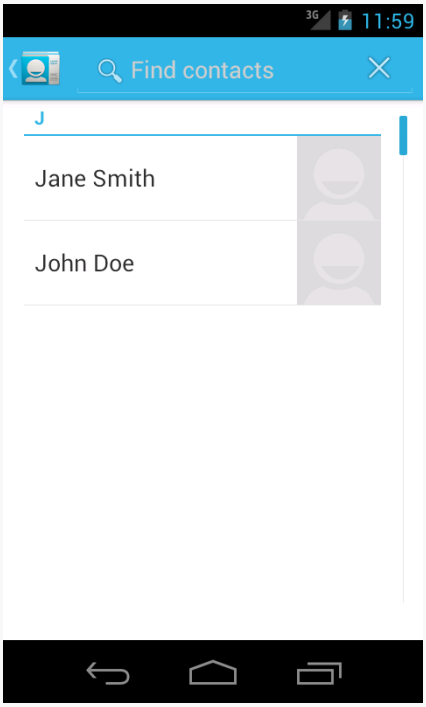

Figure 248: ACTION_PICK of a Contact

In addition to the `ACTION_PICK` `Intent`, we also supply a unique `int` to `startActivityForResult()`. This `int` should be a 16-bit value (`0` to `65535`) that is unique for this particular `startActivityForResult()` call from this activity. This value does not have to be unique compared to such calls from other activities of yours, let alone across the entire device.

If the user picks a contact, control returns to our activity, with a call to `onActivityResult()`. `onActivityResult()` is passed:

- the unique ID we supplied to `startActivityForResult()`, to help identify this result from any others we might be receiving
- `RESULT_OK` if the user did pick a contact, or `RESULT_CANCELED` if the user abandoned the pick activity
- an `Intent` containing the result from the pick activity, which, in this case, will contain a `Uri` representing the selected contact, retrieved via `getData()`

We store that `Uri` in a data member, plus we enable the "View" button, which, when clicked, will bring up an `ACTION_VIEW` activity on the selected contact via its `Uri`:

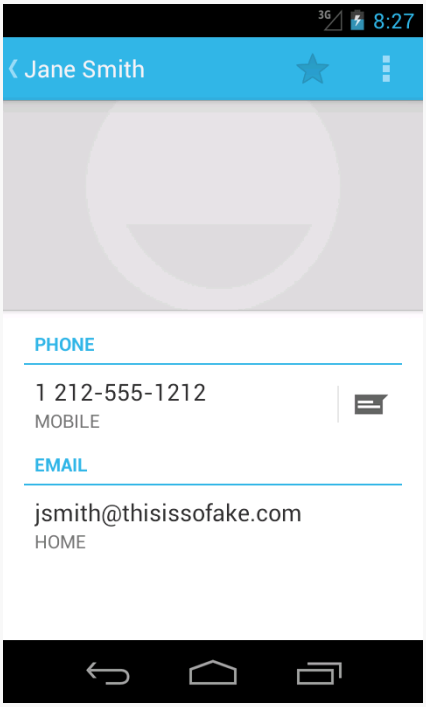

Figure 249: ACTION_VIEW of a Contact

Up in `onCreateView()`, we called `setRetainInstance(true)`. This tells Android to keep this fragment instance across configuration changes. Hence, we can pick a contact in portrait mode, then rotate the screen (e.g., ^[Ctrl>-<Right]^ in the emulator on Windows or Linux), and view the contact in landscape mode. Even though the activity and the buttons were replaced as a result of the rotation, the fragment was not, and the fragment held onto the `Uri` of the selected contact.

Note that `setRetainInstance()` only works with dynamic fragments, not static fragments. Static fragments are always recreated when the activity is itself destroyed and recreated.

The benefit of this technique, over others, is that you can retain any sort of data you want: any data type, any size, etc. However, this approach does not save state that will be given back to you after your process had been terminated, such as when the user goes back to your app via the recent-tasks list.

Model Fragment

A variation on this theme is the "model fragment". While fragments normally are focused on supplying portions of the UI to a user, that is not really a requirement. A

model fragment is one that simply uses `setRetainInstance(true)` to ensure that it sticks around as configurations change. This fragment then holds onto any model data that its host activity needs, so as that activity gets destroyed and recreated, the model data sticks around in the model fragment.

This is particularly useful for data that might not otherwise have a fragment home. For example, imagine an activity whose UI consists entirely of a `ViewPager`, like the tutorial app. Even though that `ViewPager` might hold fragments, there will be many pages in most pagers. It may be simpler to add a separate, UI-less model fragment and have it hold the activity's data model for the `ViewPager`. This allows the activity to still be destroyed and recreated, and even allows the `ViewPager` to be destroyed and recreated, while still retaining the already-loaded data.

Google recommends using a model fragment instead of using `setRetainInstance(true)` with a regular fragment. The less the retained fragment holds, the less likely it is that you will hold something that you should not be holding, such as a string that needs to be reloaded from a string resource due to a possible locale change. That being said, if you are careful and make sure that all your data members are accounted for properly, using `setRetainInstance(true)` from any fragment can be made safe.

Add to the Bundle

If you want state to be maintained not only for configuration changes, but also for process terminations, you will want to use `onSaveInstanceState()` and `onRestoreInstanceState()`.

You can override `onSaveInstanceState()` in your activity. It is passed a `Bundle`, into which you can store data that should be maintained across the configuration change. The catch is that while `Bundle` looks a bit like it is a `HashMap`, it actually cannot hold arbitrary data types, which limits the sort of information you can retain via `onSaveInstanceState()`. `onSaveInstanceState()` is called around the time of `onPause()` and `onStop()`.

The widget state maintained automatically by Android is via the built-in implementation of `onSaveInstanceState()`. If you override it yourself, typically you will want to chain to the superclass to get this inherited behavior, in addition to putting things into the `Bundle` yourself.

That `Bundle` is passed back to you in two places:

- onCreate()
- onRestoreInstanceState()

Since onCreate() is called in many cases other than due to a configuration change, frequently the passed-in Bundle is null. onRestoreInstanceState(), on the other hand, is only called when there is a Bundle to be used.

To see how this works, take a look at the ConfigChange/Bundle sample project.

Here, RotationBundleDemo is an activity with all the same core business logic as was in our fragment in the preceding demo. Since the activity will be destroyed and recreated on a configuration change, we override onSaveInstanceState() and onRestoreInstanceState() to retain our contact, if one was selected prior to the configuration change:

```
@Override
protected void onSaveInstanceState(Bundle outState) {
  super.onSaveInstanceState(outState);

  if (contact != null) {
    outState.putParcelable("contact", contact);
  }
}

@Override
protected void onRestoreInstanceState(Bundle state) {
  super.onRestoreInstanceState(state);

  contact=state.getParcelable("contact");
  viewButton.setEnabled(contact != null);
}
```

(from ConfigChange/Bundle/app/src/main/java/com/commonsware/android/rotation/bundle/RotationBundleDemo.java)

Here, we use putParcelable() to put the Uri into the Bundle. Parcelable is an interface that you can implement on a Java class to allow an instance of it to be put into a Bundle. Uri happens to implement Parcelable. The full details of what Parcelable means and how you can make things implement Parcelable are provided later in this book.

The downside of this approach is that not everything can go into a Bundle. A Bundle cannot hold arbitrary data types, so you cannot put a Socket into a Bundle, for example. Also, this Bundle needs to be fairly small, as it is passed across process

boundaries, so you cannot put large objects (e.g., bitmaps) into the `Bundle`. For those cases, you will have to settle for the retained-fragment approach.

Fragments *and* a Bundle

Fragments also have an `onSaveInstanceState()` method that they can override. It works just like the `Activity` equivalent — you can store data in the supplied `Bundle` that will be supplied back to you later on. The biggest difference is that there is no `onRestoreInstanceState()` method — instead, you are handed the `Bundle` in other lifecycle methods:

- `onCreate()`
- `onCreateView()`
- `onViewCreated()`
- `onActivityCreated()`

We can see this in the ConfigChange/FragmentBundle sample project. This is effectively a mashup of the previous two samples: using fragments, but also using `onSaveInstanceState()` instead of `setRetainInstance(true)`.

Our `RotationFragment` now has an `onSaveInstanceState()` method that looks a lot like the one from the `ConfigChange/Bundle` sample's activity:

```
@Override
public void onSaveInstanceState(Bundle outState) {
  super.onSaveInstanceState(outState);

  if (contact != null) {
    outState.putParcelable("contact", contact);
  }
}
```

(from ConfigChange/FragmentBundle/app/src/main/java/com/commonsware/android/rotation/fragbundle/RotationFragment.java)

Our `onCreateView()` method examines the passed-in `Bundle`, and if it is not `null` tries to obtain our `contact` from it:

```
@Override
public View onCreateView(LayoutInflater inflater, ViewGroup parent,
                         Bundle state) {
  View result=inflater.inflate(R.layout.main, parent, false);

  result.findViewById(R.id.pick).setOnClickListener(this);
```

```
    View v=result.findViewById(R.id.view);

    v.setOnClickListener(this);

    if (state != null) {
      contact=(Uri)state.getParcelable("contact");
    }

    v.setEnabled(contact != null);

    return(result);
  }
```

(from ConfigChange/FragmentBundle/app/src/main/java/com/commonsware/android/rotation/fragbundle/RotationFragment.java)

This does not allow our fragment to hold onto arbitrary data, the way `setRetainInstance(true)` does. However, as with `onSaveInstanceState()` at the activity level, there are scenarios that `onSaveInstanceState()` handles that retained fragments will not, such as terminating your process due to low memory, yet the user later uses BACK to return to what should have been your activity (and its fragments).

onRetainNonConfigurationInstance()

If you were to go back to early versions of this book, one of the options discussed in this chapter was `onRetainNonConfigurationInstance()`. That approach was deprecated in API Level 11, replaced with retained fragments.

However, in an unprecedented move, Google un-deprecated `onRetainNonConfigurationInstance()` in API Level 24, making it safe for use again.

Despite the really long method name, its use is simple:

- Implement `onRetainNonConfigurationInstance()` on your `Activity`, returning (nearly) any object you want.
- In `onCreate()` of your `Activity`, call `getLastNonConfigurationInstance()`. If it is not `null`, then it is the same object that you returned from `onRetainNonConfigurationInstance()` milliseconds ago, as part of a configuration change. You can cast the `getLastNonConfigurationInstance()` return value to the appropriate type, save it in a field (or whatever), and use it however you were using it in the previous activity instance.

If you need more than one object to be retained this way, simply have `onRetainNonConfigurationInstance()` wrap up the objects in some data structure of your own design.

The ConfigChange/Retain sample project is nearly identical to the `ConfigChange/Bundle` example shown earlier. In this case, the saved instance state `Bundle` was replaced with a retained object. Since `onRetainNonConfigurationInstance()` can return an object of any type, we can just return the `Uri` representing our contact directly:

```
@Override
public Object onRetainNonConfigurationInstance() {
  return(contact);
}
```

(from ConfigChange/Retain/app/src/main/java/com/commonsware/android/rotation/retain/RotationRetainDemo.java)

In `onCreate()`, we set `contact` to be the result of `getLastNonConfigurationInstance()` (casting it to a `Uri`) and update the `viewButton` to reflect whether or not `contact` is `null`:

```
@Override
public void onCreate(Bundle savedInstanceState) {
  super.onCreate(savedInstanceState);
  setContentView(R.layout.main);

  viewButton=(Button)findViewById(R.id.view);
  contact=(Uri)getLastNonConfigurationInstance();
  viewButton.setEnabled(contact != null);
}
```

(from ConfigChange/Retain/app/src/main/java/com/commonsware/android/rotation/retain/RotationRetainDemo.java)

When the user rotates the screen, the `Uri` is passed from the old activity instance to the new one, and so we remember our previously-selected contact.

Under the covers, retained fragments uses `onRetainNonConfigurationInstance()` and `getLastNonConfigurationInstance()`.

As a result, the limitations on `onRetainNonConfigurationInstance()` are reminiscent to the limitations on retained fragments:

- Do not return any `Views` from `onRetainNonConfigurationInstance()`, as they will be tied to the old activity instance, not the new one

- Do not return any objects that might need to be replaced due to the configuration change (e.g., strings generated from string resources)
- Do not use this to *replace* the saved instance state `Bundle` — which also handles other scenarios, such as process termination — but instead use it for things that cannot go into that `Bundle` due to size or data type

NOTE: If you try using `onRetainNonConfigurationInstance()`, and it shows up with the deprecation strikethrough formatting in your IDE, your `compileSdkVersion` is somewhere between 11 and 23. Raise it to 24 to clear up the deprecation warning.

DIY

In a few cases, even a retained fragment is insufficient, because transferring and re-applying the state would be too complex or too slow. Or, in some cases, the hardware will get in the way, such as when trying to use the `Camera` for taking pictures — a concept we will cover later in this book.

If you are completely desperate, you can tell Android to *not* destroy and recreate the activity on a configuration change... though this has its own set of consequences. To do this:

- Put an `android:configChanges` entry in your `AndroidManifest.xml` file, listing the configuration changes you want to handle yourself versus allowing Android to handle for you
- Implement `onConfigurationChanged()` in your `Activity`, which will be called when one of the configuration changes you listed in `android:configChanges` occurs

Now, for any configuration change you want, you can bypass the whole activity-destruction process and simply get a callback letting you know of the change.

For example, take a look at the `ConfigChange/DIY` sample project.

In `AndroidManifest.xml`, we add the `android:configChanges` attribute to the `<activity>` element, indicating that we want to handle several configuration changes ourselves:

```
    <activity
      android:name="RotationDIYDemo"
      android:configChanges="keyboardHidden|orientation|screenSize"
      android:label="@string/app_name">
      <intent-filter>
```

```
      <action android:name="android.intent.action.MAIN"/>

      <category android:name="android.intent.category.LAUNCHER"/>
    </intent-filter>
  </activity>
```

(from ConfigChange/DIY/app/src/main/AndroidManifest.xml)

Many recipes for this will have you handle `orientation` and `keyboardHidden`. However, nowadays, you need to also handle `screenSize` (and, in theory, `smallestScreenSize`), if you have your `android:targetSdkVersion` set to 13 or higher. Note that this will require your build target (e.g., `compileSdkVersion` in Android Studio) to be set to 13 or higher.

Hence, for those particular configuration changes, Android will not destroy and recreate the activity, but instead will call `onConfigurationChanged()`. In the `RotationDIYDemo` implementation, this simply toggles the orientation of the `LinearLayout` to match the orientation of the device:

```
@Override
public void onConfigurationChanged(Configuration newConfig) {
  super.onConfigurationChanged(newConfig);

  LinearLayout container=(LinearLayout)findViewById(R.id.container);

  if (newConfig.orientation == Configuration.ORIENTATION_LANDSCAPE) {
    container.setOrientation(LinearLayout.HORIZONTAL);
  }
  else {
    container.setOrientation(LinearLayout.VERTICAL);
  }
}
```

(from ConfigChange/DIY/app/src/main/java/com/commonsware/android/rotation/diy/RotationDIYDemo.java)

Since the activity is not destroyed during a configuration change, we do not need to worry at all about the `Uri` of the selected contact — it is not going anywhere.

The problem with this implementation is twofold:

1. We are not handling all possible configuration changes. If the user, say, puts the device into a car dock, Android will destroy and recreate our activity, and we will lose our selected contact.
2. We might forget some resource that needs to be changed due to a configuration change. For example, if we start translating the strings used by

the layouts, and we include `locale` in `android:configChanges`, we not only need to update the `LinearLayout` but also the captions of the `Button` widgets, since Android will not do that for us automatically.

It is these two problems that are why Google does not recommend the use of this technique unless absolutely necessary.

Also, bear in mind that this approach does not help at all for retaining state when your process is terminated and the user returns to your app via the recent-tasks list.

Blocking Rotations

No doubt that you have seen some Android applications that simply ignore any attempt to rotate the screen. Many games work this way, operating purely in landscape mode, regardless of how the device is positioned.

To do this, add `android:screenOrientation="sensorLandscape"`, or possibly `android:screenOrientation="sensorPortrait"`, to your manifest. The "sensor" portions of those names indicate that your app can work in regular or "reverse" versions of the orientation (e.g., "regular" landscape is the device rotated 90 degrees counter-clockwise from portrait, while "reverse" landscape is the device rotated 90 degrees clockwise from portrait). On API Level 18+, you could use `userLandscape` or `userPortrait` instead, as those will honor the user's system-level choice of whether to lock screen rotation or not, defaulting to the behavior of `sensorLandscape` or `sensorPortrait` if the user has not locked screen rotation.

Also, if you use this to lock one or more of your activities to a particular orientation, also use the corresponding `<uses-feature>` element in your manifest:

- `<uses-feature android:name="android.hardware.screen.portrait"/>` if you have an activity locked to portrait
- `<uses-feature android:name="android.hardware.screen.landscape"/>` if you have an activity locked to landscape

This element would go as a child of the root `<manifest>` element but outside of the `<application>` element.

The role of this `<uses-feature>` element is to advertise to the Play Store and similar app distribution channels that your app requires certain hardware features. Such channels might block distribution of your app to platforms where your required

orientation is not supported (e.g., portrait activities on a TV-centric device like Android TV).

And Now, a Word From the Android Project View

Earlier in the book, when introducing Android Studio, we saw the Android project view.

One of the reasons why the Android project view was created was to help you manage resources, particularly across various resource sets.

For example, here is a screenshot of the same Android project, but this time with the `values` resources expanded in the tree:

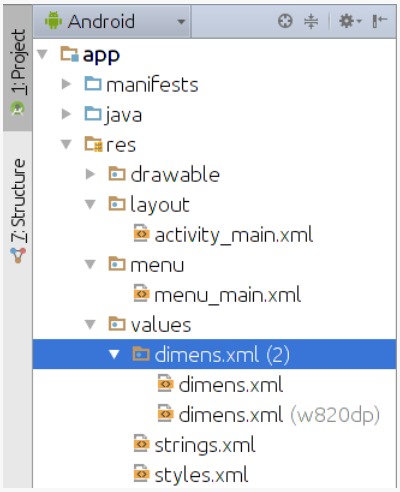

Figure 250: Android Project View, Showing Dimension Resources

The tree makes it appear as though there is just a `res/values/dimens.xml` file... but that the file somehow has children. One child has just the bare `dimens.xml` filename, while the other one has a "(w820dp)" appended.

This reflects the fact that there are two versions of `dimens.xml`: one in `res/values/` and one in `res/values-w820dp/`:

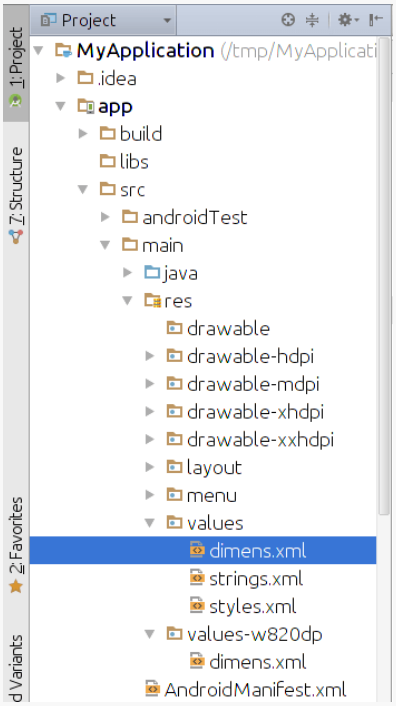

Figure 251: Classic Project View, Showing Dimension Resources

In the Android project view, resources are organized by resource, not by resource set. This can be useful for finding all files that need to be adjusted when you go to adjust one version of the resource, for example.

Configuration Challenges

Some newer Android versions have added new and exciting challenges when dealing with resources and configuration changes.

Multi-Locale Support

Android 7.0+ users can indicate that they support more than one language:

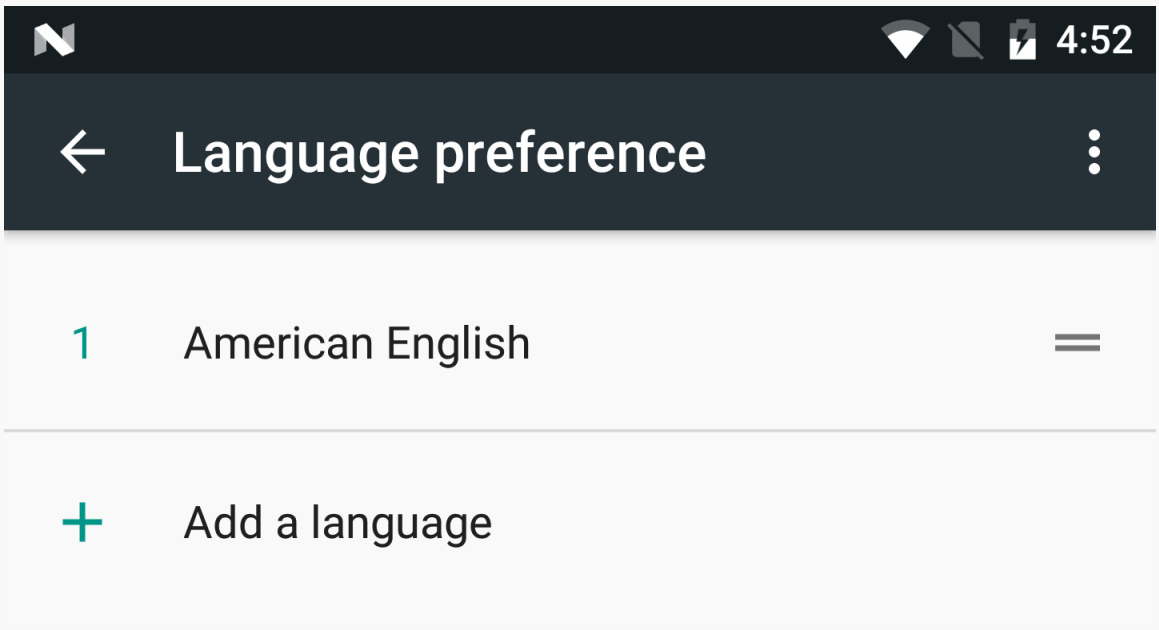

Figure 252: Android 7.0 Language Settings

The user can choose the relative priorities of these languages, by grabbing the handle on the right side of the row and dragging the language higher or lower in the list.

This has impacts on resource resolution for any locale-dependent resources, such as strings. Now Android will check multiple languages for resource matches, before falling back to the default language (e.g., whatever you have in `res/values/strings.xml`). Hence, it is important that you ensure that you have a complete set of strings for every language that you support, lest the user perhaps wind up with a mixed set of languages in the UI.

You can find out what languages the user has requested via a `LocaleList` class and its `getDefault()` `static` method. This, as the name suggests, has a list of `Locale` objects representing the user's preferred languages. If you had previously been using `Locale` alone for this (e.g., for specialized in-app language assistance beyond resources), you will want to switch to `LocaleList` for Android 7.0 and beyond.

Screen Zoom/Dynamic Density

Developers have had the ability to change the effective density of a device, by using `adb` commands. Android 7.0+ users can do this directly from Settings.

In Settings > Display > Display Size, the user can choose five different “display sizes”:

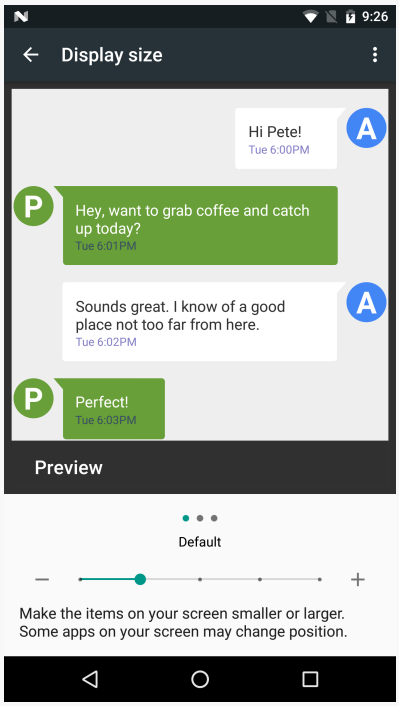

Figure 253: Display Size, Showing Default Setting

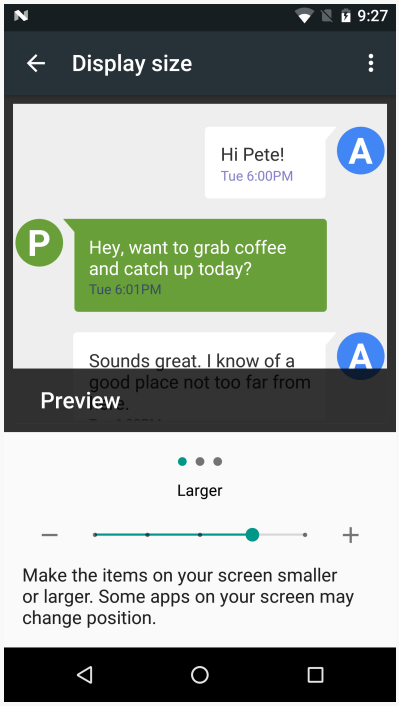

Figure 254: Display Size, Showing "Larger" Setting

While this is described to the user as a "size" or "zoom" setting, in reality it is affecting the apparent screen density, with Android scaling things based on a combination of actual density and the user's stated "display size" preference.

Anything that is already density-independent should work just fine, though you certainly will want to run some tests to ensure that your app is working properly. In fact, this feature makes for a way to easily test your app on a variety of densities, without having to have dedicated hardware for those densities.

If your app is running at the time of the density change, what happens varies:

- Normally, if your `targetSdkVersion` is 23 or below, Android will terminate your process. Since you will be in the background at the time (Settings is in the foreground), this will be little different than if Android terminated your process due to low memory conditions, and your app should already handle this. The documentation suggests that if you have a foreground service, that Android will not terminate the process but instead treat this as a configuration change.
- If your `targetSdkVersion` is 24 or higher, this will be treated as a configuration change for all processes.

For the configuration-change scenarios, if your app is caching information that depends on screen density, be sure to flush those caches and get fresh information based on the new screen density.

Material Design Basics

We have already been exposed to `Theme.Material` as part of this book, such as with the action bar.

Android 5.0+, combined with `Theme.Material`, gives you a lot of capabilities tied to Google's Material Design aesthetic. In this chapter, we will cover some basic Material Design capabilities that will affect your `Theme.Material` app on Android 5.0+, starting with color.

Your App, in Technicolor!

Some developers want to change the colors used by their app to match some specific color or color palette. In some cases, the colors in question are tied to the app's branding. In other cases, the developer simply wants something different than the stock colors you get from something like `Theme.Holo` or `Theme.Holo.Light`.

Affecting color changes in your `Theme.Material`-based Android app is vastly simplified — both for the action bar and the widgets — courtesy of `Theme.Material`'s tinting options.

Basic Tinting Options

In the chapter on the action bar, we saw how to set up a custom theme based on `Theme.Material` that had custom color tinting rules that affected the action bar:

```
<?xml version="1.0" encoding="utf-8"?>
<resources>
  <style name="AppTheme" parent="android:Theme.Material">
    <item name="android:colorPrimary">@color/primary</item>
    <item name="android:colorPrimaryDark">@color/primary_dark</item>
```

```
    <item name="android:colorAccent">@color/accent</item>
  </style>
</resources>
```

(from ActionBar/MaterialColor/app/src/main/res/values/styles.xml)

At that time, we focused on the effects that these tints had on the action bar itself. However, with `Theme.Material`, not only do the tints affect the action bar, but they affect the widgets themselves.

The `BasicMaterial` directory contains clones of some of the basic widget samples outlined earlier in this book, where each includes the custom theme demonstrated for the action bar.

In some cases, the custom tints are not normally visible, such as with a button:

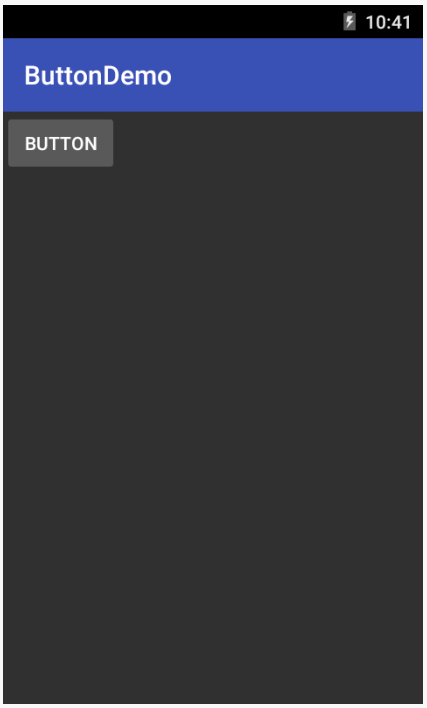

Figure 255: Custom Material Theme for a Button

However, when you tap the button, the animated "ripple" effect shown on the button will use your accent color.

In other cases, the accent color will show up in a more "steady state", such as in a checked `CheckBox`:

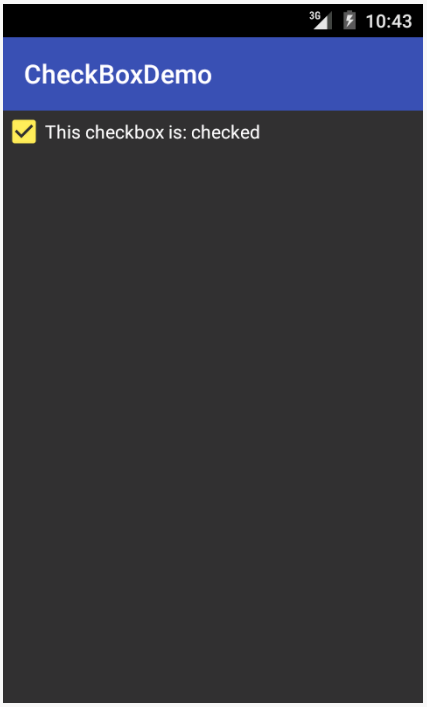

Figure 256: Custom Material Theme for a CheckBox

Similarly, your accent color shows up in things like:

- the "underbar" and drag-cursor in an `EditText`:

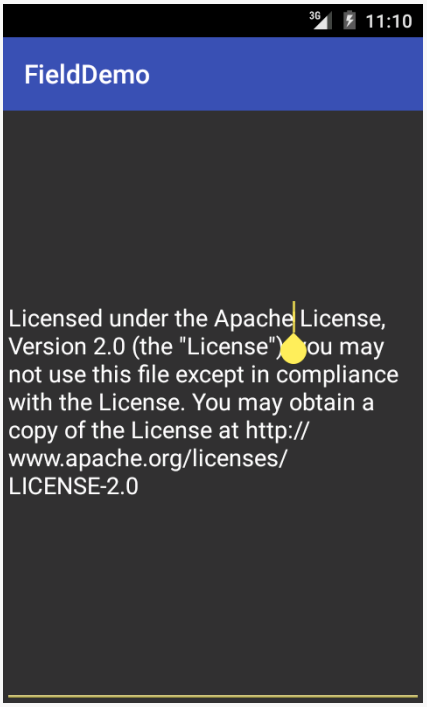

Figure 257: Custom Material Theme for an EditText

- the checked state (and ripple effect when toggling the state) of a `RadioButton`:

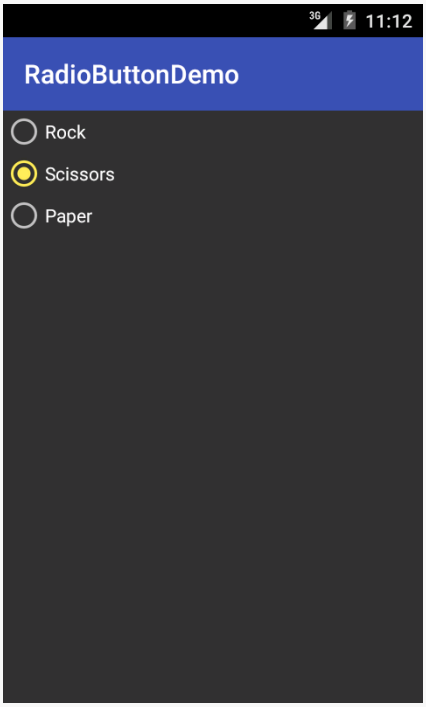

Figure 258: Custom Material Theme for a RadioButton

- and the "checked" state of a `Switch`:

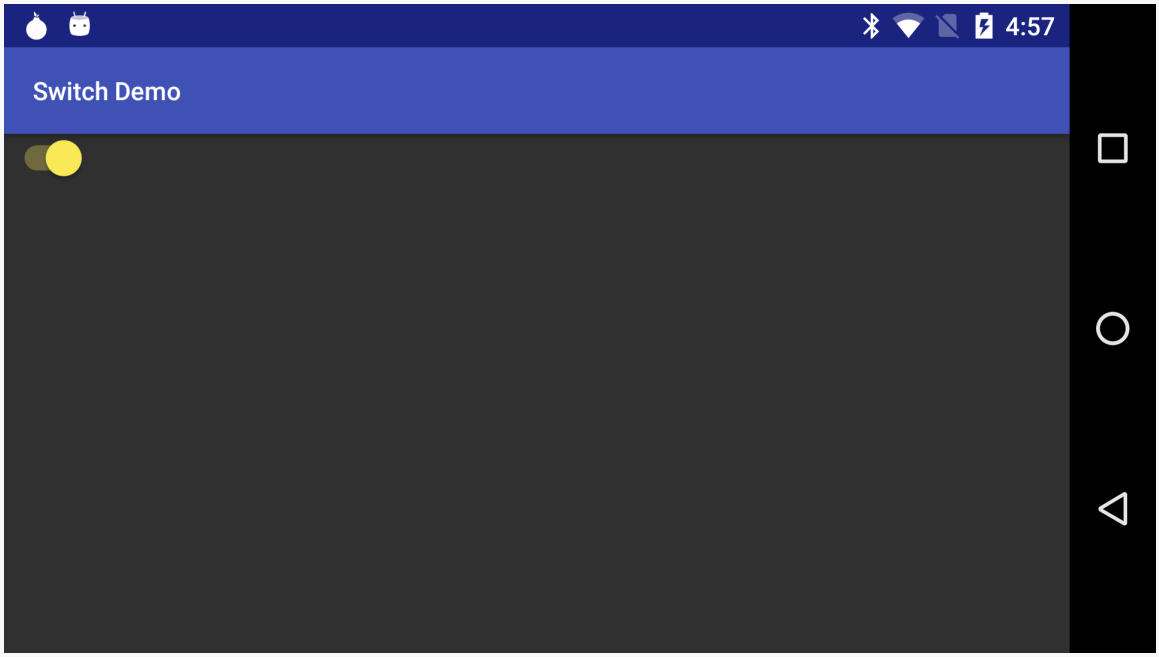

Figure 259: Custom Material Theme for a Switch

Official Google-Approved Colors

Of course, you are welcome to pick whatever colors you like for your theme.

Google has its opinion of what it thinks are good ideas.

As part of the Material Design documentation, you will find a "Color palette" page that outlines possible colors to use.

A Redditor has also published an Android color resource file that contains all of the colors outlined in the Material Design guide.

There is also the material palette site, which generates a color resource file based upon colors that you select from a large grid of color swatches.

Dealing with Threads

Users like snappy applications. Users do not like applications that feel sluggish.

The way to help your application feel snappy is to use the standard threading capabilities built into Android. This chapter will go through the issues involved with thread management in Android and will walk you through some of the options for keeping the user interface crisp and responsive.

The Main Application Thread

When you call `setText()` on a `TextView`, you probably think that the screen is updated with the text you supply, right then and there.

You would be mistaken.

Rather, everything that modifies the widget-based UI goes through a message queue. Calls to `setText()` do not update the screen — they just place a message on a queue telling the operating system to update the screen. The operating system pops these messages off of this queue and does what the messages require.

The queue is processed by one thread, variously called the "main application thread" and the "UI thread". So long as that thread can keep processing messages, the screen will update, user input will be handled, and so on.

However, the main application thread is also used for nearly all callbacks into your activity. Your `onCreate()`, `onClick()`, `onListItemClick()`, and similar methods are all called on the main application thread. While your code is executing in these methods, Android is not processing messages on the queue, and so the screen does not update, user input is not handled, and so on.

This, of course, is bad. So bad, that if you take more than a few seconds to do work on the main application thread, Android may display the dreaded "Application Not Responding" dialog (ANR for short), and your activity may be killed off.

Nowadays, though, the bigger concern is jank.

"Jank", as used in Android, refers to sluggish UI updates, particularly when something is animating. For example, you may have encountered some apps that when you scroll a `ListView` in the app, the `ListView` does not scroll smoothly. Rather, it scrolls jerkily, interleaving periods of rapid movement with periods where the animation is frozen. Most of the time, this is caused by the app's author doing too much work on the main application thread.

Android 4.1 introduced "Project Butter", which, among other things, established a baseline for "doing too much work on the main application thread". We will "drop frames" if we take more than ~16ms per frame (60 frames per second), and dropped frames are the source of jank. Since we may be called many times during a frame, each of our callbacks needs to be very cheap, ideally below 1ms. We will get much more into the issue of jank later in the book, but it is important to understand now that any significant delay in the execution of our code on the main application thread can have visible effects to the user.

Hence, you want to make sure that all of your work on the main application thread happens quickly. This means that anything slow should be done in a background thread, so as not to tie up the main application thread. This includes things like:

1. Internet access, such as sending data to a Web service or downloading an image
2. Significant file operations, since flash storage can be remarkably slow at times
3. Any sort of complex calculations

Fortunately, Android supports threads using the standard `Thread` class from Java, plus all of the wrappers and control structures you would expect, such as the `java.util.concurrent` class package.

However, there is one big limitation: you cannot modify the UI from a background thread. You can only modify the UI from the main application thread. If you call `setText()` on a `TextView` from a background thread, your application will crash, with an exception indicating that you are trying to modify the UI from a "non-UI thread" (i.e., a thread other than the main application thread).

This is a pain.

Getting to the Background

Hence, you need to get long-running work moved into background threads, but those threads need to do something to arrange to update the UI using the main application thread.

There are various facilities in Android for helping with this.

Some are high-level frameworks for addressing this issue for major functional areas. One example of this is the `Loader` framework for retrieving information from databases, and we will examine this in a later chapter.

Sometimes, there are asynchronous options built into other Android operations. For example, when we discuss `SharedPreferences` in a later chapter, we will see that we can persist changes to those preferences synchronously or asynchronously.

And, there are a handful of low-level solutions for solving this problem, ones that you can apply for your own custom business logic.

Asyncing Feeling

One popular approach for handling this threading problem is to use `AsyncTask`. With `AsyncTask`, Android will handle all of the chores of coordinating separate work done on a background thread versus on the UI thread. Moreover, Android itself allocates and removes that background thread. And, it maintains a small work queue, further accentuating the "fire and forget" feel to `AsyncTask`.

The Theory

Theodore Levitt is quoted as saying, with respect to marketing: "People don't want to buy a quarter-inch drill, they want a quarter-inch hole". Hardware stores cannot sell holes, so they sell the next-best thing: devices (drills and drill bits) that make creating holes easy.

Similarly, many Android developers who have struggled with background thread management do not want background threads — they want work to be done off the UI thread, to avoid jank. And while Android cannot magically cause work to not

consume UI thread time, Android can offer things that make such background operations easier and more transparent. `AsyncTask` is one such example.

To use `AsyncTask`, you must:

1. Create a subclass of `AsyncTask`
2. Override one or more `AsyncTask` methods to accomplish the background work, plus whatever work associated with the task that needs to be done on the UI thread (e.g., update progress)
3. When needed, create an instance of the `AsyncTask` subclass and call `execute()` to have it begin doing its work

What you do *not* have to do is:

1. Create your own background thread
2. Terminate that background thread at an appropriate time
3. Call all sorts of methods to arrange for bits of processing to be done on the UI thread

AsyncTask, Generics, and Varargs

Creating a subclass of `AsyncTask` is not quite as easy as, say, implementing the `Runnable` interface. `AsyncTask` uses generics, and so you need to specify three data types:

1. The type of information that is needed to process the task (e.g., URLs to download)
2. The type of information that is passed within the task to indicate progress
3. The type of information that is passed when the task is completed to the post-task code

What makes this all the more confusing is that the first two data types are actually used as varargs, meaning that an array of these types is used within your `AsyncTask` subclass.

This should become clearer as we work our way towards an example.

The Stages of AsyncTask

There are four methods you can override in `AsyncTask` to accomplish your ends.

The one you must override, for the task class to be useful, is `doInBackground()`. This will be called by `AsyncTask` on a background thread. It can run as long as it needs to in order to accomplish whatever work needs to be done for this specific task. Note, though, that tasks are meant to be finite – using `AsyncTask` for an infinite loop is not recommended.

The `doInBackground()` method will receive, as parameters, a varargs array of the first of the three data types listed above — the data needed to process the task. So, if your task's mission is to download a collection of URLs, `doInBackground()` will receive those URLs to process.

The `doInBackground()` method must return a value of the third data type listed above — the result of the background work.

You may wish to override `onPreExecute()`. This method is called, from the UI thread, before the background thread executes `doInBackground()`. Here, you might initialize a `ProgressBar` or otherwise indicate that background work is commencing.

Also, you may wish to override `onPostExecute()`. This method is called, from the UI thread, after `doInBackground()` completes. It receives, as a parameter, the value returned by `doInBackground()` (e.g., success or failure flag). Here, you might dismiss the `ProgressBar` and make use of the work done in the background, such as updating the contents of a list.

In addition, you may wish to override `onProgressUpdate()`. If `doInBackground()` calls the task's `publishProgress()` method, the object(s) passed to that method are provided to `onProgressUpdate()`, but in the UI thread. That way, `onProgressUpdate()` can alert the user as to the progress that has been made on the background work. The `onProgressUpdate()` method will receive a varargs of the second data type from the above list — the data published by `doInBackground()` via `publishProgress()`.

A Sample Task

As mentioned earlier, implementing an `AsyncTask` is not quite as easy as implementing a `Runnable`. However, once you get past the generics and varargs, it is not too bad.

To see an `AsyncTask` in action, this section will examine the `Threads/AsyncTask` sample project.

The Fragment and its AsyncTask

We have a `ListFragment`, named `AsyncDemoFragment`:

```
package com.commonsware.android.async;

import android.support.v4.app.ListFragment;
import android.os.AsyncTask;
import android.os.Bundle;
import android.os.SystemClock;
import android.view.View;
import android.widget.ArrayAdapter;
import android.widget.Toast;
import java.util.ArrayList;

public class AsyncDemoFragment extends ListFragment {
  private static final String[] items= { "lorem", "ipsum", "dolor",
      "sit", "amet", "consectetuer", "adipiscing", "elit", "morbi",
      "vel", "ligula", "vitae", "arcu", "aliquet", "mollis", "etiam",
      "vel", "erat", "placerat", "ante", "porttitor", "sodales",
      "pellentesque", "augue", "purus" };
  private ArrayList<String> model=new ArrayList<String>();
  private ArrayAdapter<String> adapter=null;
  private AddStringTask task=null;

  @Override
  public void onCreate(Bundle savedInstanceState) {
    super.onCreate(savedInstanceState);

    setRetainInstance(true);

    task=new AddStringTask();
    task.execute();

    adapter=
      new ArrayAdapter<>(getActivity(),
        android.R.layout.simple_list_item_1,
        model);
  }

  @Override
  public void onViewCreated(View v, Bundle savedInstanceState) {
    super.onViewCreated(v, savedInstanceState);

    getListView().setScrollbarFadingEnabled(false);
    setListAdapter(adapter);
  }
```

```
  @Override
  public void onDestroy() {
    if (task != null) {
      task.cancel(false);
    }

    super.onDestroy();
  }

  class AddStringTask extends AsyncTask<Void, String, Void> {
    @Override
    protected Void doInBackground(Void... unused) {
      for (String item : items) {
        if (isCancelled())
          break;

        publishProgress(item);
        SystemClock.sleep(400);
      }

      return(null);
    }

    @Override
    protected void onProgressUpdate(String... item) {
      if (!isCancelled()) {
        adapter.add(item[0]);
      }
    }

    @Override
    protected void onPostExecute(Void unused) {
      Toast.makeText(getActivity(), R.string.done, Toast.LENGTH_SHORT)
           .show();

      task=null;
    }
  }
}
```

(from Threads/AsyncTask/app/src/main/java/com/commonsware/android/async/AsyncDemoFragment.java)

This is another variation on the *lorem ipsum* list of words, used frequently throughout this book. This time, rather than simply hand the list of words to an `ArrayAdapter`, we simulate having to work to create these words in the background using `AddStringTask`, our `AsyncTask` implementation.

In `onCreate()`, we call `setRetainInstance(true)`, so Android will retain this fragment across configuration changes, such as a screen rotation. Since our fragment is being newly created, we initialize our `model` to be an `ArrayList` of `String` values, plus kick off our `AsyncTask` (the `AddStringTask` inner class, described below), saving the `AddStringTask` in a `task` data member. Then, in `onViewCreated()`, we set up the adapter and attach it to the `ListView`, also preventing the `ListView` scrollbars from fading away as is their norm.

In the declaration of `AddStringTask`, we use the generics to set up the specific types of data we are going to leverage. Specifically:

1. We do not need any configuration information in this case, so our first type is `Void`
2. We want to pass each string "generated" by our background task to `onProgressUpdate()`, so we can add it to our list, so our second type is `String`
3. We do not have any results, strictly speaking (beyond the updates), so our third type is `Void`

The `doInBackground()` method is invoked in a background thread. Hence, we can take as long as we like. In a production application, we would be, perhaps, iterating over a list of URLs and downloading each. Here, we iterate over our static list of *lorem ipsum* words, call `publishProgress()` for each, and then sleep 400 milliseconds to simulate real work being done. We also call `isCancelled()` on each pass, to see if our task has been cancelled, skipping the work if it has so we can clean up this background thread.

Since we elected to have no configuration information, we should not need parameters to `doInBackground()`. However, the contract with `AsyncTask` says we need to accept a varargs of the first data type, which is why our method parameter is `Void...`.

Since we elected to have no results, we should not need to return anything. Again, though, the contract with `AsyncTask` says we have to return an object of the third data type. Since that data type is `Void`, our returned object is `null`.

The `onProgressUpdate()` method is called on the UI thread, and we want to do something to let the user know we are progressing on loading up these strings. In this case, we simply add the string to the `ArrayAdapter`, so it gets appended to the end of the list. However, we only do this if we have not already been canceled.

The `onProgressUpdate()` method receives a `String...` varargs because that is the second data type in our class declaration. Since we are only passing one string per call to `publishProgress()`, we only need to examine the first entry in the varargs array.

The `onPostExecute()` method is called on the UI thread, and we want to do something to indicate that the background work is complete. In a real system, there may be some `ProgressBar` to dismiss or some animation to stop. Here, we simply raise a `Toast` and set `task` to `null`. We do not need to worry about calling `isCancelled()`, because `onPostExecute()` will not be invoked if our task has been cancelled.

Since we elected to have no results, we should not need any parameters. The contract with `AsyncTask` says we have to accept a single value of the third data type. Since that data type is `Void`, our method parameter is `Void unused`.

To use `AddStringTask`, we simply create an instance and call `execute()` on it. That starts the chain of events eventually leading to the background thread doing its work.

If `AddStringTask` required configuration parameters, we would have not used `Void` as our first data type, and the constructor would accept zero or more parameters of the defined type. Those values would eventually be passed to `doInBackground()`.

Our fragment also has an `onDestroy()` method that calls `cancel()` on the `AsyncTask` if it is still outstanding (`task` is not `null`). This work of cancelling the task and checking to see if the task is cancelled exists for two reasons:

1. Efficiency, as we should skip any serious work that is not needed if our task itself is not needed
2. To avoid a crash if we attempt to raise a `Toast` on a destroyed activity, such as the user launching the activity, then pressing BACK before we complete the background work and display the `Toast`

The Activity and the Results

`AsyncDemo` is an `Activity` with the standard recipe for kicking off an instance of a dynamic fragment:

```
package com.commonsware.android.async;

import android.support.v4.app.FragmentActivity;
```

```
import android.os.Bundle;

public class AsyncDemo extends FragmentActivity {
  @Override
  public void onCreate(Bundle savedInstanceState) {
    super.onCreate(savedInstanceState);

    if (getSupportFragmentManager().findFragmentById(android.R.id.content) == null) {
      getSupportFragmentManager().beginTransaction()
                          .add(android.R.id.content,
                               new AsyncDemoFragment()).commit();
    }
  }
}
```

(from Threads/AsyncTask/app/src/main/java/com/commonsware/android/async/AsyncDemo.java)

If you build, install, and run this project, you will see the list being populated in "real time" over a few seconds, followed by a `Toast` indicating completion.

Threads and Configuration Changes

One problem with the default destroy-and-create cycle that activities go through on a configuration change comes from background threads. If the activity has started some background work — through an `AsyncTask`, for example – and then the activity is destroyed and re-created, somehow the `AsyncTask` needs to know about this. Otherwise, the `AsyncTask` might well send updates and final results to the *old* activity, with the new activity none the wiser. In fact, the new activity might start up the background work *again*, wasting resources.

That is why, in the sample above, we are retaining the fragment instance. The fragment instance holds onto its data model (in this case, the `ArrayList` of Latin words) and knows not to kick off a new `AsyncTask` just because the configuration changed. Moreover, we retain that data model, so the new `ListView` created due to the configuration change can work with a new adapter backed by the old data model, so we do not lose our existing set of Latin words.

We also have to be very careful not to try referring to the activity (via `getActivity()` on the fragment) from our background thread (`doInBackground()`). Because, suppose that during the middle of the `doInBackground()` processing, the user rotates the screen. The activity we work with will change on the fly, on the main application thread, independently of the work being done in the background. The activity returned by `getActivity()` may not be in a useful state for us while this configuration change is going on.

However, it is safe for us to use `getActivity()` from `onPostExecute()`, and even from `onProgressUpdate()`. For those callbacks, either the configuration change has not yet happened, or it has been completed — we will not be in the middle of the change.

Where Not to Use AsyncTask

`AsyncTask`, particularly in conjunction with a dynamic fragment, is a wonderful solution for most needs for a background thread.

The key word in that sentence is "most".

`AsyncTask` manages a thread pool, from which it pulls the threads to be used by task instances. Thread pools assume that they will get their threads back after a reasonable period of time. Hence, `AsyncTask` is a poor choice when you do not know how long you need the thread (e.g., thread listening on a socket for a chat client, where you need the thread until the user exits the client).

About the AsyncTask Thread Pool

Moreover, the thread pool that `AsyncTask` manages has varied in size.

In Android 1.5, it was a single thread.

In Android 1.6, it was expanded to support many parallel threads, probably more than you will ever need.

In Android 3.2, it has shrunk back to a single thread, if your `android:targetSdkVersion` is set to 13 or higher. This was to address concerns about:

- Forking too many threads and starving the CPU
- Developers thinking that there is an ordering dependency between forked tasks, when with the parallel execution there is none

If you wish, starting with API Level 11, you can supply your own `Executor` (from the `java.util.concurrent` package) that has whatever thread pool you wish, so you can manage this more yourself. In addition to the serialized, one-at-a-time `Executor`, there is a built-in `Executor` that implements the old thread pool, that you can use rather than rolling your own.

If your `minSdkVersion` is 11 or higher, use `executeOnExecutor(AsyncTask.THREAD_POOL_EXECUTOR)` if you specifically want to opt into a multi-thread thread pool. If your `minSdkVersion` is below 11, you will still want to do that... but only on API Level 11+ devices, falling back to `execute()` on the older devices. This static utility method handles this for you:

```
@TargetApi(Build.VERSION_CODES.HONEYCOMB)
static public <T> void executeAsyncTask(AsyncTask<T, ?, ?> task,
                                        T... params) {
  if (Build.VERSION.SDK_INT >= Build.VERSION_CODES.HONEYCOMB) {
    task.executeOnExecutor(AsyncTask.THREAD_POOL_EXECUTOR, params);
  }
  else {
    task.execute(params);
  }
}
```

To use this, call `executeAsyncTask()`, passing in your `AsyncTask` instance and the parameters you would ordinarily have passed to `execute()`.

An explanation of what we are doing here, in terms of the `@TargetApi` annotation and such, will come later in the book.

Also note that the number of threads in the multiple-thread thread pool has *also* changed over the years. Originally, that pool could climb to as many as 128 threads, which was far too many. As of Android 4.4, the thread pool will only grow to "the number of CPU cores * 2 + 1", so on a dual-core device, the thread pool will cap at 5 threads. Further tasks will be queued, up to a maximum of 128 queued tasks.

Alternatives to AsyncTask

There are other ways of handling background threads without using `AsyncTask`:

- You can employ a `Handler`, which has a `handleMessage()` method that will process `Message` objects, dispatched from a background thread, on the main application thread
- You can supply a `Runnable` to be executed on the main application thread to `post()` on any `View`, or to `runOnUiThread()` on `Activity`
- You can supply a `Runnable`, plus a delay period in milliseconds, to `postDelayed()` on any `View`, to run the `Runnable` on the main application thread after *at least* that number of millisecond has elapsed

Of these, the `Runnable` options are the easiest to use.

These can also be used to allow the main application thread to postpone work, to be done *later* on the main application thread. For example, you can use `postDelayed()` to set up a lightweight polling "loop" within an activity, without needing the overhead of an extra thread, such as the one created by `Timer` and `TimerTask`. To see how this works, let's take a peek at the `Threads/PostDelayed` sample project.

This project contains a single activity, named `PostDelayedDemo`:

```
package com.commonsware.android.post;

import android.app.Activity;
import android.os.Bundle;
import android.view.View;
import android.widget.Toast;

public class PostDelayedDemo extends Activity implements Runnable {
  private static final int PERIOD=5000;
  private View root=null;

  @Override
  protected void onCreate(Bundle savedInstanceState) {
    super.onCreate(savedInstanceState);
    setContentView(R.layout.main);
    root=findViewById(android.R.id.content);
  }

  @Override
  public void onStart() {
    super.onStart();

    run();
  }

  @Override
  public void onStop() {
    root.removeCallbacks(this);

    super.onStop();
  }

  @Override
  public void run() {
    Toast.makeText(PostDelayedDemo.this, "Who-hoo!", Toast.LENGTH_SHORT)
         .show();
```

```
    root.postDelayed(this, PERIOD);
  }
}
```

(from Threads/PostDelayed/app/src/main/java/com/commonsware/android/post/PostDelayedDemo.java)

We want to display a `Toast` every five seconds. To do this, in `onCreate()`, we get our hands on the container for an activity's UI, known as `android.R.id.content`, via `findViewById()`. Then, in `onStart()`, we call a `run()` method on our activity, which displays the `Toast` and calls `postDelayed()` to schedule *itself* (as an implementation of `Runnable`) to be run again in `PERIOD` milliseconds. While our activity is in the foreground, the `Toast` will appear every `PERIOD` milliseconds as a result. Once something else comes to the foreground — such as by the user pressing BACK — our `onStop()` method is called, where we call `removeCallbacks()` to "undo" the `postDelayed()` call.

And Now, The Caveats

Background threads, while eminently possible using `AsyncTask` and kin, are not all happiness and warm puppies. Background threads not only add complexity, but they have real-world costs in terms of available memory, CPU, and battery life.

To that end, there is a wide range of scenarios you need to account for with your background thread, including:

1. The possibility that users will interact with your activity's UI while the background thread is chugging along. If the work that the background thread is doing is altered or invalidated by the user input, you will need to communicate this to the background thread. Android includes many classes in the `java.util.concurrent` package that will help you communicate safely with your background thread.
2. The possibility that the process will be terminated while your work is still going on. This is why in many cases, rather than use an `AsyncTask` or a bare `Thread`, you will wind up using a `Service`, such as an `IntentService`. This will be explored in greater detail later in this book.
3. The possibility that your user will get irritated if you chew up a lot of CPU time and battery life without giving any payback. Tactically, this means using `ProgressBar` or other means of letting the user know that something is happening. Strategically, this means you still need to be efficient at what you do — background threads are no panacea for sluggish or pointless code.

4. The possibility that you will encounter an error during background processing. For example, if you are gathering information off the Internet, the device might lose connectivity. Alerting the user of the problem via a `Notification` and shutting down the background thread may be your best option.

Event Buses

Event-driven programming has been around for nearly a quarter-century. Much of Android's UI model is event-driven, where we find out about these events via callbacks (e.g., `onCreate()` for the "start an activity" event) and registered listeners (e.g., `OnClickListener` for when the user taps on a widget).

However, originally, Android did not have a very fine-grained event or message bus implementation that we as developers could use. The `Intent` system works like a message bus, but it is aimed at inter-process communication (IPC) as much as in-process communication, and that comes with some costs.

However, over time, particularly starting in 2012, event buses started to pop up, and these are very useful for organizing communication within your Android application and across threads. Used properly, an event bus can eliminate the need for `AsyncTask` and the other solutions for communicating back to the main application thread, while simultaneously helping you logically decouple independent pieces of your code.

What Is an Event Bus?

Whether you consider it an "event bus" (or "message bus"), the "publisher/subscriber" (or "pub/sub") pattern, or a subset of the "observer" pattern, the programming model where components produce events that others consume is reasonably common in modern software development.

An event bus is designed to decouple the sources of events from the consumers of those events. Or, as one event bus author put it:

> I want an easy, centralized way to notify code that's interested in specific types of events when those events occur without any direct coupling between the code the publishes [sic] an event and the code that receives it.

With the traditional Java listener or observer pattern implementation, the component producing an event needs direct access to consumers of that event. Sometimes, that list of consumers is limited to a single consumer, as with many event handlers associated with Android widgets (e.g., just one `OnClickListener`). But this source-holds-the-sinks coding pattern limits flexibility, as it requires explicit registration by consumers with producers of events, and it may not be that easy for the consumer to *reach* the producer. Furthermore, such direct connections are considered to be a relatively strong coupling between those components, and often times our objective is to have looser coupling.

An event bus provides a standard communications channel (or "bus") that event producers and event consumers can hook into. Event producers merely need to hand the event to the bus; the bus will handle directing those events to relevant consumers. This reduces the coupling between the producers and consumers, sometimes even reducing the amount of code needed to source and sink these events.

OK, But Why Are We Bothering With This?

Later on, we are going to have components other than our activities. In particular, we will have services, which are designed to run briefly in the background to perform some operation. Just as communications between activities tends to be loosely coupled, so too are communications between activities and services. An event bus is a great way for the service to let other pieces of the app know that certain work was done (e.g., "the download is complete, so update the UI").

In the short term, we will use an event bus to have a model fragment let the app know that some data was loaded. In the tutorials, "some data" will be the book contents; in the sample app illustrated in this chapter, "some data" will be some Latin words.

Introducing greenrobot's EventBus

The event bus implementation that we will be using in the tutorials is greenrobot's EventBus, an open source implementation based on the Guava project's event bus. With greenrobot's EventBus, it is fairly easy to send a message from one part of your app to another disparate part of your app.

To illustrate its use, take a look at the `EventBus/AsyncDemo3` sample project. This is a reworking of a previous example that used an `AsyncTask` to pretend to download our

list of Latin words, populating a `ListView` with those words as they arrive. This sample replaces the `AsyncTask` with a model fragment that will keep track of the words and a background thread that will "download" the words. We will use events raised by the model fragment to let the UI fragment know words as they arrive.

Requesting the Artifact

greenrobot's EventBus is distributed as an artifact that you can integrate in your project via the `dependencies` in your module's `build.gradle` file:

```
apply plugin: 'com.android.application'

dependencies {
    implementation 'org.greenrobot:eventbus:3.0.0'
}

android {
    compileSdkVersion 19
    buildToolsVersion '26.0.2'

  defaultConfig {
    targetSdkVersion 17
    applicationId "com.commonsware.android.eventbus.greenrobot3"
  }
}
```

(from EventBus/AsyncDemo3/app/build.gradle)

Defining Events

With greenrobot's EventBus, the "events" are objects of arbitrary classes that you define. Each different class represents a different type of event, and you can define as many different event classes as you wish. Those classes do not need to inherit from any special base class, or implement some special interface, or have any magic annotations. They are just classes.

You may wish to put data members, constructors, and accessor methods on the event classes, for any data you wish to pass around specific to the event itself. A `SearchEvent`, for example, might include the search query string as part of the event object.

In our case, we have a `WordReadyEvent` that contains the new word:

```
package com.commonsware.android.eventbus;

class WordReadyEvent {
  private String word;

  WordReadyEvent(String word) {
    this.word=word;
  }

  String getWord() {
    return(word);
  }
}
```

(from EventBus/AsyncDemo3/app/src/main/java/com/commonsware/android/eventbus/WordReadyEvent.java)

Posting Events

To post an event, all you need to do is obtain an instance of an `EventBus` – typically via the `getDefault()` method on `EventBus` — and call `post()` on it, passing in the event to be delivered to any interested party within your app.

With that in mind, let's look at the `ModelFragment` that will be loading in our words:

```
package com.commonsware.android.eventbus;

import android.app.Fragment;
import android.os.Bundle;
import android.os.SystemClock;
import org.greenrobot.eventbus.EventBus;
import java.util.ArrayList;
import java.util.Collections;
import java.util.List;

public class ModelFragment extends Fragment {
  private static final String[] items= { "lorem", "ipsum", "dolor",
      "sit", "amet", "consectetuer", "adipiscing", "elit", "morbi",
      "vel", "ligula", "vitae", "arcu", "aliquet", "mollis", "etiam",
      "vel", "erat", "placerat", "ante", "porttitor", "sodales",
      "pellentesque", "augue", "purus" };
  private List<String> model=
    Collections.synchronizedList(new ArrayList<String>());
  private boolean isStarted=false;

  @Override
  public void onCreate(Bundle savedInstanceState) {
```

```
    super.onCreate(savedInstanceState);

    setRetainInstance(true);

    if (!isStarted) {
      isStarted=true;
      new LoadWordsThread().start();
    }
  }

  public ArrayList<String> getModel() {
    return(new ArrayList<String>(model));
  }

  class LoadWordsThread extends Thread {
    @Override
    public void run() {
      for (String item : items) {
        if (!isInterrupted()) {
          model.add(item);
          EventBus.getDefault().post(new WordReadyEvent(item));
          SystemClock.sleep(400);
        }
      }
    }
  }
}
```

(from EventBus/AsyncDemo3/app/src/main/java/com/commonsware/android/eventbus/ModelFragment.java)

This fragment has no UI — it exists solely to manage a data model on behalf of the rest of the hosting activity. Hence, there is no `onCreateView()` or any other UI logic directly in this fragment.

In `onCreate()`, we call `setRetainInstance(true)`, so that if the user rotates the screen or otherwise triggers a configuration change, our model fragment will survive the change and be attached to the new activity instance. Then, if we have not already started the `LoadWordsThread`, we do so. `LoadWordsThread` iterates over our list of words, sleeps for 400ms to simulate doing real work, adds each word to an `ArrayList` of words that it manages... and calls `post()` to raise a `WordReadyEvent` to let something else know that the model has changed.

Receiving Events

To receive posted events, you need to do three things:

1. Call `register()` on the `EventBus` to tell it that you have an object that wants to receive events
2. Call `unregister()` on the `EventBus` to tell it to stop delivering events to a previously-registered object
3. Implement methods annotated with `@Subscribe` to indicate the type of event you want to receive and to actually process those events

This sample app has an `AsyncDemoFragment` that performs those three steps:

```
package com.commonsware.android.eventbus;

import android.app.Activity;
import android.app.ListFragment;
import android.os.Bundle;
import android.view.View;
import android.widget.ArrayAdapter;
import org.greenrobot.eventbus.EventBus;
import org.greenrobot.eventbus.Subscribe;
import org.greenrobot.eventbus.ThreadMode;
import java.util.ArrayList;

public class AsyncDemoFragment extends ListFragment {
  private ArrayAdapter<String> adapter=null;
  private ArrayList<String> model=null;

  @Override
  public void onViewCreated(View view, Bundle savedInstanceState) {
    adapter=
        new ArrayAdapter<String>(getActivity(),
                                 android.R.layout.simple_list_item_1,
                                 model);

    getListView().setScrollbarFadingEnabled(false);
    setListAdapter(adapter);
  }

  @Override
  public void onAttach(Activity activity) {
    super.onAttach(activity);

    EventBus.getDefault().register(this);
  }

  @Override
  public void onDetach() {
    EventBus.getDefault().unregister(this);
```

```
    super.onDetach();
  }

  @Subscribe(threadMode = ThreadMode.MAIN)
  public void onWordReady(WordReadyEvent event) {
    adapter.add(event.getWord());
  }

  public void setModel(ArrayList<String> model) {
    this.model=model;
  }
}
```

(from EventBus/AsyncDemo3/app/src/main/java/com/commonsware/android/eventbus/AsyncDemoFragment.java)

The fragment starts by overriding `onViewCreated()`, where we create an `ArrayAdapter` and use that to populate the `ListView`.

The `onAttach()` and `onDetach()` methods are where we indicate to the `EventBus` that this fragment object wants to receive relevant posted events. `onAttach()` calls `register()`; `onDetach()` calls `unregister()`.

The `onWordReady()` method, via its parameter and `@Subscribe` annotation, indicates that we are interested in `WordReadyEvents` as they are raised. Our `onWordReady()` method will be called for each `WordReadyEvent` passed to `post()` on the `EventBus`. Since the `@Subscribe` annotation has `threadMode = ThreadMode.MAIN` as part of its configuration, `onWordReady()` will be called on the main application thread, so it is safe for us to update our UI. greenrobot's EventBus is responsible for getting this event to the main application thread — note that we are posting the event from the `LoadWordsThread`, which is a background thread.

In `onWordReady()`, we get the newly-added word, which we can add to our `ArrayAdapter`. `add()` on `ArrayAdapter` appends the word to the end of the list and informs the attached `ListView` that the data changed, so the `ListView` can redraw itself.

What is not obvious, though, from the code in this class is how we are getting the `model` that we are using in `onViewCreated()`. `AsyncDemoFragment` has its own `ArrayList` of words, set via the `setModel()` method. Our `ArrayAdapter` is wrapped around this model. But the master copy of the words is being held by the `ModelFragment`. If the `ModelFragment` has the model, and the `AsyncDemoFragment` needs the model, how are the two being connected?

The Activity

That is handled by our hosting activity, as it sets up these two fragments:

```
package com.commonsware.android.eventbus;

import android.app.Activity;
import android.app.FragmentManager;
import android.app.FragmentTransaction;
import android.os.Bundle;

public class AsyncDemo extends Activity {
  private static final String MODEL_TAG="model";
  private ModelFragment mFrag=null;

  @Override
  public void onCreate(Bundle savedInstanceState) {
    super.onCreate(savedInstanceState);

    FragmentManager mgr=getFragmentManager();
    FragmentTransaction trans=mgr.beginTransaction();

    mFrag=(ModelFragment)mgr.findFragmentByTag(MODEL_TAG);

    if (mFrag == null) {
      mFrag=new ModelFragment();
      trans.add(mFrag, MODEL_TAG);
    }

    AsyncDemoFragment demo=
        (AsyncDemoFragment)mgr.findFragmentById(android.R.id.content);

    if (demo == null) {
      demo=new AsyncDemoFragment();
      trans.add(android.R.id.content, demo);
    }

    demo.setModel(mFrag.getModel());

    if (!trans.isEmpty()) {
      trans.commit();
    }
  }
}
```

(from EventBus/AsyncDemo3/app/src/main/java/com/commonsware/android/eventbus/AsyncDemo.java)

In `onCreate()`, we first see if we already have an instance of our model fragment, held by the `FragmentManager` under a `MODEL_TAG` tag. If not, we create an instance of the `ModelFragment` and add it to the `FragmentManager`, under that tag, via a `FragmentTransaction`.

We then see if we already have an instance of our `AsyncDemoFragment`. If not, we create one and add it to the `FragmentManager`, pouring its UI into `android.R.id.content`, via another `FragmentTransaction`.

Then, we connect the two, calling `getModel()` on the `ModelFragment` and handing the result to `setModel()` on the `AsyncDemoFragment`.

When our activity is newly launched, neither fragment exists. Both fragments are created, and the `AsyncDemoFragment` gets its model array from the `ModelFragment`. That array is initially empty. As the `ModelFragment` adds elements to the array, it posts the `WordReadyEvent`, which triggers the `AsyncDemoFragment` to tell the `ArrayAdapter` and `ListView` that the model data changed.

If we undergo a configuration change, the `ModelFragment` is retained, but the `AsyncDemoFragment` is not. Hence, the activity will always be creating an `AsyncDemoFragment`. But the model we give to the `AsyncDemoFragment` may already have words in it, and those words will appear immediately when the `ArrayAdapter` is wrapped around the model. If the `LoadWordsThread` is still running, the new `AsyncDemoFragment` will pick up any new `WordReadyEvents` that are raised, triggering it to update the `ListView` as before.

Visit the Trails!

We will cover much more about jank, and how to detect and diagnose it, in a later chapter.

There are many more features in the greenrobot EventBus implementation. We will see some of those, plus other event bus implementations, in a later chapter on event bus alternatives.

Requesting Permissions

In the late 1990's, a wave of viruses spread through the Internet, delivered via email, using contact information culled from Microsoft Outlook. A virus would simply email copies of itself to each of the Outlook contacts that had an email address. This was possible because, at the time, Outlook did not take any steps to protect data from programs using the Outlook API, since that API was designed for ordinary developers, not virus authors.

Nowadays, many applications that hold onto contact data secure that data by requiring that a user explicitly grant rights for other programs to access the contact information. Those rights could be granted on a case-by-case basis or all at once at install time.

Android is no different, in that it requires permissions for applications to read or write contact data. Android's permission system is useful well beyond contact data, and for content providers and services beyond those supplied by the Android framework.

You, as an Android developer, will frequently need to ensure your applications have the appropriate permissions to do what you want to do with other applications' data. This chapter covers this topic, both the classic approach used for all permissions prior to Android 6.0 and the new runtime permission system used for certain permissions in Android 6.0+.

You may also elect to require permissions for other applications to use your data or services, if you make those available to other Android components. This will be discussed later in this book.

Frequently-Asked Questions About Permissions

Permissions are occasionally a confusing topic in Android app development, more so now that Android 6.0 has arrived and has changed the permission system a fair bit. Here are some common questions about permissions to help get us started.

What Is a Permission?

A permission is a way for Android (or, sometimes, a third-party app) to require an app developer to notify the user about something that the app will do that might raise concerns with the user. Only if an app holds a certain permission can the app do certain things that are defended by that permission.

Mechanically, permissions take the form of elements in the manifest. Right now, we are focusing on requesting and holding permissions, and so we will be working with the `<uses-permission>` element.

When Will I Need a Permission?

Most permissions that you will deal with come from Android itself. Usually, the documentation will tell you when you need to request and hold one of these permissions.

However, occasionally the documentation has gaps.

If you are trying out some code and you crash with a `SecurityException` the description of the exception may tell you that you need to hold a certain permission — that means you need to add the corresponding `<uses-permission>` element to your manifest.

Third-party code, including Google's own Play Services SDK, may define their own custom permissions. Once again, ideally, you find out that you need to request a permission through documentation, and otherwise you find out through crashing during testing.

What Are Some Common Permissions, and What Do They Defend?

There are dozens upon dozens of permissions in Android. Here are some of the permissions we will see in this book:

- `INTERNET`, if your application wishes to access the Internet through any means from your own process, using anything from raw Java sockets through the `WebView` widget
- `WRITE_EXTERNAL_STORAGE`, for writing data to external storage
- `ACCESS_COARSE_LOCATION` and `ACCESS_FINE_LOCATION`, for determining where the device is
- `READ_CONTACTS`, to get at personally-identifying information of arbitrary contacts that the user has in their Contacts app

In this book and in casual conversation, we refer to the permissions using the unique portion of their name (e.g., `INTERNET`). Really, the full name of the permission will usually have `android.permission.` as a prefix (e.g., `android.permission.INTERNET`), for Android-defined permissions. Custom permissions from third-party apps should use a different prefix. You will need the full permission name, including the prefix, in your manifest entries.

How Do I Request a Permission?

Put a `<uses-permission>` element in your manifest, as a direct child of the root `<manifest>` element (i.e., as a peer element of `<application>`), with an `android:name` attribute identifying the permission that you are interested in.

For example, here is a sample manifest, with a request to hold the `WRITE_EXTERNAL_STORAGE` permission:

```
<?xml version="1.0"?>
<manifest package="com.commonsware.android.fileseditor"
  xmlns:android="http://schemas.android.com/apk/res/android"
  android:versionCode="1"
  android:versionName="1.0">

  <uses-permission android:name="android.permission.WRITE_EXTERNAL_STORAGE" />

  <supports-screens
    android:anyDensity="true"
    android:largeScreens="true"
    android:normalScreens="true"
    android:smallScreens="true" />

  <application
    android:icon="@drawable/ic_launcher"
    android:label="@string/app_name"
    android:theme="@style/Theme.Apptheme">
```

```
    <activity
      android:name=".MainActivity"
      android:label="@string/app_name">
      <intent-filter>
        <action android:name="android.intent.action.MAIN" />

        <category android:name="android.intent.category.LAUNCHER" />
      </intent-filter>
    </activity>
  </application>

</manifest>
```

(from Files/FilesEditor/app/src/main/AndroidManifest.xml)

This is sufficient for most permissions and most devices. Permissions considered to be `dangerous` need special attention on Android 6.0+, and we will cover that in grand detail later in this chapter.

Note that you are welcome to have zero, one, or several such `<uses-permission>` elements. Also note that some libraries that you elect to use might add their own `<uses-permission>` elements to your manifest, through a process called "manifest merger".

When Is the User Informed About These Permissions?

Well, that gets complicated. It depends on the permission, the version of Android the user is using, from where the user is installing the app, and the phase of the moon.

(well, OK, not really that last one)

Installing Through SDK Tools

Anyone who installs an app using Android Studio will not be prompted for permissions. The same holds true for anyone using anything else based on the Android SDK tools — while the app may request permissions, the user is not prompted for them, and the permissions are granted.

(Android 6.0+ and `dangerous` permissions change this up a bit – more on that later in this chapter)

Installing from the Play Store, Android 5.1 and Older

If the user is running an Android 5.1 or older device, and the user goes to install your app from the Play Store, the user will be presented with a roster of permission groups that contain permissions that you are requesting and that are considered to be `dangerous`:

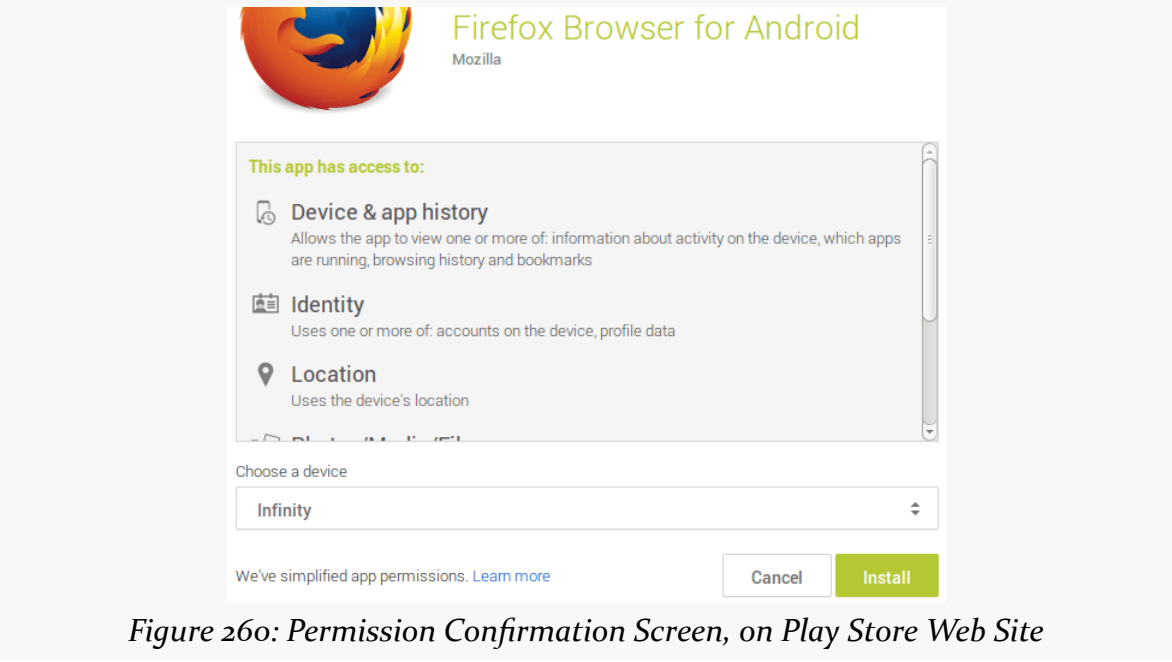

Figure 260: Permission Confirmation Screen, on Play Store Web Site

We will discuss more about permission groups and this `dangerous` concept later in this chapter.

Installing from the Play Store, Android 6.0+

On Android 6.0 and higher, when the user installs your app from the Play Store, what happens depends upon the value of `targetSdkVersion` for your app.

If your `targetSdkVersion` is 22 or lower, you get the same behavior as is described above, where the user sees the list of permission groups which contain permissions that you are requesting and that are considered to be `dangerous`.

If your `targetSdkVersion` is 23 or higher, the user is not prompted about permissions at install time. Instead these prompts will occur when the user runs

your app and when you ask the user for the permissions, as we will see later in this chapter.

Installing by Other Means, Android 5.1 and Older

If you install an app on Android 5.1 or older, by any means (e.g., downloading from a Web site), you will be prompted with a list of all requested permissions:

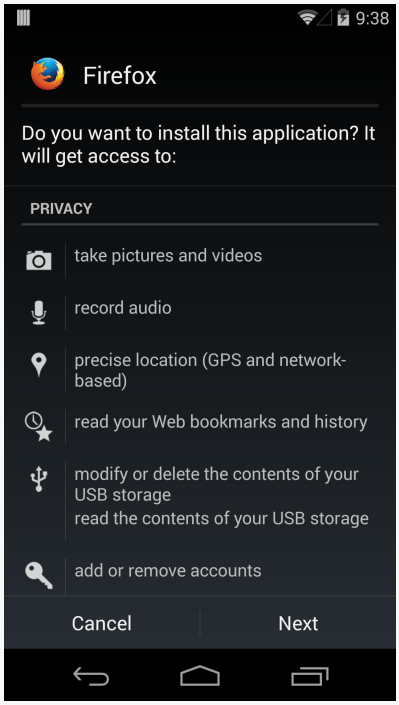

Figure 261: Permission Confirmation Screen, on Android 4.4

Note that this prompt will not appear until you actually have downloaded the app and have begun the installation process. Before then, the device cannot examine the manifest inside the APK file to find the permissions.

Installing by Other Means, Android 6.0+

If your app's `targetSdkVersion` is 23 or higher, and you install the app on an Android 6.0+ device by other means than the Play Store, you will not be prompted about any permissions at install time:

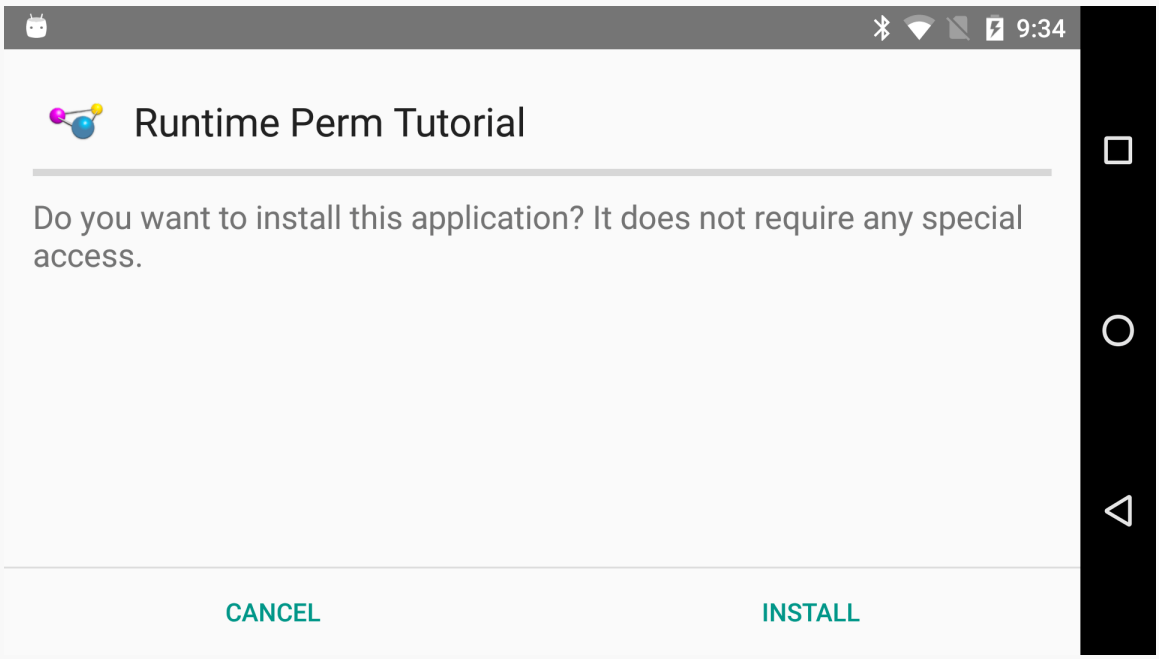

Figure 262: Permission Confirmation Screen, on Android 6.0

Characteristics of Permissions

Several bits of information make up a permission, and some of those affect app developers or users.

Name

We have already seen that permissions have names, and you use them in the `android:name` attribute of the `<uses-permission>` element to identify a permission that you would like your app to hold.

Android framework-defined permissions will begin with `android.permission`. Permissions from libraries or third-party apps will have some other prefix. Make sure that when you create your `<uses-permission>` element that you are using the *fully-qualified* permission name, including `android.permission` or any other prefix.

Also note that Android is case-sensitive, so make sure you use the case of the permission as documented (e.g., `android.permission.INTERNET`). Some versions of Android Studio had a bug where if you let the IDE auto-complete a `<uses-permission>` element for you, sometimes it would have the `android:name`

value appear IN ALL CAPS. This is a bug that has since been fixed, so hopefully it will not affect you in the future.

Protection Level

The definition of a permission, in the framework or in third-party code, will have a "protection level". This describes how the permission itself should be validated. The two protection levels that you will encounter most often are `normal` and `dangerous`.

Normal

A `normal` permission is something that the user *might* care about, but probably not. So, while we need to request the permission in the manifest via `<uses-permission>`, the user will not be bothered about this permission at install time.

The classic example is the `INTERNET` permission. Most Android apps wind up requesting this permission, either for functionality written by the developers or functionality pulled in from libraries (e.g., ad banners). `INTERNET` is considered `normal`, so while we need to request the `INTERNET` permission in the manifest, the user is not informed about this permission anymore at install time.

(the "anymore" note is because in the early days of Android, users were informed about all permissions, regardless of protection level)

Users can see `normal` permissions, though, in other places:

- the list of permissions shown on the Play Store when clicking on a "Permissions" link
- the list of permissions shown in Settings for an app
- third-party tools that help the user understand what capabilities are available to the apps that the user has installed

Dangerous

A `dangerous` permission is one that the definers of the permission (e.g., Google) wants to ensure that the user is aware of and has agreed to.

Classically, this meant that the user would be prompted for this permission at install time. On old versions of Android and the Play Store, `dangerous` permissions would be listed before `normal` permissions.

With Android 6.0+, while `dangerous` permissions are not displayed at install time (for apps with a `targetSdkVersion` of 23 or higher), they will be displayed to the user while the app is running, before the app tries doing something that requires one of those permissions. This is a significant behavior change, so we will be covering it in depth later in this chapter.

Permission Group

Permissions are collected into permission groups.

In the early days of Android, app developers were oblivious to this, as permission groups had no effect on app development, runtime behavior, or user experience.

In the past few years, the "permission" prompts at install time have really been prompting about permission groups. The user is told that the app is requesting permissions from certain groups. Moreover, the blessing that the user gives — by virtue of continuing to install the app — is by *group*, not by permission. If some future update to the app would ask for a new permission, but one from a group that the user agreed to previously, the user would not be informed about this new permission request.

With Android 6.0, permission groups also extend to the runtime permission UX, as while we developers will still request individual permissions, the user will be asked to grant rights with respect to permission groups.

Maximum SDK Version

`<uses-permission>` can have an `android:maxSdkVersion` attribute. This indicates the highest API level for which we need the permission. If the app is running on newer versions of Android, skip the permission.

This is for cases where Android relaxes restrictions over time. We will see an example of this, in the form of the `WRITE_EXTERNAL_STORAGE` permission, in an upcoming chapter.

Minimum SDK Version

You might think that `<uses-permission>` would have an `android:minSdkVersion` attribute to serve as the counterpart to `android:maxSdkVersion`. The `minSdkVersion`

would indicate the lowest API level for which to request a permission; older devices would skip the permission.

Alas, this is not available.

However, there is the awkwardly-named `<uses-permission-sdk-23>` element.

This element functions identically to `<uses-permission>` on Android 6.0+ devices. On older devices, it is ignored.

This element illustrates a problem with the permission system in Android: you have to put all permissions that you want in the manifest. Prior to the runtime permission system in Android 6.0, this would mean that developers who need some controversial permission (e.g., `READ_CONTACTS`) for some fringe feature would need to request the permission from *everyone*, not just those who use the feature. As we will see, the runtime permission system lets us not bother the user until they try using the secured feature. `<uses-permission-sdk-23>` would allow us to not bother with the permission at all on older devices, where its presence might scare away potential users.

New Permissions in Old Applications

Sometimes, Android introduces new permissions that govern behavior that formerly did not require permissions. `WRITE_EXTERNAL_STORAGE` is one example – originally, applications could write to external storage without any permission at all. Android 1.6 introduced `WRITE_EXTERNAL_STORAGE`, required before you can write to external storage. However, applications that were written before Android 1.6 could not possibly request that permission, since it did not exist at the time. Breaking those applications would seem to be a harsh price for progress.

What Android does is "grandfather" in certain permissions for applications supporting earlier SDK versions.

For example, if your `minSdkVersion` is 3 or lower, saying that you support Android 1.5, your application will automatically request `WRITE_EXTERNAL_STORAGE` and `READ_PHONE_STATE`, even if you do not explicitly request those permissions. People installing your application on an Android 1.5 device will see these requests.

Eventually, when you drop support for the older version (e.g., switch to `minSdkVersion` of 4 or higher), Android will no longer automatically request those

permissions. Hence, if your code really *does* need those permissions, you will need to ask for them yourself.

Android 6.0+ Runtime Permission System

In Android 6.0 and higher devices, permissions that are considered to be `dangerous` not only have to be requested via `<uses-permission>` elements, but you *also* have to ask the user to grant you those permissions at runtime. What you gain, though, is that users are not bothered with these permissions at install time, and you can elect to delay asking for certain permissions until such time as the user actually does something that needs them.

This section will occasionally point out snippets of code from the `Permissions/PermissionMonger` sample project.

Let's explore the runtime permissions system via a new series of questions.

What Permissions Are Affected By This?

There are nine permission groups that Android 6.0 manages as user-controllable permissions:

Permission Group	Permission
CALENDAR	READ_CALENDAR, WRITE_CALENDAR
CAMERA	CAMERA
CONTACTS	GET_ACCOUNTS, READ_CONTACTS, WRITE_CONTACTS
LOCATION	ACCESS_COARSE_LOCATION, ACCESS_FINE_LOCATION
MICROPHONE	RECORD_AUDIO
PHONE	ADD_VOICEMAIL, CALL_PHONE, PROCESS_OUTGOING_CALLS, READ_CALL_LOG, READ_PHONE_STATE, USE_SIP, WRITE_CALL_LOG
SENSORS	BODY_SENSORS
SMS	READ_CELL_BROADCASTS, READ_SMS, RECEIVE_SMS, RECEIVE_MMS, RECEIVE_WAP_PUSH, SEND_SMS
STORAGE	READ_EXTERNAL_STORAGE, WRITE_EXTERNAL_STORAGE

Users will be able to revoke permissions by group, through the Settings app. They can go into the page for your app, click on Permissions, and see a list of the permission groups for which you are requesting permissions:

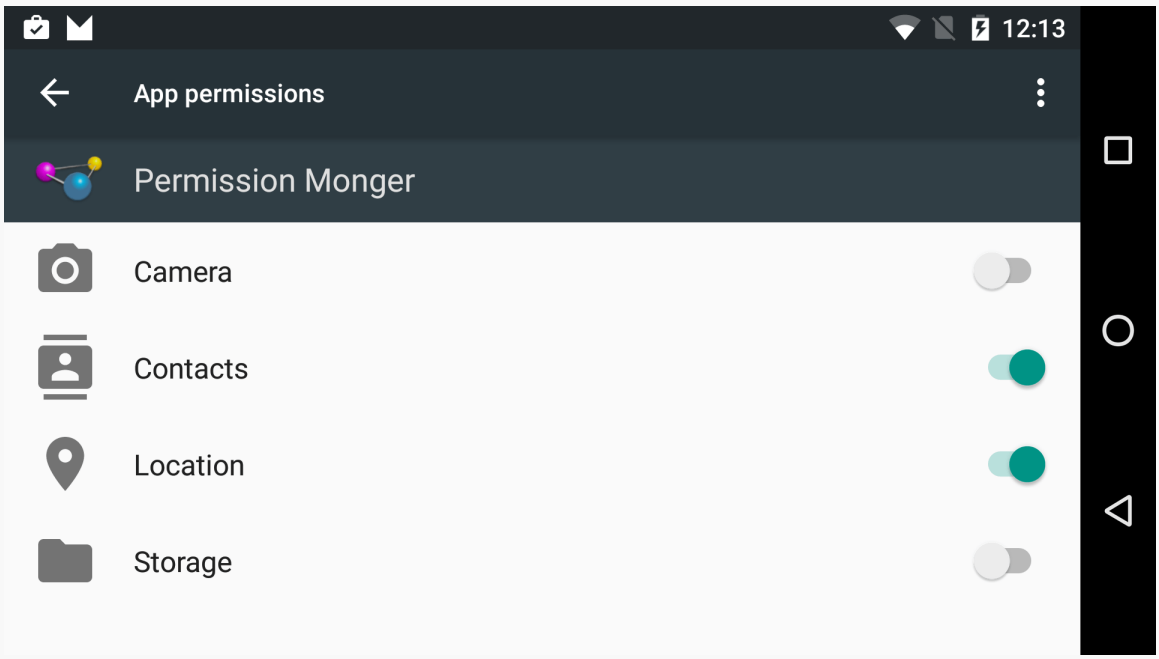

Figure 263: Settings Screen for Permission Monger, Showing Permissions

What Goes in the Manifest?

The same `<uses-permission>` elements as before. These declare the superset of all possible permissions that you can have. If you do not have a `<uses-permission>` element for a particular permission, you cannot ask for it at runtime, and the user cannot grant it to you.

How Do I Know If I Have Permission?

On Android 6.0+, you can call a `checkSelfPermission()` method, available on any `Context` (e.g., your `Activity`). This will return either `PERMISSION_GRANTED` or `PERMISSION_DENIED`, depending on whether or not the user granted you permission or you were automatically given permission (e.g., for `normal` permissions).

For a simpler `boolean` check to see if you have the permission, you could have your own `hasPermission()` method:

```
private boolean hasPermission(String perm) {
  return(PackageManager.PERMISSION_GRANTED==checkSelfPermission(perm));
}
```

(from Permissions/PermissionMonger/app/src/main/java/com/commonsware/android/permmonger/MainActivity.java)

Then you can use that `hasPermission()` call where you need it.

For example, the PermissionMonger app requests five permissions in the manifest:

```
<uses-permission android:name="android.permission.ACCESS_FINE_LOCATION"/>
<uses-permission android:name="android.permission.CAMERA"/>
<uses-permission android:name="android.permission.INTERNET"/>
<uses-permission android:name="android.permission.READ_CONTACTS"/>
<uses-permission android:name="android.permission.WRITE_EXTERNAL_STORAGE"/>
```

(from Permissions/PermissionMonger/app/src/main/AndroidManifest.xml)

The UI is then a table showing the current status of those five permissions:

```
private void updateTable() {
  location.setText(String.valueOf(canAccessLocation()));
  camera.setText(String.valueOf(canAccessCamera()));
  internet.setText(String.valueOf(hasPermission(Manifest.permission.INTERNET)));
  contacts.setText(String.valueOf(canAccessContacts()));
  storage.setText(String.valueOf(hasPermission(Manifest.permission.WRITE_EXTERNAL_STORAGE)));
}

private boolean canAccessLocation() {
  return(hasPermission(Manifest.permission.ACCESS_FINE_LOCATION));
}

private boolean canAccessCamera() {
  return(hasPermission(Manifest.permission.CAMERA));
}

private boolean canAccessContacts() {
  return(hasPermission(Manifest.permission.READ_CONTACTS));
}
```

(from Permissions/PermissionMonger/app/src/main/java/com/commonsware/android/permmonger/MainActivity.java)

At the outset, we only have the one "normal" permission: `INTERNET`:

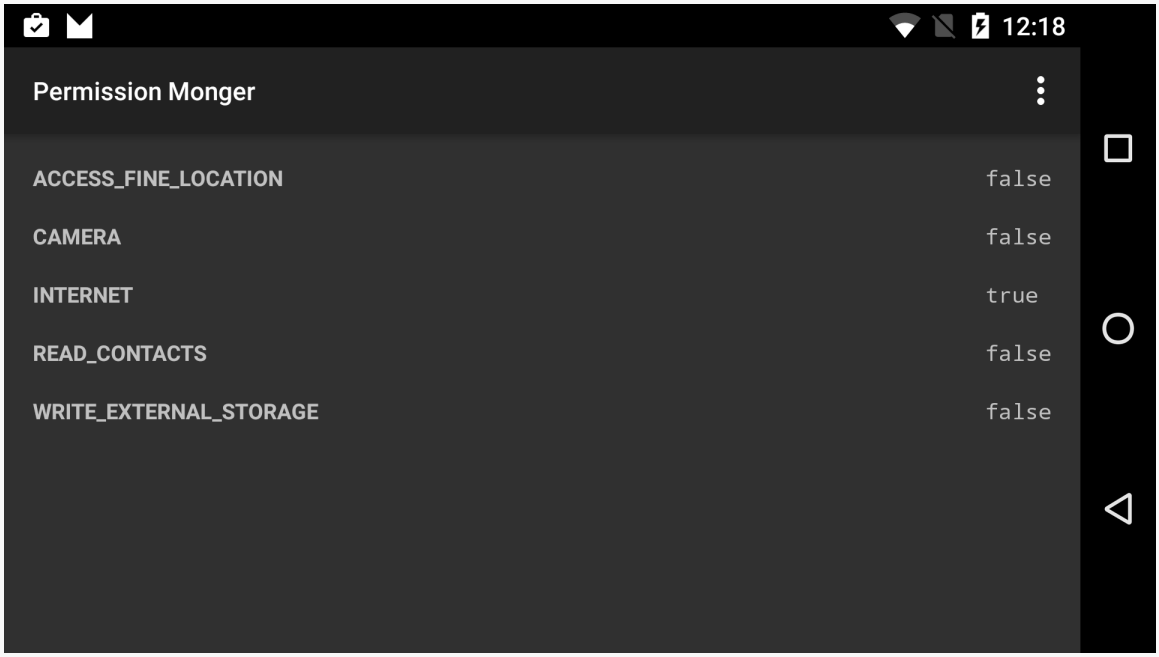

Figure 264: Permission Monger, Showing Initial Permissions

The `checkSelfPermission()` method on `Context` is only available on API Level 23. You can, if you wish, wrap your call to `checkSelfPermission()` in a check of the API level of the device you are running on:

```
if (Build.VERSION.SDK_INT>=Build.VERSION_CODES.M) {
  if (checkSelfPermission(Manifest.permission.WRITE_EXTERNAL_STORAGE)==
    PackageManager.PERMISSION_GRANTED) {
    // do something cool
  }
}
```

A simpler approach is to use `ContextCompat`, from the `support-v4` library. This has a `static` implementation of `checkSelfPermission()` that takes a `Context` and your permission string as parameters. It returns the same value (e.g., `PackageManager.PERMISSION_GRANTED`) as does the `checkSelfPermission()` that ships with Android 6.0. But, if you are running on an older device, it checks the version for you and returns `PackageManager.PERMISSION_GRANTED` for older devices. So, the above code snippet turns into:

```
if (ContextCompat.checkSelfPermission(this,
  Manifest.permission.WRITE_EXTERNAL_STORAGE)==
    PackageManager.PERMISSION_GRANTED) {
```

```
  // do something cool
}
```

(assuming that `this` is a subclass of `Context`, like `Activity`)

How Do I Know If the User Takes Permissions Away From Me?

If the user grants you access to some permission group, the only way the user can revoke that is via the Settings app. If the user *does* revoke access to a permission group, your process is terminated.

Hence, while your code is running, you will have all permissions that you started with, plus any new ones that the user grants on the fly based upon your request. There should be no circumstance where your process is running yet you lose a permission.

That being said, your app is not specifically notified about losing the permission. You should be calling `checkSelfPermission()` to determine what you can and cannot do, at least for every process invocation. And, since the call appears to be reasonably cheap, you should just call it whenever you need to know whether you can perform a particular operation.

Note that usually your app will be in the background, if it is running at all, at the time when a runtime permission is revoked. Particularly in an Android 7.0+ multi-window environment, though, it is possible that you will still be visible when the user revokes a runtime permission. Your process is terminated in any case, and if you were visible, your UI is removed from the screen.

How Do I Ask the User For Permission?

To ask the user for one of the runtime permissions, call `requestPermissions()` on your `Activity`. This takes a `String` array of the permissions that you are requesting and a locally-unique integer to identify this request from any other similar requests that you may be making. This `int` serves in much the same role as does the `int` passed into `startActivityForResult()`, though you should keep the value to 8 bits (`0` to `255`) for maximum compatibility.

For example, PermissionMonger will check in `onCreate()` to see if we can access locations or access contacts, and if not, it will request access to those two permissions:

```
    if (!canAccessLocation() || !canAccessContacts()) {
      requestPermissions(INITIAL_PERMS, INITIAL_REQUEST);
    }
```

(from Permissions/PermissionMonger/app/src/main/java/com/commonsware/android/permmonger/MainActivity.java)

`INITIAL_PERMS` and `INITIAL_REQUEST` are just `static final` data members:

```
  private static final String[] INITIAL_PERMS={
    Manifest.permission.ACCESS_FINE_LOCATION,
    Manifest.permission.READ_CONTACTS
  };
```

(from Permissions/PermissionMonger/app/src/main/java/com/commonsware/android/permmonger/MainActivity.java)

```
  private static final int INITIAL_REQUEST=1337;
```

(from Permissions/PermissionMonger/app/src/main/java/com/commonsware/android/permmonger/MainActivity.java)

When the app is first launched, dialogs will appear, one per permission that you requested, asking the user if they would be so kind as to allow your app to do the things that you requested:

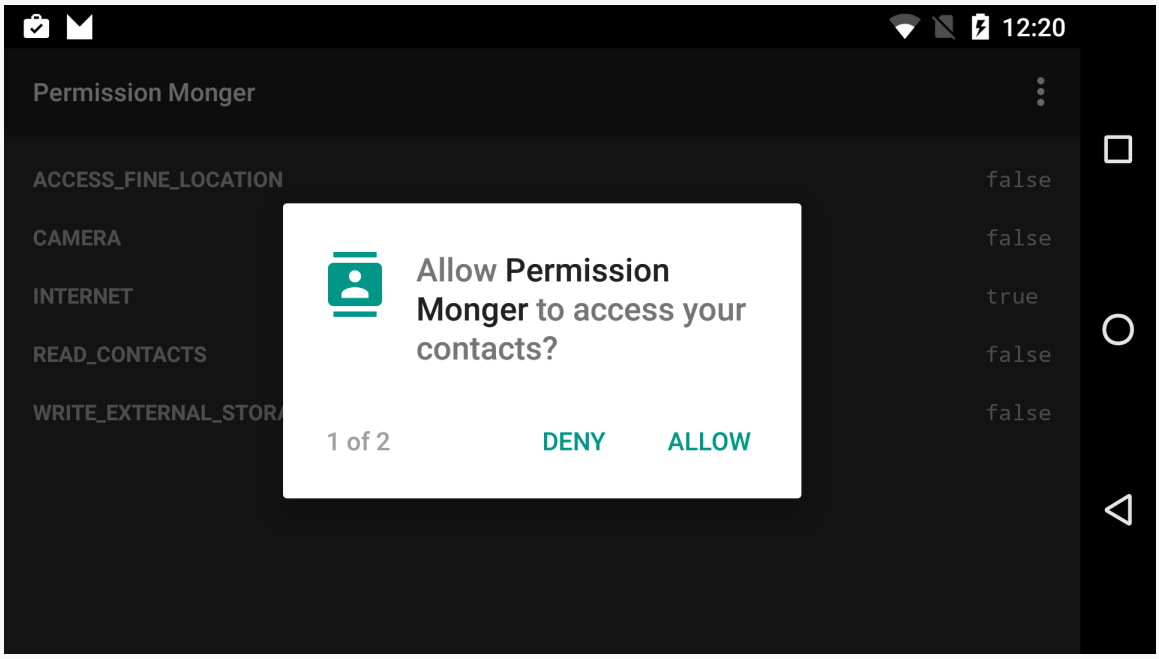

Figure 265: Permission Monger, Requesting READ_CONTACTS Permission

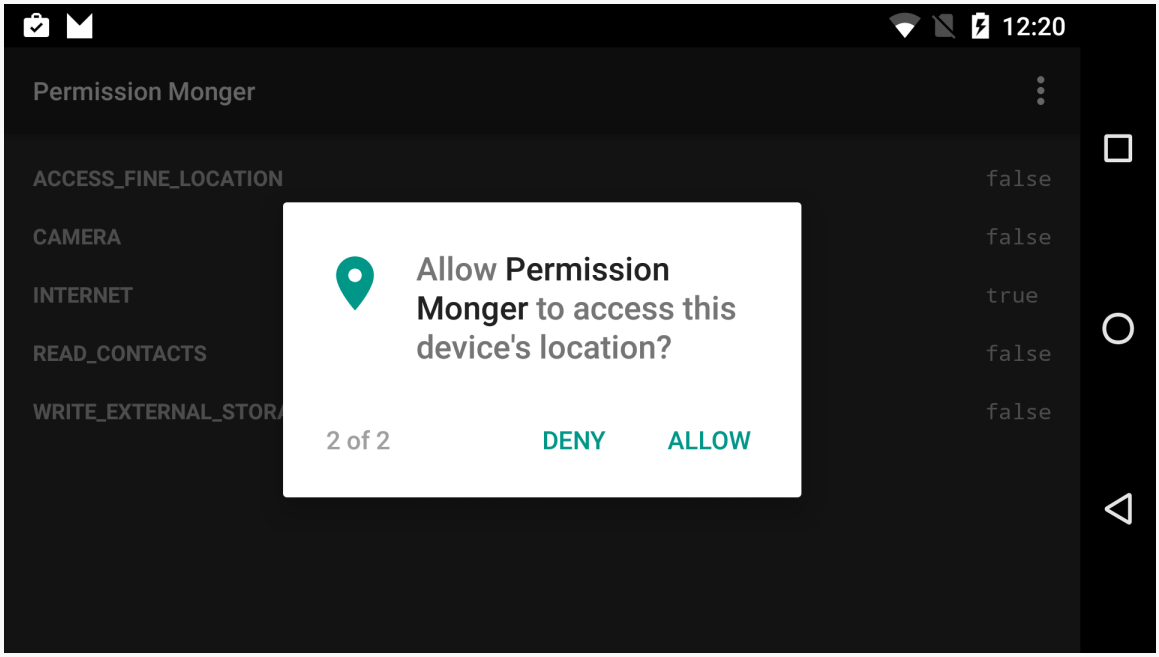

Figure 266: Permission Monger, Requesting ACCESS_FINE_LOCATION Permission

When the user has proceeded through the dialogs, you will be called with `onRequestPermissionsResult()`. You are passed three parameters:

- the locally-unique integer from your `requestPermissions()` call, to identify which `requestPermissions()` call this is the result for
- a `String` array of the requested permissions
- an `int` array of the corresponding results (`PERMISSION_GRANTED` or `PERMISSION_DENIED`)

Whether you use those latter two parameters or simply call `checkSelfPermission()` again is up to you. Regardless, at this point, you should determine what you got, so you know how to react, such as disabling things that the user cannot use given the lack of permission.

Just as `ContextCompat` offers a backwards-compatible implementation of `checkSelfPermission()`, `ActivityCompat` offers a backwards-compatible implementation of `requestPermissions()` that you can use. Otherwise, you will want to take other steps to ensure that you only call `requestPermissions()` on API Level 23+ devices.

When Do I Ask the User For Permission?

That depends a bit on the nature of the permission.

In an ideal world, your app can function without any of the revocable permissions granted to you, albeit perhaps in a limited fashion. In that case, you might ask for permission only when the user tries to do something (e.g., taps on an action bar item) for which you definitely need the permission.

However, sometimes you will need permission to be at all useful to the user. In that case, you will need to ask for permission when the app opens.

In either case, though, bear in mind that while the user will see the dialog asking for permission, the user may not understand *why* you are asking for this permission. You need to make sure that the user understands the cost/benefit trade-off in granting the permission — in other words, what does the user get out of the deal?

For permissions that you are requesting based on user input, you might pop your own dialog or other UI explaining what you want and why you want it, before calling `requestPermissions()`. For permissions that you would want to ask for when the app starts up, make sure that you clearly explain the need for the permissions and what the user gets in exchange as part of a one-time introductory tutorial, one that might also be accessed via an overflow item or nav drawer entry as part of your app's help facility.

When Do I *Not* Ask the User For Permission?

One limitation with the `requestPermissions()` implementation is that it is oblivious to configuration changes.

For example, suppose that in `onCreate()` of your activity, you check to see if you have been granted a runtime permission (via `checkSelfPermission()`), and if you have not, you call `requestPermissions()` to request it from the user. This displays the dialog. Now the user rotates the screen. If the user denies the permission, by default, the user will immediately see the permission dialog again... because your activity will have been destroyed and recreated, and your `onCreate()` will see that you do not have the permission, and so you ask for it again.

In cases like this, you will need to track whether you are in the permission-request flow (e.g., via a `boolean` saved in the instance state `Bundle`) and skip requesting the permission if you have been recreated in the middle of that flow.

What Do I Do If the User Says "No"?

If you were requesting permission as a direct response to some bit of user input (e.g., user tapped on an action bar item), and the user rejects the permission you need to do the work, obviously you cannot do the work. Depending on overall flow, showing a dialog or something to explain why you cannot do what the user asked for may be needed. In some cases, you may deem it to be obvious, by virtue of the fact that the user saw the permission-request dialog and said "deny".

If you were requesting permission pre-emptively, such as when the activity starts, you will need to decide whether that decision needs to be reflected in the current UI (e.g., "no data available" messages, disabled action bar items).

One thing you can do to help here is to detect when this has occurred before you request permissions again. Before you call `requestPermissions()`, you can call `shouldShowRequestPermissionRationale()`, supplying the name of a permission. This will return `true` if the user had previously declined to grant you permission, in cases where Android thinks that the user might benefit from learning a bit more about *why* you need the permission. You can use this to determine whether you should show some explanatory UI of your own first, before continuing with the permission request, or if you should just go ahead and call `requestPermissions()`.

Note that `ActivityCompat` also has a backwards-compatible implementation of `shouldShowRequestPermissionRationale()`, so you can avoid your own API level checks.

What Do I Do If the User Says "No, And Please Stop Asking"?

The second time you ask a user for a particular runtime permission, the user will have a "Never ask again" checkbox:

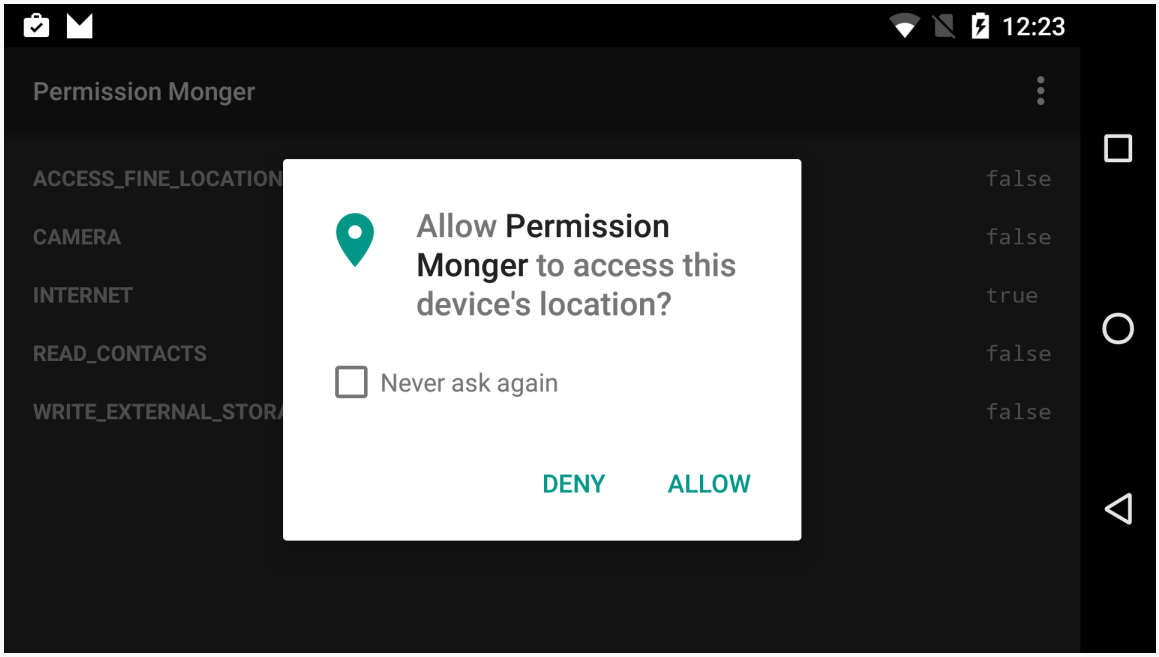

Figure 267: Permission Monger, Requesting ACCESS_FINE_LOCATION Permission (Again)

If the user checks that and clicks the Deny button, not only will you not get the runtime permission now, but all future requests will immediately call `onRequestPermissionsResult()` indicating that your request for permission was denied. The only way the user can now grant you this permission is via the Settings app.

You need to handle this situation with grace and aplomb.

Choices include:

- Disabling UI input (e.g., action bar items) that cannot be performed because you lack permission
- Display a dialog, explaining the situation, with a button that links the user over to your app's screen in Settings, so the user can grant you this permission
- Displaying inline messages about why you cannot show data (e.g., a list of contacts that you cannot show because the user did not grant you access), perhaps with a hyperlink that displays a screen with additional information about the situation

For permissions that, when denied, leave your app in a completely useless state, you may wind up just displaying a screen on app startup that says "sorry, but this app is useless to you", with options for the user to uninstall the app or grant you the desired permissions.

Note that `shouldShowRequestPermissionRationale()` returns `false` if the user declined the permission and checked the checkbox to ask you to stop pestering the user.

What Happens When I Ship This to an Older Device?

Older devices behave as they always have. Since you still list the permissions in the manifest, those permissions will be granted to you if the user installs the app, and the user will be notified about those permissions as part of the installation process. If you are checking the API level yourself, or you are using `ContextCompat` and `ActivityCompat` as described above, your code should just work.

What Happens When My App Has a Lower Target SDK Version?

Apps with a `targetSdkVersion` below 23, on the surface, behave on Android 6.0+ as they would on an older device: the user is prompted for all permissions, and the app is granted those permissions if the app is installed.

However, the user will *still* be able to go into Settings and revoke permissions from these apps, for any permissions the app requests that are in one of the runtime permission groups.

Generally, you will wind up ignoring the issue. All your calls to methods protected by permissions that the user revoke will still "work", insofar as they will not throw a `SecurityException`. However, you just will not get any results back or have the intended effects. So, for example, if you try to `query()` the `ContactsContract` `ContentProvider`, and the user revoked your access to contact-related permissions, the `query()` will return an empty `Cursor`. This is a completely valid response, even ignoring the permission issue, as it is entirely possible that the user has no contacts. Your app should be handling these cases gracefully anyway. Hence, in theory, even if you do nothing special regarding the lost permissions, your app should survive, albeit with reduced functionality for the user. Dave Smith outlines the expected results for legacy apps calling methods sans permission.

However, all else being equal, you should set your `targetSdkVersion` to at least 23 and opt into the runtime permission system.

What Happens if the User Clears My App's Data?

If the user clears your app's data through the Settings app, the runtime permissions are cleared as well. Behavior at this point will be as if your app had been just installed — `checkSelfPermission()` will return `PERMISSION_DENIED`, and you will need to request the permissions.

How Can I Automate Permission Grants?

While the runtime permission system provides a reasonable user-facing UI, having to deal with that UI constantly as a developer can be a significant pain. For testing and debugging purposes, there are some command-line options for granting and revoking permissions that you can use.

Should I Be Using PermissionChecker?

`checkSelfPermission()` on `ContextCompat` always returns `PERMISSION_GRANTED` if either:

- Your app has a `targetSdkVersion` below 23, or
- Your app is running on a device older than Android 6.0

`PERMISSION_DENIED` will be returned only if you have opted into the new runtime permission system (`targetSdkVersion` of 23 or higher), you are running on Android 6.0 or higher, and the user either never granted the permission or revoked it through the Settings app.

The key is that even if you are running on Android 6.0, with an older `targetSdkVersion` (so all permissions are requested at install time and are granted to you automatically), `checkSelfPermission()` still returns `PERMISSION_GRANTED` even if the user revoked the permission in Settings.

The Android Support libraries — specifically `support-v4` — added a `PermissionChecker` class with a `checkPermission()` static method. If you are running on Android 6.0+ with an older `targetSdkVersion`, `checkPermission()` will return `PERMISSION_DENIED_APP_OP` if the user revoked the permission in Settings.

Hence, `PermissionChecker` is useful in cases where you have a really large code base, and you want to try to better handle cases where users revoke permissions, but you are not in position to do a complete implementation of the runtime permissions

system. However, it is merely a stopgap — your long-term plan should be to raise your `targetSdkVersion` to 23 or higher and implement the runtime permissions properly.

A Simple Runtime Permission Abstraction

Occasionally, our need for runtime permissions is fairly straightforward: we need them to do anything meaningful in the app, and so we need to request them up front and exit the app if the user declines to grant one or more of them. Some of the samples in this book fit this model, in part because many of the samples in this book are fairly small apps.

Some of those apps will use a variation of an `AbstractPermissionActivity`, to hide all the runtime permission work, allowing the sample's "real" activity to focus on demonstrating the portion of the Android SDK that the sample is tied to.

One such `AbstractPermissionActivity` can be found in the `Files/FilesEditor` sample project. Later in the book, we will look at this sample to see how to do file I/O on Android. Here, though, let's take a look at `AbstractPermissionActivity`.

Examining the Protocol

The idea is that `AbstractPermissionActivity` will handle the runtime permissions, in its `onCreate()` implementation. Subclasses will need to implement three methods to make this work:

- `getDesiredPermissions()`, which returns the names of the permissions that the app wants
- `onReady()`, which will be called once permission is granted by the user, and serves as an `onCreate()` substitute for the subclass
- `onPermissionDenied()`, which will be called if the user declines granting the permission, so the subclass can do something (e.g., show a `Toast`, then `finish()` and go away)

Requesting the Permission

`onCreate()` will see if we have the desired permissions, and if not, it will call `requestPermissions()` to ask for those that we do not already hold:

```
@Override
protected void onCreate(Bundle savedInstanceState) {
  super.onCreate(savedInstanceState);

  this.state=savedInstanceState;

  if (state!=null) {
    isInPermission=state.getBoolean(STATE_IN_PERMISSION, false);
  }

  if (hasAllPermissions(getDesiredPermissions())) {
    onReady(state);
  }
  else if (!isInPermission) {
    isInPermission=true;

    ActivityCompat
      .requestPermissions(this,
        netPermissions(getDesiredPermissions()),
        REQUEST_PERMISSION);
  }
}
```

(from Files/FilesEditor/app/src/main/java/com/commonsware/android/fileseditor/AbstractPermissionActivity.java)

`hasAllPermissions()` iterates over the permission array from `getDesiredPermissions()` and returns `true` if we hold them all, `false` otherwise:

```
private boolean hasAllPermissions(String[] perms) {
  for (String perm : perms) {
    if (!hasPermission(perm)) {
      return(false);
    }
  }

  return(true);
}

protected boolean hasPermission(String perm) {
  return(ContextCompat.checkSelfPermission(this, perm)==
    PackageManager.PERMISSION_GRANTED);
}
```

(from Files/FilesEditor/app/src/main/java/com/commonsware/android/fileseditor/AbstractPermissionActivity.java)

If we hold all of the permissions, we go ahead and call `onReady()`, so the activity can start its real work. Otherwise, we call `requestPermissions()` on `ActivityCompat`,

using a `netPermissions()` method to identify those permissions that we do not already hold:

```
private String[] netPermissions(String[] wanted) {
  ArrayList<String> result=new ArrayList<String>();

  for (String perm : wanted) {
    if (!hasPermission(perm)) {
      result.add(perm);
    }
  }

  return(result.toArray(new String[result.size()]));
}
```

(from Files/FilesEditor/app/src/main/java/com/commonsware/android/fileseditor/AbstractPermissionActivity.java)

Handling the Result

In `onRequestPermissionResult()`, depending on whether we now hold all the desired permissions, we call `onReady()` or `onPermissionDenied()`:

```
@Override
public void onRequestPermissionsResult(int requestCode,
                                       String[] permissions,
                                       int[] grantResults) {
  isInPermission=false;

  if (requestCode==REQUEST_PERMISSION) {
    if (hasAllPermissions(getDesiredPermissions())) {
      onReady(state);
    }
    else {
      onPermissionDenied();
    }
  }
}
```

(from Files/FilesEditor/app/src/main/java/com/commonsware/android/fileseditor/AbstractPermissionActivity.java)

Dealing with (Configuration) Change

It is possible that the user will rotate the device or otherwise trigger a configuration change while our permission dialog is in the foreground. Since our activity is still

visible behind that dialog, we get destroyed and recreated... but we do not want to re-raise the permission dialog again.

That is why we have a `boolean`, named `isInPermission`, that tracks whether or not we are in the middle of requesting permissions. We hold onto that value in `onSaveInstanceState()`:

```
@Override
protected void onSaveInstanceState(Bundle outState) {
  super.onSaveInstanceState(outState);

  outState.putBoolean(STATE_IN_PERMISSION, isInPermission);
}
```

(from Files/FilesEditor/app/src/main/java/com/commonsware/android/fileseditor/AbstractPermissionActivity.java)

We restore it in `onCreate()`. If we do not hold all of the desired permissions, but `isInPermission` is `true`, we skip requesting the permissions, since we are in the middle of doing so already.

As noted earlier, later in the book, we will look at how a subclass of `AbstractPermissionActivity` works, and you will see `AbstractPermissionActivity` used in other sample apps as well.

Assets, Files, and Data Parsing

Android offers a few structured ways to store data, notably `SharedPreferences` and local SQLite databases. And, of course, you are welcome to store your data "in the cloud" by using an Internet-based service. We will get to all of those topics shortly.

Beyond that, though, Android allows you to work with plain old ordinary files, either ones baked into your app ("assets") or ones on so-called internal or external storage.

To make those files work — and to consume data off of the Internet — you will likely need to employ a parser. Android ships with several choices for XML and JSON parsing, in addition to third-party libraries you can attempt to use.

This chapter focuses on assets, files, and parsers.

Packaging Files with Your App

Let's suppose you have some static data you want to ship with the application, such as a list of words for a spell-checker. Somehow, you need to bundle that data with the application, in a way you can get at it from Java code later on, or possibly in a way you can pass to another component (e.g., `WebView` for bundled HTML files).

There are three main options here: raw resources, XML resources, and assets.

Raw Resources

One way to deploy a file like a spell-check catalog is to put the file in the `res/raw` directory, so it gets put in the Android application `.apk` file as part of the packaging process as a raw resource.

To access this file, you need to get yourself a `Resources` object. From an activity, that is as simple as calling `getResources()`. A `Resources` object offers `openRawResource()` to get an `InputStream` on the file you specify. Rather than a path, `openRawResource()` expects an integer identifier for the file as packaged. This works just like accessing widgets via `findViewById()` – if you put a file named `words.xml` in `res/raw`, the identifier is accessible in Java as `R.raw.words`.

Since you can only get an `InputStream`, you have no means of modifying this file. Hence, it is really only useful for static reference data. Moreover, since it is unchanging until the user installs an updated version of your application package, either the reference data has to be valid for the foreseeable future, or you will need to provide some means of updating the data. The simplest way to handle that is to use the reference data to bootstrap some other modifiable form of storage (e.g., a database), but this makes for two copies of the data in storage. An alternative is to keep the reference data as-is but keep modifications in a file or database, and merge them together when you need a complete picture of the information. For example, if your application ships a file of URLs, you could have a second file that tracks URLs added by the user or reference URLs that were deleted by the user.

XML Resources

If, however, your file is in an XML format, you are better served not putting it in `res/raw/`, but rather in `res/xml/`. This is a directory for XML resources – resources known to be in XML format, but without any assumptions about what that XML represents.

To access that XML, you once again get a `Resources` object by calling `getResources()` on your `Activity` or other `Context`. Then, call `getXml()` on the `Resources` object, supplying the ID value of your XML resource (e.g., `R.xml.words`). This will return an `XmlResourceParser`, which implements the `XmlPullParser` interface. We will discuss how to use this parser, and the performance advantage of using XML resources, later in this chapter.

As with raw resources, XML resources are read-only at runtime.

Assets

Your third option is to package the data in the form of an asset. You can create an `assets/` directory in your source set (e.g., `src/main/assets`), then place whatever files you want in there. Those are accessible at runtime by calling `getAssets()` on

your `Activity` or other `Context`, then calling `open()` with the path to the file (e.g., `assets/foo/index.html` would be retrieved via `open("foo/index.html")`). As with raw resources, this returns an `InputStream` on the file's contents. And, as with all types of resources, assets are read-only at runtime.

One benefit of using assets over raw resources is the `file:///android_asset/ Uri` prefix. You can use this to load an asset into a `WebView`. For example, for an asset located in `assets/foo/index.html` within your project, calling `loadUrl("file:///android_asset/foo/index.html")` will load that HTML into the `WebView`.

Note that assets are compressed when the APK is packaged. Unfortunately, on Android 1.x/2.x, this compression mechanism has a 1MB file size limit. If you wish to package an asset that is bigger than 1MB, you either need to give it a file extension that will not be compressed (e.g., `.mp3`) or actually store a ZIP file of the asset (to avoid the automatic compression) and decompress it yourself at runtime, using the standard `java.util.zip` classes. This restriction was lifted with Android 3.0, and so if your `minSdkVersion` is 11 or higher, this will not be an issue for you.

Files and Android

On the whole, Android just uses normal Java file I/O for local files. You will use the same `File` and `InputStream` and `OutputWriter` and other classes that you have used time and again in your prior Java development work.

What is distinctive in Android is *where* you read and write. Akin to writing a Java Web app, you do not have read and write access to arbitrary locations. Instead, there are only a handful of directories to which you have any access, particularly when running on production hardware.

Internal vs. External

Internal storage refers to your application's portion of the on-board, always-available flash storage.

External storage refers to storage space that can be mounted by the user as a drive in Windows (or, possibly with some difficulty, as a volume in macOS or Linux). Typically, this too is part of the on-board flash, though in a separate area than what is used for internal storage. Making things more complicated is that the *user* will tend to see this labeled as "Internal Storage" (e.g., in Settings); from the Android

SDK's standpoint, what the user thinks is "Internal Storage" is what the SDK calls external storage.

Standard vs. Cache

On both internal and external storage, you have the option of saving files as a cache, or on a more permanent basis. Files located in a cache directory may be deleted by the OS or third-party apps to free up storage space for the user. Files located outside of cache will remain unless manually deleted.

Yours vs. Somebody Else's

Internal storage is on a per-application basis. Files you write to in your own internal storage cannot be read or written to by other applications... normally. Users who "root" their phones can run apps with superuser privileges and be able to access your internal storage. Most users do not root their phones, and so only your app will be able to access your internal storage files.

Files on external storage, though, are visible to all applications and the user. Anyone can read anything stored there, and any application that requests to can write or delete anything it wants.

Working with Internal Storage

You have a few options for manipulating the contents of your app's portion of internal storage.

One possibility is to use `openFileInput()` and `openFileOutput()` on your `Activity` or other `Context` to get an `InputStream` and `OutputStream`, respectively. However, these methods do not accept file paths (e.g., `path/to/file.txt`), just simple filenames.

If you want to have a bit more flexibility, `getFilesDir()` and `getCacheDir()` return a `File` object pointing to the roots of your files and cache locations on internal storage, respectively. Given the `File`, you can create files and subdirectories as you see fit.

To see how this works, take a peek at the `Files/FilesEditor` sample project.

This application implements a tabbed editor, using a `ViewPager` and a third-party tab library. Each tab is an `EditorFragment`, implementing a large `EditText` widget, akin to what we saw as examples back in the chapter on `ViewPager`.

However, those `ViewPager` samples had no persistence. Whatever you typed stayed in the fragments but was lost when the process was terminated. `FileEditor` instead will save what you enter into files, one file per tab.

The layout for the activity is reminiscent of the `ViewPager` samples, except that we are using an `io.karim.MaterialTabs` widget for the tabs, instead of something like a `PagerTabStrip`:

```
<?xml version="1.0" encoding="utf-8"?>
<LinearLayout xmlns:android="http://schemas.android.com/apk/res/android"
              xmlns:app="http://schemas.android.com/apk/res-auto"
              android:layout_width="match_parent"
              android:layout_height="match_parent"
              android:orientation="vertical">

  <io.karim.MaterialTabs
    android:id="@+id/tabs"
    android:layout_width="match_parent"
    android:layout_height="48dp"
    app:mtIndicatorColor="@color/accent"
    app:mtSameWeightTabs="true"/>

  <android.support.v4.view.ViewPager
    android:id="@+id/pager"
    android:layout_width="match_parent"
    android:layout_height="match_parent">
  </android.support.v4.view.ViewPager>
</LinearLayout>
```

(from Files/FilesEditor/app/src/main/res/layout/main.xml)

That library, `io.karim:materialtabs`, is one of our dependencies, along with the `support-v13` library for `ViewPager` itself:

```
apply plugin: 'com.android.application'

dependencies {
    implementation 'io.karim:materialtabs:2.0.2'
    implementation 'com.android.support:support-v13:25.1.0'
}

android {
```

```
  compileSdkVersion 25
  buildToolsVersion '26.0.2'

  defaultConfig {
      minSdkVersion 15
      targetSdkVersion 25
  }
}
```

(from Files/FilesEditor/app/build.gradle)

Other than some slight tweaks for using a `MaterialTabs` for the tabs, the `MainActivity` is not significantly different than the original `ViewPager` examples. It loads up the layout and populates the `ViewPager` and tabs:

```
  @Override
  protected void onReady(Bundle savedInstanceState) {
    setContentView(R.layout.main);

    ViewPager pager=(ViewPager)findViewById(R.id.pager);

    pager.setAdapter(new SampleAdapter(this, getFragmentManager()));

    MaterialTabs tabs=(MaterialTabs)findViewById(R.id.tabs);
    tabs.setViewPager(pager);
  }
```

(from Files/FilesEditor/app/src/main/java/com/commonsware/android/fileseditor/MainActivity.java)

Where things start to depart more significantly from the original samples comes in `SampleAdapter`. Rather than 10 pages, we limit the number of tabs to 2 or 3 in `getCount()`. Whether we support 2 or 3 pages depends on what version of Android we are running on — we will explore this issue more later in this chapter.

Rather than delegate the page titles to the `EditorFragment`, `getPageTitle()` looks up a string resource value from an array, based on the position, and uses that for the title. And `getItem()`... becomes more complicated:

```
package com.commonsware.android.fileseditor;

import android.app.Fragment;
import android.app.FragmentManager;
import android.content.Context;
import android.os.Build;
import android.os.Environment;
import android.support.v13.app.FragmentPagerAdapter;
import java.io.File;
```

```
public class SampleAdapter extends FragmentPagerAdapter {
  private static final int[] TITLES={R.string.internal,
      R.string.external, R.string.pub};
  private static final int TAB_INTERNAL=0;
  private static final int TAB_EXTERNAL=1;
  private static final String FILENAME="test.txt";
  private final Context ctxt;

  public SampleAdapter(Context ctxt, FragmentManager mgr) {
    super(mgr);

    this.ctxt=ctxt;
  }

  @Override
  public int getCount() {
    return(3);
  }

  @Override
  public Fragment getItem(int position) {
    File fileToEdit;

    switch(position) {
      case TAB_INTERNAL:
        fileToEdit=new File(ctxt.getFilesDir(), FILENAME);
        break;

      case TAB_EXTERNAL:
        fileToEdit=new File(ctxt.getExternalFilesDir(null), FILENAME);
        break;

      default:
        fileToEdit=
            new File(Environment.
                  getExternalStoragePublicDirectory(Environment.DIRECTORY_DOCUMENTS),
                FILENAME);
        break;
    }

    return(EditorFragment.newInstance(fileToEdit));
  }

  @Override
  public String getPageTitle(int position) {
    return(ctxt.getString(TITLES[position]));
  }
}
```

(from Files/FilesEditor/app/src/main/java/com/commonsware/android/fileseditor/SampleAdapter.java)

Based on the supplied `position`, we create a `File` object representing where the data resides for our `EditorFragment`. Right now, let's focus on the `TAB_INTERNAL` case, where we use `getFilesDir()` to create a `File` object pointing to a `test.txt` file on our internal storage.

The `newInstance()` factory method on `EditorFragment` now takes the `File` object as input, instead of the `position`. A `File` is `Serializable`, and so we can put a `File` into the arguments `Bundle`:

```
static EditorFragment newInstance(File fileToEdit) {
  EditorFragment frag=new EditorFragment();
  Bundle args=new Bundle();

  args.putSerializable(KEY_FILE, fileToEdit);
  frag.setArguments(args);

  return(frag);
}
```

(from Files/FilesEditor/app/src/main/java/com/commonsware/android/fileseditor/EditorFragment.java)

In `onCreateView()` of `EditorFragment`, we inflate a layout that contains our large `EditText` widget and retrieve that `EditText` widget:

```
@Override
public View onCreateView(LayoutInflater inflater,
                         ViewGroup container,
                         Bundle savedInstanceState) {
  View result=inflater.inflate(R.layout.editor, container, false);

  editor=(EditText)result.findViewById(R.id.editor);

  return(result);
}
```

(from Files/FilesEditor/app/src/main/java/com/commonsware/android/fileseditor/EditorFragment.java)

In addition to an `editor` field for our `EditText`, `EditorFragment` has two other fields. One is a `LoadTextTask`, an `AsyncTask` subclass that we will use to load text from our file into our `EditText`. The other is `loaded`, a simple `boolean` to see if we have loaded our text yet:

```
private EditText editor;
private LoadTextTask loadTask=null;
private boolean loaded=false;
```

(from Files/FilesEditor/app/src/main/java/com/commonsware/android/fileseditor/EditorFragment.java)

In `onViewCreated()`, if we have not yet loaded the text, we kick off a `LoadTextTask` to do just that, passing in the `File` that we put into the arguments `Bundle`:

```
@Override
public void onViewCreated(View view, Bundle savedInstanceState) {
  super.onViewCreated(view, savedInstanceState);

  if (!loaded) {
    loadTask=new LoadTextTask();
    loadTask.executeOnExecutor(AsyncTask.THREAD_POOL_EXECUTOR,
        (File)getArguments().getSerializable(KEY_FILE));
  }
}
```

(from Files/FilesEditor/app/src/main/java/com/commonsware/android/fileseditor/EditorFragment.java)

`LoadTextTask`, in `doInBackground()`, goes through a typical Java file I/O read-all-the-lines process to read in a text file, if it exists. The resulting string is poured into the `EditText`. In `onPostExecute()`, it updates the `EditText` with the read-in text, plus clears the `loadTask` field and sets `loaded` to `true`:

```
private class LoadTextTask extends AsyncTask<File, Void, String> {
  @Override
  protected String doInBackground(File... files) {
    String result=null;

    if (files[0].exists()) {
      BufferedReader br;

      try {
        br=new BufferedReader(new FileReader(files[0]));

        try {
          StringBuilder sb=new StringBuilder();
          String line=br.readLine();

          while (line!=null) {
            sb.append(line);
            sb.append("\n");
            line=br.readLine();
          }

          result=sb.toString();
        }
        finally {
          br.close();
        }
      }
      catch (IOException e) {
        Log.e(getClass().getSimpleName(), "Exception reading file", e);
```

```
      }
    }

    return(result);
  }

  @Override
  protected void onPostExecute(String s) {
    editor.setText(s);
    loadTask=null;
    loaded=true;
  }
}
```

(from Files/FilesEditor/app/src/main/java/com/commonsware/android/fileseditor/EditorFragment.java)

However, since we are using an `AsyncTask`, we should retain this fragment:

```
@Override
public void onCreate(Bundle savedInstanceState) {
  super.onCreate(savedInstanceState);

  setRetainInstance(true);
}
```

(from Files/FilesEditor/app/src/main/java/com/commonsware/android/fileseditor/EditorFragment.java)

...and in `onDestroy()`, we should `cancel()` this task if it is still running, as we no longer need the results:

```
@Override
public void onDestroy() {
  if (loadTask!=null) {
    loadTask.cancel(false);
  }

  super.onDestroy();
}
```

(from Files/FilesEditor/app/src/main/java/com/commonsware/android/fileseditor/EditorFragment.java)

Rather than have some dedicated "save" action bar item or similar UI element, we can just arrange to save the data when our fragment gets paused. This is a typical approach in Android apps, as users do not necessarily get an opportunity to click some "save" UI element, if they get interrupted by a phone call or something. So, in `onPause()`, we kick off a `SaveThread` to write our `EditText` contents to the same `File`, once again pulled from the arguments `Bundle`:

```
@Override
public void onPause() {
  if (loaded) {
    new SaveThread(editor.getText().toString(),
        (File)getArguments().getSerializable(KEY_FILE)).start();
  }

  super.onPause();
}
```

(from Files/FilesEditor/app/src/main/java/com/commonsware/android/fileseditor/EditorFragment.java)

However, note that we do not fork the `SaveThread` if `loaded` is still `false`. In that case, we know that we are still loading in the text, which means the text cannot possibly have been modified by the user, so there is nothing to save.

`SaveThread` ensures that the directory we want to write to exists (as it may or may not exist, particularly on emulators), then uses Java `Writer` objects to write out our text. Since there is nothing that we want to do with the UI here, a plain `Thread`, rather than an `AsyncTask`, is a better solution:

```
private static class SaveThread extends Thread {
  private final String text;
  private final File fileToEdit;

  SaveThread(String text, File fileToEdit) {
    this.text=text;
    this.fileToEdit=fileToEdit;
  }

  @Override
  public void run() {
    try {
      fileToEdit.getParentFile().mkdirs();

      FileOutputStream fos=new FileOutputStream(fileToEdit);

      Writer w=new BufferedWriter(new OutputStreamWriter(fos));

      try {
        w.write(text);
        w.flush();
        fos.getFD().sync();
      }
      finally {
        w.close();
      }
```

```
    }
    catch (IOException e) {
      Log.e(getClass().getSimpleName(), "Exception writing file", e);
    }
  }
}
```

(from Files/FilesEditor/app/src/main/java/com/commonsware/android/fileseditor/EditorFragment.java)

The reason for using a `FileOutputStream`, and that mysterious `getFD().sync()` part, will be covered later in this chapter.

The result is a set of tabbed editors, where the first one is our one for internal storage:

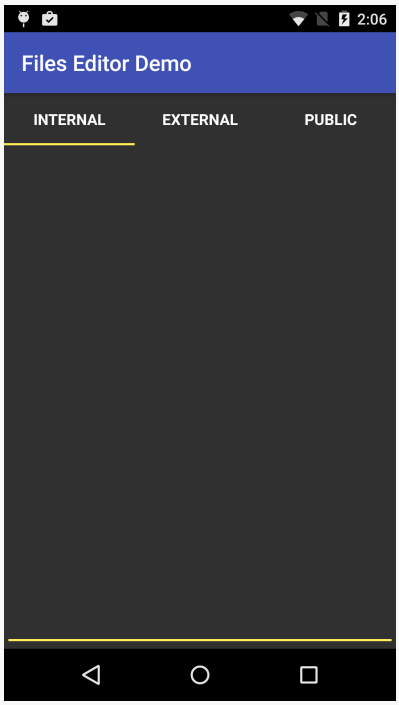

Figure 268: FilesEditor Sample, As Initially Launched

If you type something into the "Internal" tab, press BACK to exit the activity, and go back into the app again, whatever you typed in will be re-loaded from disk and will show up in the editor.

The files stored in internal storage are accessible only to your application, by default. Other applications on the device have no rights to read, let alone write, to this space.

However, bear in mind that some users "root" their Android phones, gaining superuser access. These users will be able to read and write whatever files they wish. As a result, please consider application-local files to be secure against malware but not necessarily secure against interested users.

Working with External Storage

Like internal storage, external storage can be used with ordinary Java file I/O (e.g., the `File` class). What differs is where you can read or write. And, compared to internal storage, what differs is whether you are *allowed* to read or write.

Where to Write

If you have files that are tied to your application that are simply too big to risk putting in internal storage, or if the user should be able to download the files off their device at will, you can use `getExternalFilesDir()`, available on any activity or other `Context`. This will give you a `File` object pointing to an automatically-created directory on external storage, unique for your application. While not secure against other applications, it does have one big advantage: when your application is uninstalled, these files are automatically deleted, just like the ones in the application-local file area. This method was added in API Level 8. This method takes one parameter — typically `null` — that indicates a particular type of file you are trying to save (or, later, load).

In `SampleAdapter` of the sample app, if the user chooses the "External" tab, we use `getExternalFilesDir()` to create the `File` to be used by the `EditorFragment`:

```
      case TAB_EXTERNAL:
        fileToEdit=new File(ctxt.getExternalFilesDir(null), FILENAME);
        break;
```

(from Files/FilesEditor/app/src/main/java/com/commonsware/android/fileseditor/SampleAdapter.java)

There is also `getExternalCacheDir()`, which returns a `File` pointing at a directory that contains files that you would like to have, but if Android or a third-party app clears the cache, your app will continue to function normally.

If you have files that belong more to the user than to your app — pictures taken by the camera, downloaded MP3 files, etc. — a better solution is to use `getExternalStoragePublicDirectory()`, available on the `Environment` class. This will give you a `File` object pointing to a directory set aside for a certain type of file,

based on the type you pass into `getExternalStoragePublicDirectory()`. For example, you can ask for `DIRECTORY_MOVIES`, `DIRECTORY_MUSIC`, or `DIRECTORY_PICTURES` for storing MP4, MP3, or JPEG files, respectively. These files will be left behind when your application is uninstalled. This method was also added in API Level 8.

In `SampleAdapter` of the sample app, if the user chooses the "Public" tab, we use `getExternalStoragePublicDirectory()` to create the `File` to be used by the `EditorFragment`, putting our file in the `DIRECTORY_DOCUMENTS` location:

```
    default:
      fileToEdit=
          new File(Environment.
                getExternalStoragePublicDirectory(Environment.DIRECTORY_DOCUMENTS),
              FILENAME);
      break;
```

(from Files/FilesEditor/app/src/main/java/com/commonsware/android/fileseditor/SampleAdapter.java)

You will also find a `getExternalStorageDirectory()` method on `Environment`, pointing to the root of the external storage. This is no longer the preferred approach — the methods described above help keep the user's files better organized. However, if you are supporting older Android devices, you may need to use `getExternalStorageDirectory()`, simply because the newer options may not be available to you.

Relevant Permissions

On all relevant Android versions prior to Android 4.4 (API Level 19), if you want to write to external storage, you need to hold the `WRITE_EXTERNAL_STORAGE` permission. And, on those versions, you do not need a permission to read from external storage.

On Android 4.4 and up, the rules are a bit different:

- To read or write in the directory trees rooted at `getExternalFilesDir()` and `getExternalCacheDir()`, you do not need a permission
- To write to anywhere else on external storage, you need `WRITE_EXTERNAL_STORAGE`
- To read from anywhere else on external storage, you need either `WRITE_EXTERNAL_STORAGE` (if you already have that) or `READ_EXTERNAL_STORAGE` (if not)

Hence, so long as your `android:minSdkVersion` is less than 19, you need to take the most conservative approach:

- If you are writing *anywhere* on external storage, request the `WRITE_EXTERNAL_STORAGE` permission
- If you are only reading, but from *anywhere* on external storage, request the `READ_EXTERNAL_STORAGE` permission

Note that you might get paths to external storage locations from third-party apps, typically in the form of a `Uri`. If you are handling `Uri` values from third-party apps, you should request `READ_EXTERNAL_STORAGE` or `WRITE_EXTERNAL_STORAGE`, in case the third-party app hands you a `Uri` pointing to external storage.

For example, here is the sample app's manifest, complete with the `<uses-permission>` element for `WRITE_EXTERNAL_STORAGE`:

```
<?xml version="1.0"?>
<manifest package="com.commonsware.android.fileseditor"
  xmlns:android="http://schemas.android.com/apk/res/android"
  android:versionCode="1"
  android:versionName="1.0">

  <uses-permission android:name="android.permission.WRITE_EXTERNAL_STORAGE" />

  <supports-screens
    android:anyDensity="true"
    android:largeScreens="true"
    android:normalScreens="true"
    android:smallScreens="true" />

  <application
    android:icon="@drawable/ic_launcher"
    android:label="@string/app_name"
    android:theme="@style/Theme.Apptheme">
    <activity
      android:name=".MainActivity"
      android:label="@string/app_name">
      <intent-filter>
        <action android:name="android.intent.action.MAIN" />

        <category android:name="android.intent.category.LAUNCHER" />
      </intent-filter>
    </activity>
  </application>
```

```
</manifest>
```

(from Files/FilesEditor/app/src/main/AndroidManifest.xml)

However, on Android 6.0+, `WRITE_EXTERNAL_STORAGE` is one of those `dangerous` permissions that we have to request at runtime. That is why this sample app uses the `AbstractPermissionActivity` profiled in the material on runtime permissions. Overall, our `MainActivity` looks like this:

```
package com.commonsware.android.fileseditor;

import android.os.Bundle;
import android.support.v4.view.ViewPager;
import android.widget.Toast;
import io.karim.MaterialTabs;
import static android.Manifest.permission.WRITE_EXTERNAL_STORAGE;

public class MainActivity extends AbstractPermissionActivity  {
  @Override
  protected String[] getDesiredPermissions() {
    return(new String[]{WRITE_EXTERNAL_STORAGE});
  }

  @Override
  protected void onPermissionDenied() {
    Toast
      .makeText(this, R.string.msg_sorry, Toast.LENGTH_LONG)
      .show();
    finish();
  }

  @Override
  protected void onReady(Bundle savedInstanceState) {
    setContentView(R.layout.main);

    ViewPager pager=(ViewPager)findViewById(R.id.pager);

    pager.setAdapter(new SampleAdapter(this, getFragmentManager()));

    MaterialTabs tabs=(MaterialTabs)findViewById(R.id.tabs);
    tabs.setViewPager(pager);
  }
}
```

(from Files/FilesEditor/app/src/main/java/com/commonsware/android/fileseditor/MainActivity.java)

`getDesiredPermissions()` indicates that we want `WRITE_EXTERNAL_STORAGE`, and `onPermissionDenied()` exits the app after showing a `Toast`. `onReady()` is where we set up the tabs, as we now have all the permissions that we need to be able to work with external storage.

Note that we do *not* need `WRITE_EXTERNAL_STORAGE` for `getExternalFilesDir()` on API Level 19+ devices. This leads to another possible permission strategy for this app:

- We could add `android:maxSdkVersion="18"` to the `<uses-permission>` element for `WRITE_EXTERNAL_STORAGE`. This would indicate that we only want this permission on devices that are running API Level 18 or lower.
- We could then have `SampleAdapter` see what version of Android we are running on. If we are running on API Level 19 or higher, we know that we did not request `WRITE_EXTERNAL_STORAGE`, but that we do not need that permission for `getExternalFilesDir()`. In that case, we could suppress the "Public" tab (since we do not have permission to write there) and only show two tabs. But, on older devices where we *did* ask for that permission, we could show all three tabs (since we have rights for all of external storage).

When to Write

Also, external storage may be tied up by the user having mounted it as a USB storage device. You can use `getExternalStorageState()` (a static method on `Environment`) to determine if external storage is presently available or not. On Android 3.0 and higher, this should be much less of an issue, as they changed how the external storage is used by the host PC — originally, this used USB Mass Storage Mode (think thumb drives) and now uses the USB Media Transfer Protocol (think MP3 players). With MTP, both the Android device and the PC it is connected to can have access to the files simultaneously; Mass Storage Mode would only allow the host PC to have access to the files if external storage is mounted.

Nowadays, you can use `getStorageState()` on the `EnvironmentCompat` class from the `support-v4` library to find out the state of external storage, for the particular `File` passed as a parameter.

Letting the User See Your Files

The switch to MTP has one side-effect for Android developers: files you write to external storage may not be automatically visible to the user. At the time of this

writing, the only files that will show up on the user's PC will be ones that have been indexed by the `MediaStore`. While the `MediaStore` is typically thought of as only indexing "media" (images, audio files, video files, etc.), it was given the added role in Android 3.0 of maintaining an index of *all* files for the purposes of MTP.

Your file that you place on external storage will not be indexed automatically simply by creating it and writing to it. Eventually, it will be indexed, though it may be quite some time for an automatic indexing pass to take place.

To force Android to index your file, you can use `scanFile()` on `MediaScannerConnection`:

```
String[] paths={pathToYourNewFileOnExternalStorage};
MediaScannerConnection.scanFile(this, paths, null, null);
```

The third parameter to `scanFile()` is an array of MIME types, to line up with the array of paths in the second parameter. If your file is some form of media, and you know the MIME type, supplying that will ensure that your media will be visible as appropriate to the right apps (e.g., images in the Gallery app). Otherwise, Android will try to infer a MIME type from the file extension.

In the sample app, since the `EditorFragment` does not know whether the file is on external storage and therefore is reachable, it does not know whether or not this sort of indexing is appropriate. In a more conventional scenario, where the `EditorFragment` would consistently be writing to external storage, `SaveThread` could arrange to invoke `MediaScannerConnection` as part of its work. However, `scanFile()` needs a `Context`, and so the `SaveThread` would need one of those. You would wind up with something a bit like:

```
  private static class SaveThread extends Thread {
    private final String text;
    private final File fileToEdit;
    private final Context ctxt;

    SaveThread(Context ctxt, String text, File fileToEdit) {
      this.ctxt=ctxt.getApplicationContext();
      this.text=text;
      this.fileToEdit=fileToEdit;
    }

    @Override
    public void run() {
      try {
```

```
      fileToEdit.getParentFile().mkdirs();

      FileOutputStream fos=new FileOutputStream(fileToEdit);

      Writer w=new BufferedWriter(new OutputStreamWriter(fos));

      try {
        w.write(text);
        w.flush();
        fos.getFD().sync();
      }
      finally {
        w.close();
        String[] paths={fileToEdit.getAbsolutePath()};
        MediaScannerConnection.scanFile(ctxt, paths, null, null);
      }
    }
    catch (IOException e) {
      Log.e(getClass().getSimpleName(), "Exception writing file", e);
    }
  }
}
```

Here, we use `getApplicationContext()`, which returns to us a `Context` that is a process-wide singleton. That way, if our activity is destroyed while the thread is still running, we still have a valid `Context` to use.

Limits on External Storage Open Files

Many Android devices will have a per-process limit of 1024 open files, on any sort of storage. This is usually not a problem for developers.

On some devices — including probably all that are running Android 4.2 and higher — there is a *global* limit of 1024 open files on external storage. In other words, all running apps combined can only open 1024 files simultaneously on external storage.

This means that it is important for you to minimize how many open files on external storage you have at a time. Having a few open files is perfectly reasonable; having a few hundred open files is not.

Removable Storage

Some Android devices support micro SD card slots, where cards inserted in there are not part of internal or external storage. Some Android devices support USB On-The-Go (OTG) drives. Some Android devices support other forms of removable storage, such as full-size SD cards, full-size USB thumb drives, etc.

And, until Android 4.4, none of that was officially available to you as a developer.

What You Can Do

Android 4.4 (API Level 19) added two new methods, `getExternalCacheDirs()` and `getExternalFilesDirs()`, the plural versions of the classic methods. These return an array of `File` objects, representing one *or more* places where your app can work with external storage. The first element in the array will be the same `File` object returned by the singular versions of the methods (e.g., `getExternalFilesDir()`). The other elements in the array, if any, will represent app-specific directories on removable storage location. The Android Support package has a `ContextCompat` class containing static versions of `getExternalCacheDirs()` and `getExternalFilesDirs()`, so you can use the same code on API Level 4 and above, though the backport will only ever return one directory in the array.

What You Can't Do

You cannot access arbitrary files on removable storage. You have full read/write access to the specific locations referred to by the aforementioned methods, but that is all that you are guaranteed access to. So, you cannot write code that iterates over all the files on removable storage, for example.

The Workarounds

The Storage Access Framework allows you to work with content on removable storage, and in cloud storage providers, though not using `File`.

The `MediaStore` contains an index of all files on external storage and removable storage. You can query for content from certain MIME types (e.g., all videos) and be able to read in that content. However, once again, you are not using `File`.

Multiple User Accounts

On Android 4.1 and earlier, each Android device was assumed to be used by just one person.

On Android 4.2+ tablets — and Android 5.0+ phones — it is possible for a device's owner to set up multiple user accounts. Each user gets their own section of internal and external storage for files, databases, `SharedPreferences`, and so forth. From your standpoint, it is as if the users are really on different devices, even though in reality it is all the same hardware.

However, this means that paths to internal and external storage now may vary by user. Hence, it is *very important* for you to use the appropriate methods, outlined in this chapter, for finding locations on internal storage (e.g., `getFilesDir()`) and external storage (e.g., `getExternalFilesDir()`).

Some blog posts, Stack Overflow answers, and the like will show the use of hard-coded paths for these locations (e.g., `/sdcard` or `/mnt/sdcard` for the root of external storage). Hard-coding such paths was never a good idea. And, as of Android 4.2, those paths are simply wrong and will not work.

On Android 4.2+, for the original user of the device, internal storage will wind up in the same location as before, but external storage will use a different path. For the second and subsequent users defined on the device, both internal and external storage will reside in different paths. The various methods, like `getFilesDir()`, will handle this transparently for you.

Note that, at the time of this writing, multiple accounts are not available on the emulators, only on actual tablets. Phones usually will not have multiple-account support, under the premise that tablets are more likely to be shared than are phones.

Linux Filesystems: You Sync, You Win

Android is built atop a Linux kernel and uses Linux filesystems for holding its files. Classically, Android used YAFFS (Yet Another Flash File System), optimized for use on low-power devices for storing data to flash memory.

YAFFS has one big problem: only one process can write to the filesystem at a time. For those of you into filesystems, rather than offering file-level locking, YAFFS has

partition-level locking. This can become a bit of a bottleneck, particularly as Android devices grow in power and start wanting to do more things at the same time like their desktop and notebook brethren.

Android 3.0 switched to ext4, another Linux filesystem aimed more at desktops/notebooks. Your applications will not directly perceive the difference. However, ext4 does a fair bit of buffering, and it can cause problems for applications that do not take this buffering into account. Linux application developers ran headlong into this in 2008-2009, when ext4 started to become popular. Android developers will need to think about it now... for your own file storage.

If you are using SQLite or `SharedPreferences`, you do not need to worry about this problem. Android (and SQLite, in the case of SQLite) handle all the buffering issues for you. If, however, you write your own files, you may wish to contemplate an extra step as you flush your data to disk. Specifically, you need to trigger a Linux system call known as `fsync()`, which tells the filesystem to ensure all buffers are written to disk.

If you are using `java.io.RandomAccessFile` in a synchronous mode, this step is handled for you as well, so you will not need to worry about it. However, Java developers tend to use `FileOutputStream`, which does not trigger an `fsync()`, even when you call `close()` on the stream. Instead, you call `getFD().sync()` on the `FileOutputStream` to trigger the `fsync()`. Note that this may be time-consuming, and so disk writes should be done off the main application thread wherever practical, such as via an `AsyncTask`.

This is why, in `EditorFragment`, our `SaveThread` implementation looks like this:

```
private static class SaveThread extends Thread {
  private final String text;
  private final File fileToEdit;

  SaveThread(String text, File fileToEdit) {
    this.text=text;
    this.fileToEdit=fileToEdit;
  }

  @Override
  public void run() {
    try {
      fileToEdit.getParentFile().mkdirs();

      FileOutputStream fos=new FileOutputStream(fileToEdit);
```

```
      Writer w=new BufferedWriter(new OutputStreamWriter(fos));

      try {
        w.write(text);
        w.flush();
        fos.getFD().sync();
      }
      finally {
        w.close();
      }
    }
    catch (IOException e) {
      Log.e(getClass().getSimpleName(), "Exception writing file", e);
    }
  }
}
```

(from Files/FilesEditor/app/src/main/java/com/commonsware/android/fileseditor/EditorFragment.java)

While we use a `Writer` to do the writing, it is wrapped around a `FileOutputStream`, so we can get access to the `FileDescriptor` (via `getFD()`) and call `sync()` on it.

StrictMode: Avoiding Janky Code

Users are more likely to like your application if, to them, it feels responsive. Here, by "responsive", we mean that it reacts swiftly and accurately to user operations, like taps and swipes.

Conversely, users are less likely to be happy with you if they perceive that your UI is "janky" — sluggish to respond to their requests. For example, maybe your lists do not scroll as smoothly as they would like, or tapping a button does not yield the immediate results they seek.

While threads and `AsyncTask` and the like can help, it may not always be obvious where you should be applying them. A full-scale performance analysis, using Traceview or similar Android tools, is certainly possible. However, there are a few standard sorts of things that developers do, sometimes quite by accident, on the main application thread that will tend to cause sluggishness:

1. Flash I/O, both for internal and external storage
2. Network I/O

However, even here, it may not be obvious that you are performing these operations on the main application thread. This is particularly true when the operations are really being done by Android's code that you are simply calling.

That is where `StrictMode` comes in. Its mission is to help you determine when you are doing things on the main application thread that might cause a janky user experience.

`StrictMode` works on a set of policies. There are presently two categories of policies: VM policies and thread policies. The former represent bad coding practices that pertain to your entire application, notably leaking SQLite `Cursor` objects and kin. The latter represent things that are bad when performed on the main application thread, notably flash I/O and network I/O.

Each policy dictates what `StrictMode` should watch for (e.g., flash reads are OK but flash writes are not) and how `StrictMode` should react when you violate the rules, such as:

1. Log a message to Logcat
2. Display a dialog
3. Crash your application (seriously!)

The simplest thing to do is call the static `enableDefaults()` method on `StrictMode` from `onCreate()` of your first activity. This will set up normal operation, reporting all violations by simply logging to Logcat. However, you can set your own custom policies via `Builder` objects if you so choose.

However, do not use `StrictMode` in production code. It is designed for use when you are building, testing, and debugging your application. It is not designed to be used in the field.

So, for example, you might have something like this in your launcher activity:

```
StrictMode.ThreadPolicy.Builder b=new StrictMode.ThreadPolicy.Builder();

if (BuildConfig.DEBUG) {
  b.detectAll().penaltyDeath();
}
else {
  b.detectAll().penaltyLog();
}

StrictMode.setThreadPolicy(b.build());
```

`BuildConfig.DEBUG` will be `true` for debuggable builds, false otherwise. So, in the case of a debug build, we want to detect all mistakes and crash the app immediately when we encounter them, but in production, we want to just log information about the mistake to Logcat.

You will note that the sample app does not contain this code. That is because calling methods like `getFilesDir()` and `getExternalFilesDir()` really ought to be on background threads, as `StrictMode` will complain about them. Hence, this code would cause `SampleAdapter` to crash when it tries building the `File` object to use. This could be rectified by having `SampleAdapter` simply pass in a flag indicating the storage location and having `LoadThreadTask` and `SaveThread` deal with the `File` objects.

Note that `StrictMode` will also report leaked open files. For example, if you create a `FileOutputStream` on a `File` and fail to `close()` it later, when the `FileOutputStream` (and related objects) are garbage-collected, `StrictMode` will report to you the fact that you failed to close the stream. This is very useful to help you make sure that you are not leaking open files that may contribute to exhausting the 1,024 open file limit on external storage.

Files, and Your Development Machine

All this reading and writing of data is nice, but for debugging and diagnostic purposes, it is often useful for you to be able to look at the files, other than through your app.

This is somewhat challenging, due to the lack of tools and due to security restrictions in production devices (as compared to emulators).

That being said, the following sections will outline some options that you have to access your app's files independently of your app.

Mounting as a Drive

If you have an actual Android device, when you plug it in via a USB cable, usually you will get external storage available as a drive letter (Windows) or a mounted volume (macOS and Linux). Depending upon the device, manufacturer, and configuration, you might also have access to removable storage this way as well.

In these cases, you can use your development machine's OS to poke around these file locations and look at your files (or anyone else's).

However, there are some wrinkles:

- On Android 6.0+, by default, a USB connection is only used for charging. You need to slide open the notification tray and tap on the `Notification` for the USB connection, to toggle it to share files using MTP.
- Some versions of macOS and Linux will require you to install additional software to view files over MTP.
- If you see a volume name labeled "Internal Storage", that is really external storage, because confusing people is fun, apparently.
- You cannot get to what the Android SDK refers to as internal storage by this means.

Browsing Files Via Android Studio

Android Studio 3.0+ offers a Device File Explorer tool. As the name suggests, it allows you to explore the filesystems on an Android device (or emulator).

This tool is docked by default in the lower-right screen edge. When opened, it displays a fairly typical directory tree structure:

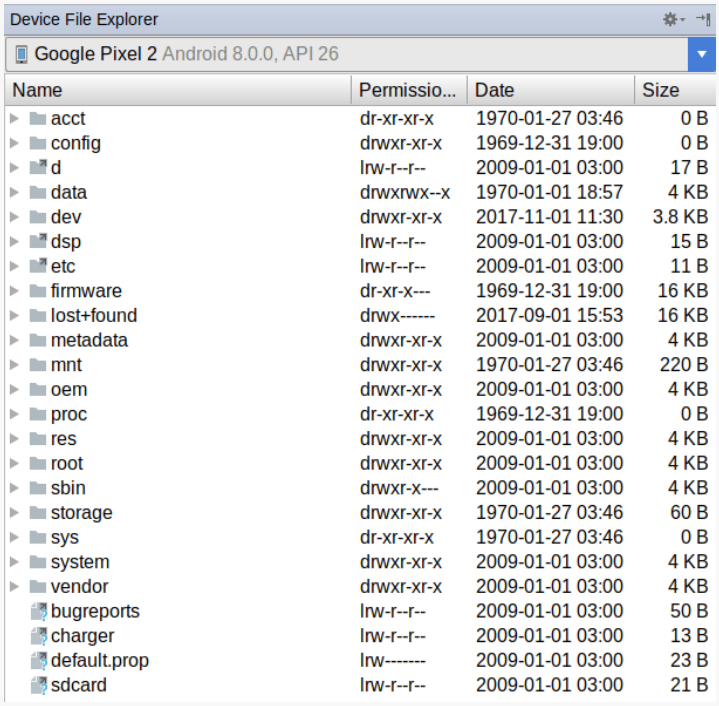

Figure 269: Device File Explorer, As Initially Opened

Key places to try browsing to are:

- `/data/data/.../`, where `...` is an application ID, to browse the internal storage for a particular app for the primary device user
- `/sdcard/` or `/mnt/sdcard/`, which will be typical (though not universal) ways of reaching external storage

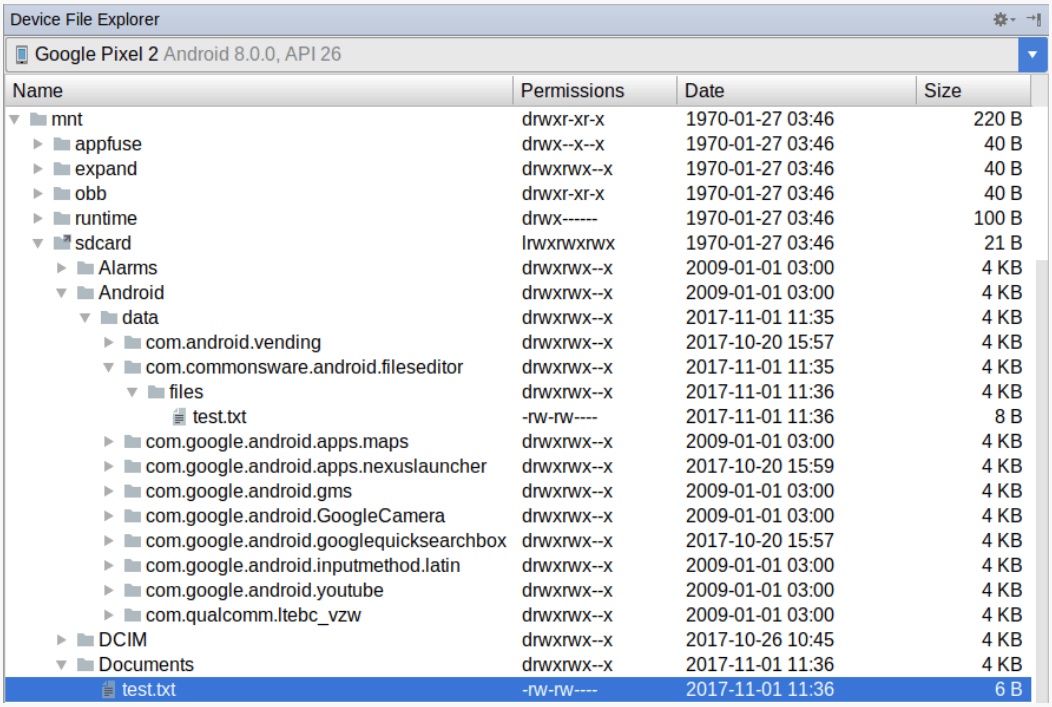

Figure 270: Device File Explorer, Showing External and Public FilesEditor Files

However, for hardware and emulators with the Google proprietary apps (e.g., Play Store), you will only be able to browse into internal storage of debuggable apps. The Explorer has no ability to browse into production apps in these environments:

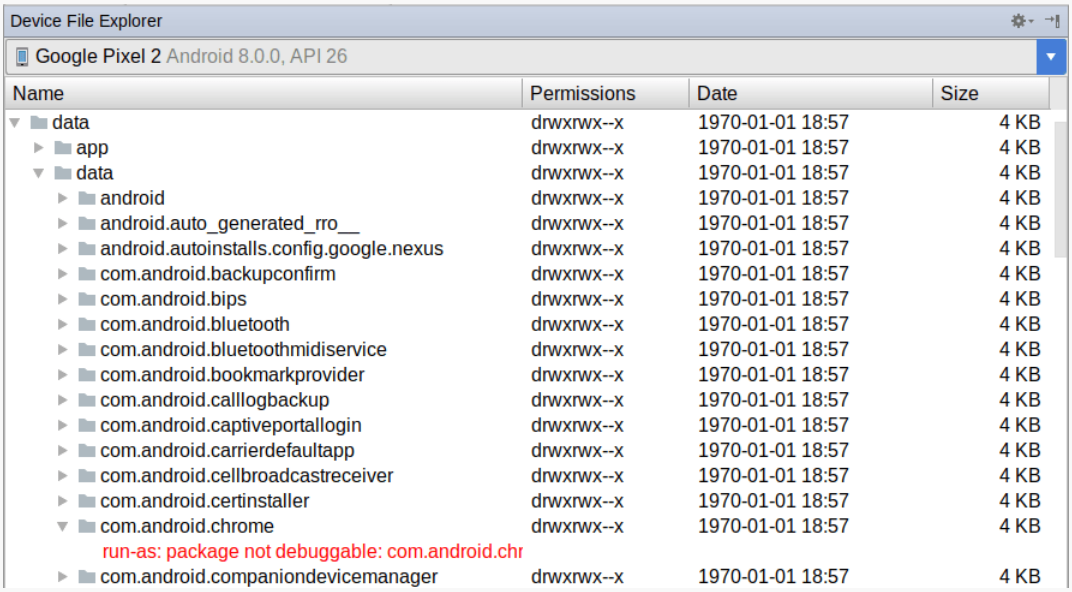

Figure 271: Device File Explorer, Showing Blocked Access to Chrome's Files

On an emulator that lacks the Google proprietary apps, though, you can browse much more of the filesystem, including the internal storage of production apps:

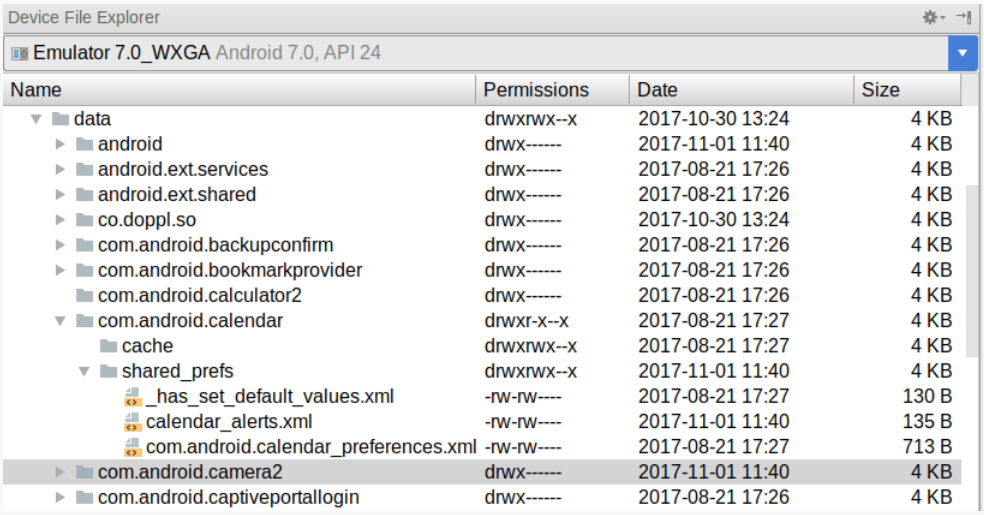

Figure 272: Device File Explorer, Showing Access to Calendar's Files on an Emulator

For any file that you can see, if it is of a recognized file type, double-clicking the file will open it up in Android Studio. That is because, at least on macOS and Linux, a virtual filesystem is added on your development machine that maps to the device or

emulator. You can find the location by looking at the "breadcrumbs" above the editor that show the segments of its local file path:

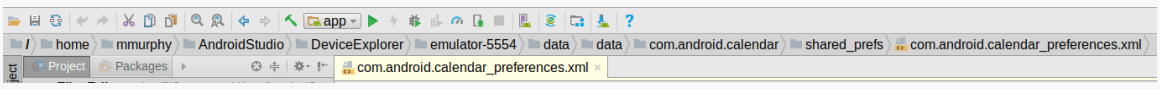

Figure 273: Breadcrumbs Showing Local Map to Emulator Filesystem

You can use that same path to work with the file using tools outside of Android Studio. However, changes that you make to the file through Android Studio will not be saved back to the device or emulator.

Right-clicking over a file will give you options to:

- Open it in Android Studio
- Save it to an arbitrary location on your development machine
- Delete it
- "Synchronize" it, which updates the UI from the filesystem
- Copy its on-device/on-emulator path to the clipboard, for pasting into Android app development books like this one:

```
/data/data/com.android.calendar/shared_prefs/com.android.calendar_preferences.xml
```

Right-clicking over a directory will give you options to:

- Create a new file or subdirectory in this directory
- Save the *contents* of this directory — though not the directory name itself — into a directory of your choice
- Upload a file or directory into this directory
- Delete the directory (recursively deleting all of its contents)
- "Synchronize" it, which updates the UI from the filesystem
- Copy its on-device/on-emulator path to the clipboard

Note that the Device File Explorer effectively shows a snapshot of what is on the device or emulator filesystem. It will only reflect changes if you use the Synchronize context menu option.

Push and Pull for External Storage

You can get at external storage of devices and emulators via the command-line `adb` tool. This program is in `platform-tools/` of your Android SDK installation, and it is

a good idea to add that directory to your operating system's PATH environment variable, so you can run adb from anywhere.

adb push and adb pull allow you to upload and download files, respectively. Both take the local path and the remote (device/emulator) path as command-line arguments, although in varying order:

- adb push localpath remotepath will upload the file represented by localpath to the location represented by remotepath
- adb pull remotepath localpath will download the file represented by remotepath to the location represented by localpath

For external storage, the root directory name varies by Android OS version:

- Android 1.x/2.x: use /sdcard/
- Android 4.x/5.x: use /mnt/shell/emulated/0/
- Android 6.0+: use /storage/emulated/0/.

So, for example, the following command would push an index.html file to the getExternalFilesDir() location for the primary device account, for an app whose application is your.package.name.here:

```
adb push index.html /storage/emulated/0/Android/data/your.package.name.here/files
```

If you try to push a local directory, or pull a remote directory, the contents of those directories will be uploaded and downloaded, respectively. However, the *directory* itself is not, which can cause some confusion.

Suppose we have a directory on our development PC named foo/. It contains four PNG files, named 1.png, 2.png, 3.png, and parallelism-is-boring.png. We then execute the following command on the command line:

```
adb push foo /storage/emulated/0/Android/data/your.package.name.here/files
```

You will wind up with:

- /storage/emulated/0/Android/data/your.package.name.here/files/1.png
- /storage/emulated/0/Android/data/your.package.name.here/files/2.png
- /storage/emulated/0/Android/data/your.package.name.here/files/3.png

- `/storage/emulated/0/Android/data/your.package.name.here/files/parallelism-is-boring.png`

Note, though, that the `foo` directory name is not included. In other words, the *contents* of `foo/` are transferred, but not `foo/` itself.

Run-As for Internal Storage

`adb push` and `adb pull` work directly for internal storage as well... on emulators.

On production hardware, though, you have some additional work to do. Specifically, you need to use external storage as an intermediary and use `adb run-as` to give yourself the temporary ability to work with internal storage.

For example, on an emulator, you could push `index.html` to the directory returned by `getFilesDir()`, for an app with an application ID of `your.package.name.here`, for the primary device account, via:

```
adb push index.html /data/data/your.package.name.here/files
```

If you try that on production hardware, it will fail. While the piece that `adb` communicates with on the emulator runs with superuser privileges, the equivalent piece on production hardware does not. The same security that prevents other apps from accessing your app's portion of internal storage prevents `adb` from doing so as well.

However, `adb` on production hardware *can* use the `run-as` command, to execute a Linux command as if it were being run by the Linux user associated with your app, the user that owns all your files and who has read/write access to those files.

So, the equivalent script to copy the file to internal storage on a production Android 4.x/5.x device would be:

```
adb push index.html /mnt/shell/emulated/0
adb shell run-as your.package.name.here cp /mnt/shell/emulated/0/index.html /data/
data/your.package.name.here/files
adb shell rm /mnt/shell/emulated/0/index.html
```

(note that the second command should appear all on one line, even though it may show up as word-wrapped here due to the length of the line and the available width of the book)

This will only work for debuggable apps, which is the normal state of apps that you run from your IDE. This script:

- Pushes the file to the root of external storage
- Uses `run-as` to run the Linux `cp` command to copy the file from external storage to the app's internal storage
- Runs the Linux `rm` command to remove the file that we placed on external storage

(if you are wondering why we do not use `mv` instead of `cp` and `rm`, `mv` generates errors related to attempting to change the ownership of the moved file)

XML Parsing Options

Android supports a fairly standard implementation of the Java DOM and SAX APIs. If you have existing experience with these, or if you have code that already leverages them, feel free to use them.

Android also bakes in the `XmlPullParser` from the xmlpull.org site. Like SAX, the `XmlPullParser` is an event-driven interface, compared to the DOM that builds up a complete data structure and hands you that result. Unlike SAX, which relies on a listener and callback methods, the `XmlPullParser` has you pull events off a queue, ignoring those you do not need and dispatching the rest as you see fit to the rest of your code.

The primary reason the `XmlPullParser` was put into Android was for XML-encoded resources. While you write plain-text XML during development, what is packaged in your APK file is a so-called "binary XML" format, where angle brackets and quotation marks and such are replaced by bitfields. This helps compression a bit, but mostly this conversion is done to speed up parsing. Android's XML resource parser can parse this "binary XML" approximately ten times faster than it can parse the equivalent plain-text XML. Hence, anything you put in an XML resource (`res/xml/`) will be parsed similarly quickly.

For plain-text XML content, the `XmlPullParser` is roughly equivalent, speed-wise, to SAX. All else being equal, lean towards SAX, simply because more developers will be familiar with it from classic Java development. However, if you really like the `XmlPullParser` interface, feel free to use it.

You are welcome to try a third-party XML parser JAR, but bear in mind that there may be issues when trying to get it working in Android.

JSON Parsing Options

Android has bundled the `org.json` classes into the SDK since the beginning, for use in parsing JSON. These classes have a DOM-style interface: you hand `JSONObject` a hunk of JSON, and it gives you an in-memory representation of the completely parsed result. This is handy but, like the DOM, a bit of a performance hog.

API Level 11 added `JSONReader`, based on Google's GSON parser, as a "streaming" parser alternative. `JSONReader` is much more reminiscent of the `XmlPullParser`, in that you pull events out of the "reader" and process them. This can have significant performance advantages, particularly in terms of memory consumption, if you do not need the entire JSON data structure. However, this is only available on API Level 11 and higher.

Because `JSONReader` is a bit "late to the party", there has been extensive work on getting other JSON parsers working on Android. Google's GSON is popular, as is Jackson. Jackson offers a few APIs, and the streaming API reportedly works very nicely on Android with top-notch performance.

Using Files with Implicit Intents

Earlier, we saw how to use an implicit `Intent` to, say, view a Web page, given an `https` URL. You can do the same sort of thing with files... though there are issues.

Technically, you can take any `File`, pass it to `Uri.fromFile()`, and get a `Uri` pointing to that file. You can put that `Uri` into an implicit `Intent`, such as one for `ACTION_VIEW`, and pass that `Intent` to `startActivity()`:

```
startActivity(new Intent(Intent.ACTION_VIEW, Uri.fromFile(somethingCool)));
```

However, at best, this only works for files on external storage. Other apps — such as whatever activity handles your `ACTION_VIEW` request — do not have rights to your portion of internal storage or your portion of removable storage. Plus, you have no guarantee that the other app has either the `READ_EXTERNAL_STORAGE` or `WRITE_EXTERNAL_STORAGE` permission (though, if it responded to your `Intent`, it should).

Hence, in Android 7.0, the `file` scheme on a `Uri` is banned, in effect. If you attempt to pass a `file:` `Uri` in an `Intent` that is going to another app, you will crash with a `FileUriExposedException` exception.

(you will face similar issues with putting `file:` `Uri` values on the clipboard in `ClipData` — coverage of the clipboard is later in this book)

This is coming from an updated edition of `StrictMode`. `StrictMode.VmPolicy.Builder` has a `penaltyDeathOnFileUriExposure()` method that triggers the detection of `file:` `Uri` values and the resulting `FileUriExposedException` exceptions. And, it appears that this is pre-configured, much as how `StrictMode` is pre-configured to apply `penaltyDeathOnNetwork()` (the source of your `NetworkOnMainThreadException` crashes).

However, this only kicks in if your `targetSdkVersion` is set to 24 or higher. At that point, you will need to find other ways of getting your content to other apps, such as via a class called `FileProvider`, which is covered later in this book. Or, you can also disable the check by configuring your own `StrictMode.VmPolicy` and skipping `directFileUriExposure()`, though this is not a great solution.

Visit the Trails!

In addition to this chapter, you can learn more about accessing multimedia files via the `MediaStore` and learn more about the impacts of multiple user accounts on tablets.

Tutorial #11 - Adding Simple Content

Now that we have seen how to work with assets, we can start putting them to use, by defining some "help" and "about" HTML files and displaying them in their respective activities.

This is a continuation of the work we did in the previous tutorial.

You can find the results of the previous tutorial and the results of this tutorial in the book's GitHub repository.

Step #1: Adding Some Content

In Android Studio, right-click over the `main` source set directory, choose New > Directory from the context menu, fill in the name `assets` in the dialog, and click OK. This should give you an `app/` module that looks like:

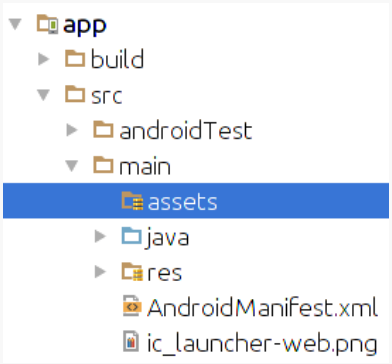

Figure 274: EmPubLite Project, Showing assets/ in main/ of app/

In `assets/`, create a `misc/` sub-folder, by right-clicking over the `assets/` folder and choosing to add a new directory named `misc` (e.g., New > Directory from the Android Studio context menu), giving you something like:

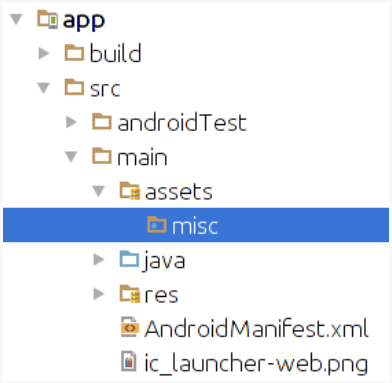

Figure 275: EmPubLite Project, Showing assets/misc/ in main/ of app/

In `assets/misc/`, create two files, `about.html` and `help.html`. In Android Studio, right-click over the `assets/misc/` folder in the project explorer, choose New > File from the context menu, fill in the desired filename in the dialog, and click OK.

The actual HTML content of these two files does not matter, so long as you can tell them apart when looking at them. If you prefer, you can download sample `about.html` and `help.html` files from the application's GitHub repository, via the links.

Step #2: Using SimpleContentFragment

Now, open up `SimpleContentActivity` and replace the stub implementation that we have now with the following Java:

```
package com.commonsware.empublite;

import android.app.Activity;
import android.app.Fragment;
import android.os.Bundle;

public class SimpleContentActivity extends Activity {
  public static final String EXTRA_FILE = "file";

  @Override
  public void onCreate(Bundle savedInstanceState) {
```

```
    super.onCreate(savedInstanceState);

    if (getFragmentManager().findFragmentById(android.R.id.content)==null) {
      String file=getIntent().getStringExtra(EXTRA_FILE);
      Fragment f=SimpleContentFragment.newInstance(file);

      getFragmentManager().beginTransaction()
        .add(android.R.id.content, f).commit();
    }
  }
}
```

(from EmPubLite-AndroidStudio/T11-HelpAbout/EmPubLite/app/src/main/java/com/commonsware/empublite/SimpleContentActivity.java)

If you prefer, you can view this file's contents in your Web browser via this GitHub link.

In `onCreate()`, we follow the standard recipe for defining our fragment if (and only if) we were started new, rather than restarted after a configuration change, by seeing if the fragment already exists. If we do need to add the fragment, we retrieve a string extra from the `Intent` used to launch us (identified as `EXTRA_FILE`), create an instance of `SimpleContentFragment` using that value from the extra, and execute a `FragmentTransaction` to add the `SimpleContentFragment` to our UI.

Step #3: Launching Our Activities, For Real This Time

Now, what remains is to actually supply that `EXTRA_FILE` value, which we are not doing presently when we start up `SimpleContentActivity` from `EmPubLiteActivity`.

Modify `onOptionsItemSelected()` of `EmPubLiteActivity` to look like this:

```
@Override
public boolean onOptionsItemSelected(MenuItem item) {
  switch (item.getItemId()) {
    case R.id.about:
      Intent i = new Intent(this, SimpleContentActivity.class)
        .putExtra(SimpleContentActivity.EXTRA_FILE,
          "file:///android_asset/misc/about.html");
      startActivity(i);

      return(true);
```

```
      case R.id.help:
        i = new Intent(this, SimpleContentActivity.class)
          .putExtra(SimpleContentActivity.EXTRA_FILE,
            "file:///android_asset/misc/help.html");
        startActivity(i);

        return(true);
    }

    return(super.onOptionsItemSelected(item));
  }
```

(from EmPubLite-AndroidStudio/T11-HelpAbout/EmPubLite/app/src/main/java/com/commonsware/empublite/EmPubLiteActivity.java)

You are adding the two `putExtra()` calls in the `R.id.about` and `R.id.help` branches of the `switch` statement. In both cases, we are using a quasi-URL with the prefix `file:///android_asset/`. This points to the root of our project's `assets/` folder. `WebView` knows how to interpret these URLs, to load files out of our assets directly.

Step #4: Getting a Bit More Material

Right now, our action bar on Android 5.0 devices is the one defined by `Theme.Holo.Light.DarkActionBar`. This certainly works. However, it looks a bit out of place, as most of the built-in apps will be using a material theme. So, let's make some minor adjustments to make our app blend in a bit better.

First, we need to add a `res/values-v21/` directory, representing resources that will be used solely on API Level 21+ devices. In Android Studio, right-click over the `res/` directory in your `main/` source set and choose New > "Android resource directory" from the context menu. Choose "values" as the "Resource type". Then, in the list of available qualifiers on the left, click on "Version", then click the ">>" button to the right of that list. This may give you a fairly messed-up dialog, at least in the current version of Android Studio:

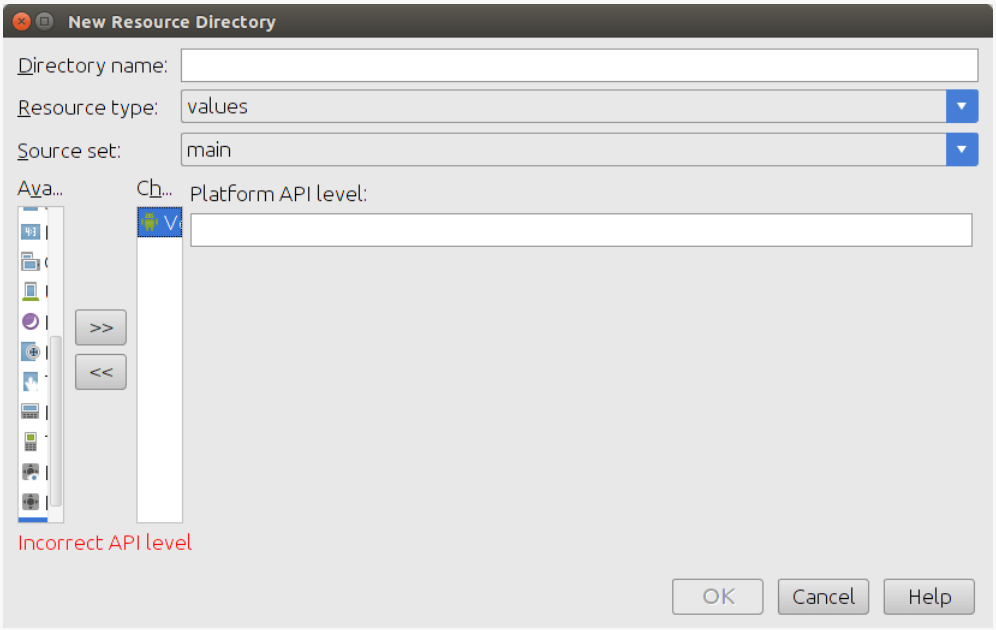

Figure 276: Android Studio New Resource Directory Dialog

Fill in `21` in the "Platform API level" field, then click OK. This should give you an empty `res/values-v21/` directory, as desired.

Then, copy the `styles.xml` file from `res/values/` into `res/values-v21/`. Windows/Linux users can drag `styles.xml` from `res/values/` while holding down the Control key to make a copy. macOS users probably have a similar convention.

Open `res/values-v21/styles.xml` and change the `parent` attribute of our one `style` element to be `android:Theme.Material.Light.DarkActionBar`. Also, add three child elements to the `<style>` element:

```
<resources>

  <!-- Base application theme. -->
  <style name="AppTheme" parent="android:Theme.Material.Light.DarkActionBar">
    <item name="android:colorPrimary">@color/colorPrimary</item>
    <item name="android:colorPrimaryDark">@color/colorPrimaryDark</item>
    <item name="android:colorAccent">@color/colorAccent</item>
  </style>

</resources>
```

(from EmPubLite-AndroidStudio/T11-HelpAbout/EmPubLite/app/src/main/res/values-v21/styles.xml)

These tell `Theme.Material` (and its descendants) to apply our existing color scheme to the theme.

Step #5: Seeing the Results

Now, if you run the application and choose "Help" from the action bar overflow, you will see your help content on-screen:

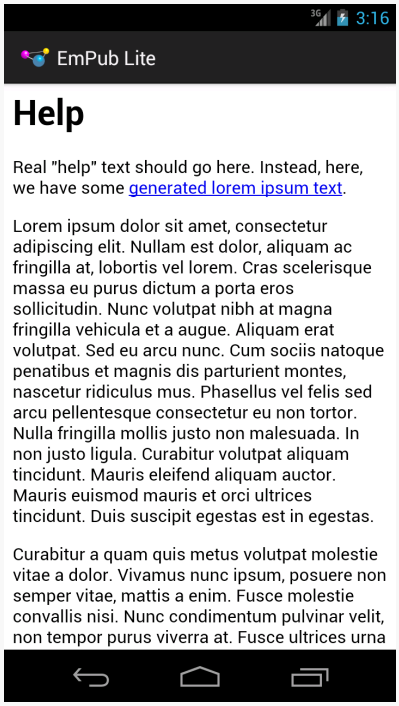

Figure 277: EmPubLite Help Screen

Pressing BACK and choosing "About" from the action bar overflow will bring up your about content:

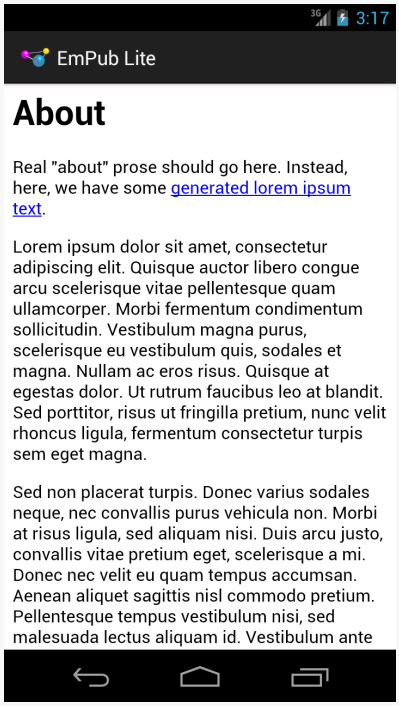

Figure 278: EmPubLite About Screen

However, on an Android 5.0 or higher device or emulator, our action bar will now sport our designated color scheme:

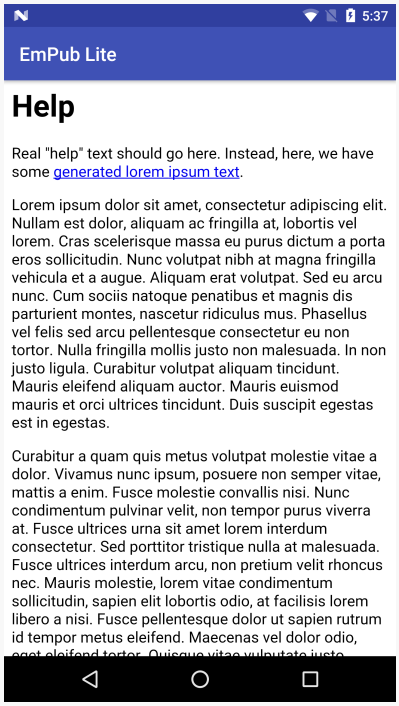

Figure 279: EmPubLite Help Screen on Android 5.1

In Our Next Episode…

… we will display the actual content of our book in our tutorial project.

Tutorial #12 - Displaying the Book

At this point, you are probably wondering when we are *ever* going to have our digital book reader let us read a digital book.

Now, in this tutorial, your patience will be rewarded.

This is a continuation of the work we did in the previous tutorial.

You can find the results of the previous tutorial and the results of this tutorial in the book's GitHub repository.

Note that starting in this tutorial, it is assumed that you know how to add `import` statements as needed as we refer to new classes in existing code, and so the required imports are not always going to be specified.

Step #1: Adding a Book

First, we need a book. Expecting you to write a book as part of this tutorial would seem to be a bit excessive. So, instead, we will use an already-written book: The War of the Worlds, by H. G. Wells, as distributed by Project Gutenberg.

EDITOR'S NOTE: We realize that this choice of book may be seen as offensive by Martians, as it depicts them as warlike invaders with limited immune systems. Please understand that this book is a classic of Western literature and reflects the attitude of the times. If you have any concerns about this material, please contact us at *martians-so-do-not-exist@commonsware.com*.

Download http://misc.commonsware.com/WarOfTheWorlds.zip and unpack its contents (a `book/` directory of files) into your `assets/` folder of your project.

Windows and Linux Android Studio users can drag this `book/` directory into the project and drop it in `assets/` to copy the files to the proper location. You should wind up with `assets/book/` and files inside of there:

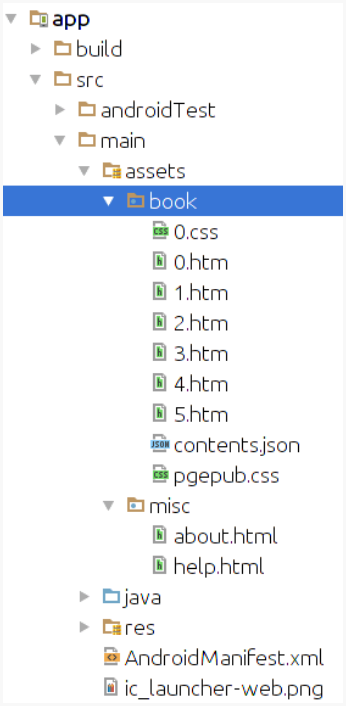

Figure 280: Android Studio Project Explorer, Showing assets/book/

In that directory, you will find some HTML and CSS files with the prose of the book, plus a `contents.json` file with metadata. We will examine this metadata in greater detail in the next section.

Step #2: Creating a ModelFragment

This sample project will use the "model fragment" pattern to hold onto the data about the book to be viewed. The "model fragment" pattern works well for cases where:

- the data is only needed by one activity, not several components, and
- we want to hold onto the data during a configuration change (e.g., screen rotation), so that we do not have to perform some work again to obtain the data

Something has to load that `BookContents`, ideally in the background, since reading an asset and parsing the JSON will take time. Also, something has to hold onto that `BookContents`, so it can be used from `EmPubLiteActivity` and the various chapter fragments in the `ViewPager`.

To that end, we will create a new class, cunningly named `ModelFragment`.

Right-click over the `com.commonsware.empublite` package in your `java/` directory and choose New > Java Class from the context menu. Fill in `ModelFragment` as the name, `android.app.Fragment` as the superclass, and click OK to create the empty class.

Step #3: Defining Our Model

That `contents.json` file contains a bit of metadata about the contents of the book: the book's title and a roster of its "chapters":

```
{
  "title": "The War of the Worlds",
  "chapters": [
    {
      "file": "0.htm",
      "title": "Book One: Chapters 1-9"
    },
    {
      "file": "1.htm",
      "title": "Book One: Chapters 10-14"
    },
    {
      "file": "2.htm",
      "title": "Book One: Chapters 14-17"
    },
    {
      "file": "3.htm",
      "title": "Book Two: Chapters 1-7"
    },
    {
      "file": "4.htm",
      "title": "Book Two: Chapters 7-10"
    },
    {
      "file": "5.htm",
      "title": "Project Gutenberg"
    }
```

```
  ]
}
```

In the case of this book from Project Gutenberg, the `assets/book/` directory contains six HTML files which `EmPubLite` will consider as "chapters", even though each of those HTML files contains multiple chapters from the source material. You are welcome to reorganize that HTML if you wish, updating `contents.json` to match.

We need to load `contents.json` into memory, so `EmPubLite` knows how many chapters to display and where those chapters can be found. We will pour `contents.json` into a `BookContents` model object, leveraging the GSON library that we added to our project in an earlier tutorial.

Right-click over the `com.commonsware.empublite` package in your `java/` directory and choose New > Java Class from the context menu. Fill in `BookContents` as the name and click OK to create the empty class.

Then, replace the contents of that class with the following:

```
package com.commonsware.empublite;

import java.util.List;

public class BookContents {
  List<BookContents.Chapter> chapters;

  int getChapterCount() {
    return(chapters.size());
  }

  String getChapterFile(int position) {
    return(chapters.get(position).file);
  }

  String getChapterTitle(int position) {
    return(chapters.get(position).title);
  }

  static class Chapter {
    String file;
    String title;
  }
}
```

(from EmPubLite-AndroidStudio/T12-Book/EmPubLite/app/src/main/java/com/commonsware/empublite/BookContents.java)

If you prefer, you can view this file's contents in your Web browser via this GitHub link.

Step #4: Examining Our Model

`BookContents` is a GSON interpretation of the JSON structure of `contents.json`. `BookContents` holds onto the `chapters`, as a `List` of `BookContents.Chapter` objects, each of which holds onto its file.

`BookContents` also supplies three accessor methods:

- `getChapterCount()`, to identify the number of chapters (i.e., the size of the `chapters` array in the JSON)
- `getChapterFile()`, to return the relative path within `assets/book/` that represents our "chapter" of HTML
- `getChapterTitle()`, to return the title of this "chapter" of the book

Step #5: Defining Our Event

We will want to load the JSON and create the `BookContents` on a background thread, as we will be performing enough I/O and parsing that we might make our UI a bit sluggish if we do the work on the main application thread. However, we need to let the UI layer (`EmPubLiteActivity` and its `ViewPager`) know when the book is loaded, so it can be poured into the user interface.

We could use an `AsyncTask` for that, notifying the activity in `onPostExecute()`. However, we will need more flexible inter-component communication over time, things that cannot be handled by a simple `AsyncTask`. Hence, we will start using the event bus pattern here, employing greenrobot's EventBus library that we added to our project in a previous tutorial.

With EventBus, we create our own event classes. The one event that we have up front is one to indicate that our book metadata has been loaded and is ready for use, in the form of a `BookContents` object. Hence, in this step of the tutorial, we will define a `BookLoadedEvent` that will be posted when the book is loaded. And, we will have the event hold onto the `BookContents`, to lightly simplify populating the UI later on.

Right-click over the `com.commonsware.empublite` package in your `java/` directory and choose New > Java Class from the context menu. Fill in `BookLoadedEvent` as the name and click OK to create the empty class.

Then, replace the contents of that class with the following:

```
package com.commonsware.empublite;

public class BookLoadedEvent {
  private BookContents contents=null;

  public BookLoadedEvent(BookContents contents) {
    this.contents=contents;
  }

  public BookContents getBook() {
    return(contents);
  }
}
```

(from EmPubLite-AndroidStudio/T12-Book/EmPubLite/app/src/main/java/com/commonsware/empublite/BookLoadedEvent.java)

If you prefer, you can view this file's contents in your Web browser via this GitHub link.

Step #6: Loading Our Model

Now, we need to actually arrange to load the book on a background thread and post our newly-created `BookLoadedEvent`. This is one of the key jobs of our `ModelFragment`: to manage the loading of our activity's model, using background threads.

With that in mind, replace our stub `ModelFragment` implementation with the following:

```
package com.commonsware.empublite;

import android.app.Activity;
import android.app.Fragment;
import android.content.res.AssetManager;
import android.os.Bundle;
import android.os.Process;
import android.util.Log;
import com.google.gson.Gson;
```

```
import org.greenrobot.eventbus.EventBus;
import java.io.BufferedReader;
import java.io.IOException;
import java.io.InputStream;
import java.io.InputStreamReader;
import java.util.concurrent.atomic.AtomicReference;

public class ModelFragment extends Fragment {
  final private AtomicReference<BookContents> contents=
    new AtomicReference<>();

  @Override
  public void onCreate(Bundle savedInstanceState) {
    super.onCreate(savedInstanceState);
    setRetainInstance(true);
  }

  @Override
  public void onAttach(Activity host) {
    super.onAttach(host);

    if (contents.get()==null) {
      new LoadThread(host.getAssets()).start();
    }
  }

  public BookContents getBook() {
    return(contents.get());
  }

  private class LoadThread extends Thread {
    private AssetManager assets=null;

    LoadThread(AssetManager assets) {
      super();

      this.assets=assets;
    }

    @Override
    public void run() {
      Process.setThreadPriority(Process.THREAD_PRIORITY_BACKGROUND);
      Gson gson=new Gson();

      try {
        InputStream is=assets.open("book/contents.json");
        BufferedReader reader=
          new BufferedReader(new InputStreamReader(is));
```

```
        contents.set(gson.fromJson(reader, BookContents.class));

        EventBus.getDefault().post(new BookLoadedEvent(getBook()));
      }
      catch (IOException e) {
        Log.e(getClass().getSimpleName(), "Exception parsing JSON", e);
      }
    }
  }
}
```

(from EmPubLite-AndroidStudio/T12-Book/EmPubLite/app/src/main/java/com/commonsware/empublite/ModelFragment.java)

If you prefer, you can view this file's contents in your Web browser via this GitHub link.

In `onCreate()`, we call `setRetainInstance(true)`, to tell the framework to keep this fragment despite a configuration change, just passing it to the new activity created as a result of that configuration change.

In `onAttach()`, if we do not already have our `BookContents` object, we fork a `LoadThread` to populate it, and we cannot readily get at an `AssetManager` until we are attached to the hosting activity. This is why we are not forking `LoadThread` in `onCreate()`. You may see this method name appear with strikethrough formatting. `onAttach()` taking a `Context` as a parameter was added in API Level 23, and `onAttach()` taking a `Activity` as a parameter was deprecated. However, our `minSdkVersion` is lower than 23, so we need to use the older callback method.

`LoadThread` takes the `AssetManager` as a parameter, stashing it in a field in the `LoadThread` constructor.

Then, in the `run()` method that is called on the background thread, we call `setThreadPriority()` to drop the thread's priority to that of a background thread. This reduces how much we compete with the main application thread for CPU time. Then, we read in the JSON using GSON to create the `BookContents` instance. GSON automatically de-serializes our JSON into the `BookContents` and `BookContents.Chapter` instances, given that we are telling the `fromJson()` method that it is to be loading an instance of a `BookContents` object. Finally, we `post()` a `BookLoadedEvent` to the default `EventBus`.

The `BookContents` is wrapped in an `AtomicReference`, in case the main application thread tries to get the `BookContents` at the same time our background thread tries to

set that field's value. Using an `AtomicReference` handles our thread synchronization for us.

The `open()` method on `AssetManager` could throw an `IOException`. Normally, this indicates a development-time bug (e.g., we failed to actually set up the `book/contents.json` file), which is why we log the message to Logcat. A production-grade book reader should also `post()` an `EventBus` event to allow the UI layer to let the user know that we could not load the book. As it stands, the book reader will remain stuck on the `ProgressBar` forever in case of this sort of problem. Augmenting the tutorial in this way is left as an exercise for the reader.

Note that the `LoadThread` implementation has a pair of references to `Process`. In this case, this is `android.os.Process`, not `java.lang.Process`. Since `java.lang.Process` is automatically imported, if you fail to import `android.os.Process`, you will see errors about how `THREAD_PRIORITY_BACKGROUND` and `setThreadPriority()` are not defined. Since we are not using `java.lang.Process` in this class, having the import to `android.os.Process` (as shown in the code listing above) resolves this conflict.

Step #7: Registering for Events

Right now, our `BookLoadedEvent` will be posted... and ignored, as nothing in the application is set up to watch for such events. Our `EmPubLiteActivity` needs to know about these events, and the first step to accomplishing that is to have it register for events in general with the `EventBus`.

Add the following two methods to `EmPubLiteActivity`:

```
@Override
  public void onStart() {
    super.onStart();
    EventBus.getDefault().register(this);
  }

  @Override
  public void onStop() {
    EventBus.getDefault().unregister(this);
    super.onStop();
  }
```

These simply register the activity with the `EventBus` while it is in the foreground.

Step #8: Adapting the Content

Before we can use the `BookContents`, we need to update `ContentsAdapter` to display the prose on the screen.

First, add a `BookContents` data member to `ContentsAdapter`:

```
  final BookContents contents;
```

(from EmPubLite-AndroidStudio/T12-Book/EmPubLite/app/src/main/java/com/commonsware/empublite/ContentsAdapter.java)

Then, add the `BookContents` parameter to the constructor, assigning it to the new data member:

```
  public ContentsAdapter(Activity ctxt, BookContents contents) {
    super(ctxt.getFragmentManager());

    this.contents=contents;
  }
```

(from EmPubLite-AndroidStudio/T12-Book/EmPubLite/app/src/main/java/com/commonsware/empublite/ContentsAdapter.java)

Next, update `getCount()` to use the `getChapterCount()` of our `BookContents`:

```
  @Override
  public int getCount() {
    return(contents.getChapterCount());
  }
```

(from EmPubLite-AndroidStudio/T12-Book/EmPubLite/app/src/main/java/com/commonsware/empublite/ContentsAdapter.java)

Then, modify `getItem()` to retrieve the relative path for a given chapter from the `BookContents` and create a `SimpleContentFragment` on the complete `file:///android_asset` path to the file in question:

```
  @Override
  public Fragment getItem(int position) {
    String path=contents.getChapterFile(position);

    return(SimpleContentFragment.newInstance("file:///android_asset/book/"
      + path));
  }
```

(from EmPubLite-AndroidStudio/T12-Book/EmPubLite/app/src/main/java/com/commonsware/empublite/ContentsAdapter.java)

Note that you may need to change the parameter name in the `getItem()` declaration to be `position`, as it may be another value (e.g., `arg0`).

Finally, add `getPageTitle()`, pulling our tab title from the chapter title:

```
@Override
public CharSequence getPageTitle(int position) {
  return(contents.getChapterTitle(position));
}
```

(from EmPubLite-AndroidStudio/T12-Book/EmPubLite/app/src/main/java/com/commonsware/empublite/ContentsAdapter.java)

Step #9: Showing the Content When Loaded

Now, we can actually add the logic to display the book once it is loaded.

Create a `setupPager()` method on `EmPubLiteActivity` as follows:

```
private void setupPager(BookContents contents) {
  adapter=new ContentsAdapter(this, contents);
  pager.setAdapter(adapter);

  MaterialTabs tabs=(MaterialTabs)findViewById(R.id.tabs);
  tabs.setViewPager(pager);
}
```

(from EmPubLite-AndroidStudio/T12-Book/EmPubLite/app/src/main/java/com/commonsware/empublite/EmPubLiteActivity.java)

The contents of this method are almost identical to some lines in `onCreate()` – we have just moved them to a separate method. Remove those duplicate lines from `onCreate()`, so you have:

```
@Override
protected void onCreate(Bundle savedInstanceState) {
  super.onCreate(savedInstanceState);
  setContentView(R.layout.main);

  pager=(ViewPager)findViewById(R.id.pager);
}
```

Then, add the following `onBookLoaded()` method to `EmPubLiteActivity`:

```
@SuppressWarnings("unused")
@Subscribe(threadMode =ThreadMode.MAIN)
public void onBookLoaded(BookLoadedEvent event) {
```

```
    setupPager(event.getBook());
  }
```

(from EmPubLite-AndroidStudio/T12-Book/EmPubLite/app/src/main/java/com/commonsware/empublite/EmPubLiteActivity.java)

This tells `EventBus` that if a `BookLoadedEvent` is posted, we are interested in it, and it should be delivered to our `onBookLoaded()` method on the main application thread. This method looks like it is unused, because it will be called using reflection by the EventBus, and the IDE does not know that. The `@SuppressWarnings("unused")` annotation indicates that this method is used.

Step #10: Attaching our ModelFragment

We also need to add some code to set up the `ModelFragment` — it will not magically appear on its own. So, the first time we create an `EmPubLiteActivity`, we want to create our `ModelFragment`. To do that, define a static data member named `MODEL` in `EmPubLiteActivity`:

```
  private static final String MODEL="model";
```

(from EmPubLite-AndroidStudio/T12-Book/EmPubLite/app/src/main/java/com/commonsware/empublite/EmPubLiteActivity.java)

Then, update the `onStart()` method in `EmPubLiteActivity` to see if we already have the fragment before creating one:

```
@Override
public void onStart() {
  super.onStart();
  EventBus.getDefault().register(this);

  if (adapter==null) {
    ModelFragment mfrag=
        (ModelFragment)getFragmentManager().findFragmentByTag(MODEL);

    if (mfrag == null) {
      getFragmentManager().beginTransaction()
          .add(new ModelFragment(), MODEL).commit();
    }
  }
}
```

If you run the result in a device or emulator, you will see the book content appear:

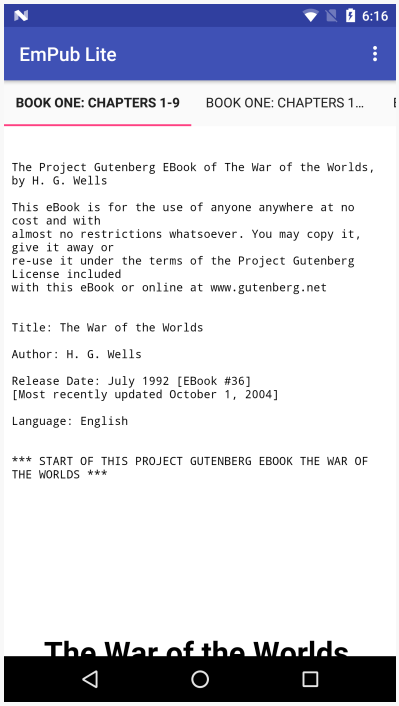

Figure 281: EmPubLite, With Content

Swiping left and right will take you to the other portions of the book.

Step #11: Showing the Content After a Configuration Change

While you can see the book contents now, if you try rotating the screen, the book contents will not appear. That is because the `ModelFragment` has already loaded the contents (so the `BookLoadedEvent` has passed), but we have no logic in `EmPubLiteActivity` to populate the book by other means.

To do that, simply add an `else if` clause to the `if` in `onStart()`, to get the book contents over to `setupPager()` if they are ready:

```
@Override
public void onStart() {
  super.onStart();
  EventBus.getDefault().register(this);

  if (adapter==null) {
    ModelFragment mfrag=
```

```
      (ModelFragment)getFragmentManager().findFragmentByTag(MODEL);

    if (mfrag==null) {
      getFragmentManager().beginTransaction()
        .add(new ModelFragment(), MODEL).commit();
    }
    else if (mfrag.getBook()!=null) {
      setupPager(mfrag.getBook());
    }
  }
}
```

(from EmPubLite-AndroidStudio/T12-Book/EmPubLite/app/src/main/java/com/commonsware/empublite/EmPubLiteActivity.java)

Now, if you run the sample and rotate the screen (e.g., Ctrl-Right on the Windows/Linux emulator), the book will appear in either case.

Step #12: Setting Up StrictMode

Since we are now starting to do disk I/O, particularly aiming to have it done on background threads, it would be a good idea to configure `StrictMode`, so it will complain if we fail in our quest and accidentally do this I/O on the main application thread.

Add the following method to `EmPubLiteActivity`:

```
private void setupStrictMode() {
  StrictMode.ThreadPolicy.Builder builder=
    new StrictMode.ThreadPolicy.Builder()
      .detectAll()
      .penaltyLog();

  if (BuildConfig.DEBUG) {
    builder.penaltyFlashScreen();
  }

  StrictMode.setThreadPolicy(builder.build());
}
```

(from EmPubLite-AndroidStudio/T12-Book/EmPubLite/app/src/main/java/com/commonsware/empublite/EmPubLiteActivity.java)

Here, we create a `StrictMode.ThreadPolicy.Builder`, configured to detect all violations on the main application thread, logging them to Logcat. In addition, if we are in a `DEBUG` build, we will flash a red border around the screen.

Note, though, that this red border will appear even if *we* do not make any mistakes. Unfortunately, Google engineers do not check the framework code for these sorts of violations, leading to some bugs that we as app developers cannot resolve. Those will be reported as `StrictMode` violations, just as if we had made the mistakes ourselves.

At the present time, this tutorial does not trigger any `StrictMode` violations, and so the red border flash should not appear. However, changes in newer versions of Android, or newer versions of the support libraries, might change that, at which time the red flashes will point out that the author of this book has to fix the tutorials.

Then, just after `super.onCreate()` in the `onCreate()` method in `EmPubLiteActivity`, add in a call to the new `setupStrictMode()` method. This will give you an `onCreate()` method that looks like:

```
@Override
protected void onCreate(Bundle savedInstanceState) {
  super.onCreate(savedInstanceState);
  setContentView(R.layout.main);

  setupStrictMode();
  pager=(ViewPager)findViewById(R.id.pager);
}
```

(from EmPubLite-AndroidStudio/T12-Book/EmPubLite/app/src/main/java/com/commonsware/empublite/EmPubLiteActivity.java)

In Our Next Episode…

… we will allow the user to manipulate some preferences in our tutorial project.

Using Preferences

Android has many different ways for you to store data for long-term use by your activity. The simplest ones to use are `SharedPreferences` and simple files.

Android allows activities and applications to keep preferences, in the form of key/value pairs (akin to a `Map`), that will hang around between invocations of an activity. As the name suggests, the primary purpose is for you to store user-specified configuration details, such as the last feed the user looked at in your feed reader, or what sort order to use by default on a list, or whatever. Of course, you can store in the preferences whatever you like, so long as it is keyed by a `String` and has a primitive value (`boolean`, `String`, etc.)

Preferences can either be for a single activity or shared among all activities in an application. Other components, such as services, also can work with shared preferences.

Getting What You Want

To get access to the preferences, you have three APIs to choose from:

- `getPreferences()` from within your `Activity`, to access activity-specific preferences
- `getSharedPreferences()` from within your `Activity` (or other application `Context`), to access application-level preferences
- `getDefaultSharedPreferences()`, on `PreferenceManager`, to get the shared preferences that work in concert with Android's overall preference framework

The first two take a security mode parameter. The right answer here is `MODE_PRIVATE`, so no other applications can access the file. The `getSharedPreferences()` method also takes a name of a set of preferences; `getPreferences()` effectively calls `getSharedPreferences()` with the activity's class name as the preference set name. The `getDefaultSharedPreferences()` method takes the `Context` for the preferences (e.g., your `Activity`).

All of those methods return an instance of `SharedPreferences`, which offers a series of getters to access named preferences, returning a suitably-typed result (e.g., `getBoolean()` to return a boolean preference). The getters also take a default value, which is returned if there is no preference set under the specified key.

Unless you have a good reason to do otherwise, you are best served using the third option above — `getDefaultSharedPreferences()` — as that will give you the `SharedPreferences` object that works with a `PreferenceActivity` by default, as will be described later in this chapter.

Stating Your Preference

Given the appropriate `SharedPreferences` object, you can use `edit()` to get an "editor" for the preferences. This object has a set of setters that mirror the getters on the parent `SharedPreferences` object. It also has:

1. `remove()` to get rid of a single named preference
2. `clear()` to get rid of all preferences
3. `apply()` or `commit()` to persist your changes made via the editor

The last one is important — if you modify preferences via the editor and fail to save the changes, those changes will evaporate once the editor goes out of scope. `commit()` is a blocking call, while `apply()` works asynchronously. Ideally, use `apply()` where possible, though it was only added in Android 2.3, so it may not be available to you if you are aiming to support earlier versions of Android than that.

Conversely, since the preferences object supports live changes, if one part of your application (say, an activity) modifies shared preferences, another part of your application (say, a service) will have access to the changed value immediately.

Collecting Preferences with PreferenceFragment

Some "preferences" will be collected as part of the natural use of your user interface. For example, if you have a `SeekBar` to control a zoom level, you might elect to record the `SeekBar` position in `SharedPreferences`, so you can restore the user's last zoom level later on.

However, in many cases, we have various settings that we would like the user to be able to configure but are not something that the user would configure elsewhere in our UI. You could roll your own UI to collect preferences in bulk from the user. On the whole, this is a bad idea. Instead, use preference XML resources and a `PreferenceFragment`.

Why?

One of the common complaints about Android developers is that they lack discipline, not following any standards or conventions inherent in the platform. For other operating systems, the device manufacturer might prevent you from distributing apps that violate their human interface guidelines. With Android, that is not the case — but this is not a blanket permission to do whatever you want. Where there is a standard or convention, please follow it unless you have a *clear* reason not to, so that users will feel more comfortable with your app and their device.

Using a `PreferenceFragment` for collecting preferences is one such convention.

The linchpin to the preferences framework and `PreferenceFragment` is yet another set of XML data structures. You can describe your application's preferences in XML files stored in your project's `res/xml/` directory. Given that, Android can present a UI for manipulating those preferences, one which matches what you see in the Settings app. The user's choices are then stored in the `SharedPreferences` that you get back from `getDefaultSharedPreferences()`.

This can be seen in the `Prefs/Fragment` sample project.

Showing the Current Values

This project's main activity hosts a `TableLayout`, into which we will load the values of five preferences:

```
<?xml version="1.0" encoding="utf-8"?>
<TableLayout xmlns:android="http://schemas.android.com/apk/res/android"
  android:layout_width="match_parent"
  android:layout_height="match_parent">

  <TableRow>

    <TextView
      style="@style/label"
      android:text="@string/checkbox"/>

    <TextView
      android:id="@+id/checkbox"
      style="@style/value"/>
  </TableRow>

  <TableRow>

    <TextView
      style="@style/label"
      android:text="@string/ringtone"/>

    <TextView
      android:id="@+id/ringtone"
      style="@style/value"/>
  </TableRow>

  <TableRow>

    <TextView
      style="@style/label"
      android:text="@string/text"/>

    <TextView
      android:id="@+id/text"
      style="@style/value"/>
  </TableRow>

  <TableRow>

    <TextView
      style="@style/label"
      android:text="@string/list"/>

    <TextView
      android:id="@+id/list"
      style="@style/value"/>
  </TableRow>
```

```
</TableLayout>
```

(from Prefs/Fragment/app/src/main/res/layout/content.xml)

The above layout is used by `PreferenceContentsFragment`, which populates the right-hand column of `TextView` widgets at runtime in `onResume()`, pulling the values from the default `SharedPreferences` for our application:

```
package com.commonsware.android.preffrag;

import android.app.Fragment;
import android.content.SharedPreferences;
import android.os.Bundle;
import android.preference.PreferenceManager;
import android.view.LayoutInflater;
import android.view.View;
import android.view.ViewGroup;
import android.widget.TextView;

public class PreferenceContentsFragment extends Fragment {
  private TextView checkbox=null;
  private TextView ringtone=null;
  private TextView text=null;
  private TextView list=null;

  @Override
  public View onCreateView(LayoutInflater inflater, ViewGroup parent,
                           Bundle savedInstanceState) {
    View result=inflater.inflate(R.layout.content, parent, false);

    checkbox=(TextView)result.findViewById(R.id.checkbox);
    ringtone=(TextView)result.findViewById(R.id.ringtone);
    text=(TextView)result.findViewById(R.id.text);
    list=(TextView)result.findViewById(R.id.list);

    return(result);
  }

  @Override
  public void onResume() {
    super.onResume();

    SharedPreferences prefs=
        PreferenceManager.getDefaultSharedPreferences(getActivity());

    checkbox.setText(Boolean.valueOf(prefs.getBoolean("checkbox", false)).toString());
    ringtone.setText(prefs.getString("ringtone", "<unset>"));
    text.setText(prefs.getString("text", "<unset>"));
    list.setText(prefs.getString("list", "<unset>"));
  }
}
```

(from Prefs/Fragment/app/src/main/java/com/commonsware/android/preffrag/PreferenceContentsFragment.java)

The main activity, `FragmentsDemo`, simply loads `res/layout/main.xml`, which contains a `<fragment>` element pointing at `PreferenceContentsFragment`. It also defines an options menu, which we will examine later in this section.

The result is an activity showing the default values of the preferences when it is first run, since we have not set any values yet:

Figure 282: Activity Showing Preference Values

Defining Your Preferences

First, you need to tell Android what preferences you are trying to collect from the user.

To do this, you will need to add a `res/xml/` directory to your project, if one does not already exist. Then, for your `PreferenceFragment`, you will define one of these XML resource files. The root element of this XML file will be `<PreferenceScreen>`, and it will contain child elements, one per preference.

In the sample project, we have one such file, `res/xml/preferences.xml`:

```
<PreferenceScreen xmlns:android="http://schemas.android.com/apk/res/android">

  <CheckBoxPreference
    android:key="checkbox"
    android:summary="@string/pref1summary"
    android:title="@string/pref1title"/>

  <RingtonePreference
    android:key="ringtone"
    android:showDefault="true"
    android:showSilent="true"
    android:summary="@string/pref2summary"
    android:title="@string/pref2title"/>

  <EditTextPreference
    android:dialogTitle="@string/dialogtitle"
    android:key="text"
    android:summary="@string/pref3summary"
    android:title="@string/pref3title"/>

  <ListPreference
    android:dialogTitle="@string/listdialogtitle"
    android:entries="@array/cities"
    android:entryValues="@array/airport_codes"
    android:key="list"
    android:summary="@string/pref4summary"
    android:title="@string/pref4title"/>

</PreferenceScreen>
```

(from Prefs/Fragment/app/src/main/res/xml/preferences.xml)

Each preference element has two attributes at minimum:

1. `android:key`, which is the key you use to look up the value in the `SharedPreferences` object via methods like `getInt()`
2. `android:title`, which is a few words identifying this preference to the user

You may also wish to consider having `android:summary`, which is a short sentence explaining what the user is to supply for this preference.

There are lots of other attributes that are common to all preference elements, and there are more types of preference elements than the ones that we used in the preference XML shown above. We will examine more preference elements later in this chapter.

Creating Your PreferenceFragment

Preference XML, on API Level 11 and higher, is loaded by an implementation of `PreferenceFragment`. The mission of `PreferenceFragment` is to call `addPreferencesFromResource()` in `onCreate()`, supplying the resource ID of the preference XML to load (e.g., `R.xml.preference2`). That fragment, in turn, can be loaded up by a simple `Activity`.

In fact, the fragment is so short, you could even make it be a static class inside the activity, as is done in the sample app. The activity that collects the preferences, `EditPreferences`, has a `Prefs` static subclass of `PreferenceFragment`:

```
package com.commonsware.android.preffrag;

import android.app.Activity;
import android.os.Bundle;
import android.preference.PreferenceFragment;

public class EditPreferences extends Activity {
  @Override
  public void onCreate(Bundle savedInstanceState) {
    super.onCreate(savedInstanceState);

    if (getFragmentManager().findFragmentById(android.R.id.content)==null) {
      getFragmentManager().beginTransaction()
          .add(android.R.id.content,
              new Prefs()).commit();
    }
  }

  public static class Prefs extends PreferenceFragment {
    @Override
    public void onCreate(Bundle savedInstanceState) {
      super.onCreate(savedInstanceState);

      addPreferencesFromResource(R.xml.preferences);
    }
  }
}
```

(from Prefs/Fragment/app/src/main/java/com/commonsware/android/preffrag/EditPreferences.java)

The only thing that `Prefs` does is call the inherited `addPreferencesFromResource()` in its `onCreate()` method, supplying the ID of the preference XML. All

`EditPreferences` does is show the fragment, in this case using a `FragmentTransaction`.

The Results

An action bar item in `MainActivity` starts up the `EditPreferences` activity. If you click that from the overflow, you will see the UI created from your XML by means of the `PreferenceFragment`:

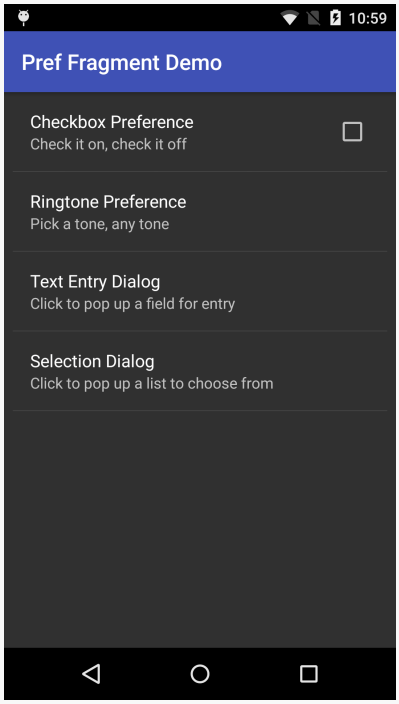

Figure 283: Activity Collecting Preference Values

If you make a change, such as tapping on the checkbox, and press BACK to return to the original activity, you will see the resulting change in the preference values themselves:

Figure 284: Original Activity, Showing Revised Preference Value

Android Studio's Preferences Editor

If you open up a preference XML resource in Android Studio, you will be given an editor that is reminiscent of the layout resource editor. You will have two sub-tabs: "Text" with the XML and "Design" with a drag-and-drop UI:

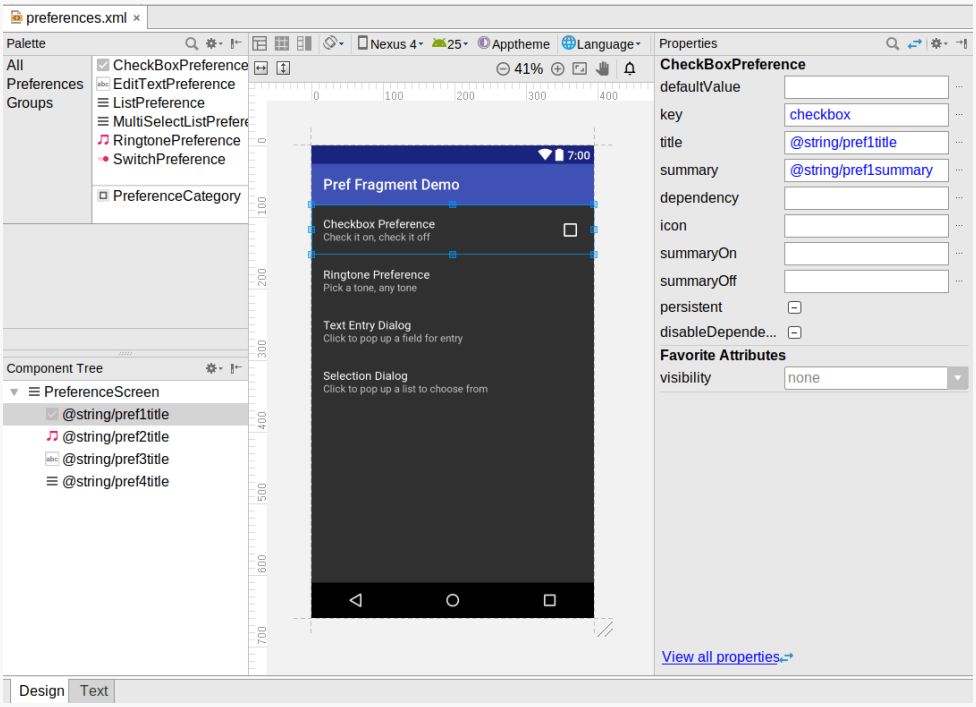

Figure 285: Android Studio Preferences Editor

The drag-and-drop editor UI works akin to its layout resource editor counterpart. You can drag a preference from the Palette into either the preview area or into the Component Tree to add it to the resource. For any selected preference, the Attributes pane allows you to modify attributes, either from the default short list of popular properties or the full list of properties that you get from clicking "View all properties".

Types of Preferences

There are a variety of subclasses of `Preference` in the Android SDK for use with `PreferenceActivity`. This section will outline the major ones. Later in the book we will examine how to create your own custom `Preference` classes.

CheckBoxPreference and SwitchPreference

The sample application shown above a `CheckBoxPreference`. A `CheckBoxPreference` is an "inline" preference, in that the widget the user interacts with (in this case, a `CheckBox`) is part of the preference screen itself, rather than contained in a separate dialog.

`SwitchPreference` is functionally equivalent to `CheckBoxPreference`, insofar as both collect `boolean` values from the user. The difference is that `SwitchPreference` uses a `Switch` widget that the user slides left and right to toggle between "on" and "off" states. Also note that `SwitchPreference` was added in API Level 14 and therefore will not be available to older Android versions.

EditTextPreference

`EditTextPreference`, when tapped by the user, pops up a dialog that contains an `EditText` widget. You can configure this widget via attributes on the `<EditTextPreference>` element — in addition to standard preference attributes like `android:key`, you can include any attribute understood by `EditText`, such as `android:inputType`.

The value stored in the `SharedPreferences` is a string.

The sample app has an `EditTextPreference`:

```
<EditTextPreference
  android:dialogTitle="@string/dialogtitle"
  android:key="text"
  android:summary="@string/pref3summary"
  android:title="@string/pref3title"/>
```

(from Prefs/Fragment/app/src/main/res/xml/preferences.xml)

When the user taps on it in the `PreferenceFragment`, the user will see a dialog where they can fill in a value, or edit an existing value if they provided one previously:

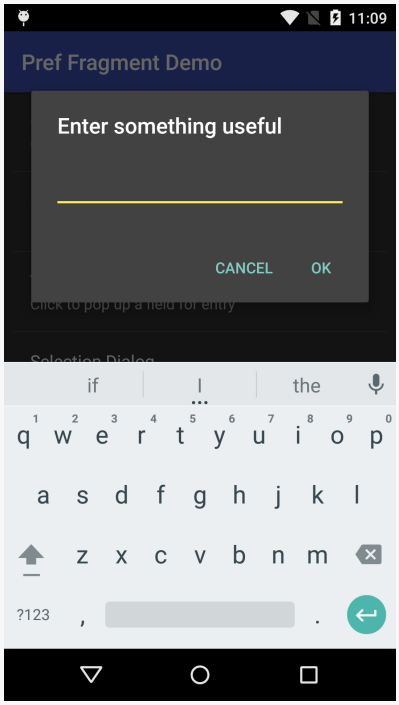

Figure 286: EditTextPreference UI

RingtonePreference

`RingtonePreference` pops up a dialog with a list of ringtones installed on the device or emulator. However, bear in mind that older emulator images may not have any pre-installed ringtones.

In addition to the standard preference attributes, you can include `android:showDefault`, indicating that the list should contain a "Default ringtone" option. If the user chooses this ringtone, they are effectively choosing the same ringtone that they have set up for incoming phone calls.

You can also use `android:showSilent`, which allows the user to choose a "Silence" pseudo-ringtone, to indicate not to play any ringtone.

The sample app has a `RingtonePreference`:

```
<RingtonePreference
  android:key="ringtone"
  android:showDefault="true"
  android:showSilent="true"
```

```
    android:summary="@string/pref2summary"
    android:title="@string/pref2title"/>
```

(from Prefs/Fragment/app/src/main/res/xml/preferences.xml)

When the user taps on it in the `PreferenceFragment`, the user will see a roster of ringtones, along with "Default" and "None" options, since we opted into those:

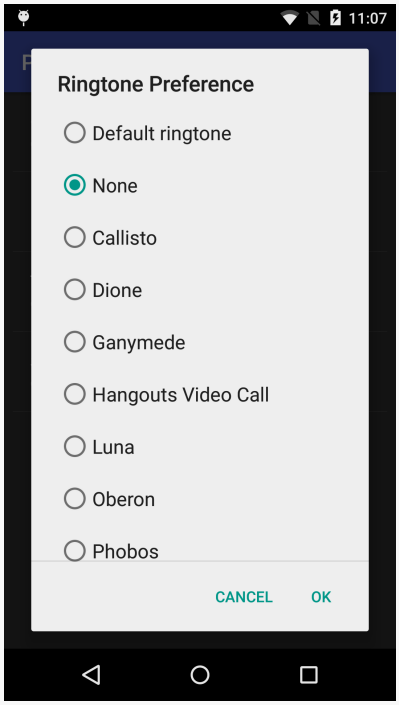

Figure 287: RingtonePreference UI

The value stored in the `SharedPreferences` is a string, specifically the string representation of a `Uri` pointing to a `ContentProvider` that can serve up the ringtone for playback. The use of `ContentProvider` will be covered in a later chapter, and playing back media like ringtones will be covered in another later chapter.

ListPreference and MultiSelectListPreference

Visually, a `ListPreference` looks just like `RingtonePreference`, except that *you* control what goes into the list. You do this by specifying a pair of `string-array` resources in your preference XML.

String resources hold individual strings; string array resources hold a collection of strings. Typically, you will find string array resources in `res/values/arrays.xml` and

related resource sets for translation. The `<string-array>` element has the `name` attribute to identify the resource, along with child `<item>` elements for the individual strings in the array.

So, our sample app has a pair of `<string-array>` resources in `res/values/arrays.xml`:

```
<?xml version="1.0" encoding="utf-8"?>
<resources>
  <string-array name="cities">
    <item>Philadelphia</item>
    <item>Pittsburgh</item>
    <item>Allentown/Bethlehem</item>
    <item>Erie</item>
    <item>Reading</item>
    <item>Scranton</item>
    <item>Lancaster</item>
    <item>Altoona</item>
    <item>Harrisburg</item>
  </string-array>
  <string-array name="airport_codes">
    <item>PHL</item>
    <item>PIT</item>
    <item>ABE</item>
    <item>ERI</item>
    <item>RDG</item>
    <item>AVP</item>
    <item>LNS</item>
    <item>AOO</item>
    <item>MDT</item>
  </string-array>
</resources>
```

(from Prefs/Fragment/app/src/main/res/values/arrays.xml)

Here, the actual strings are written in-line. They could just as easily be references to string resource (e.g., `<item>@string/philly</item>`). For user-facing strings, like those in the `cities` array, having them as string resources may make it easier for you to manage your translations.

The sample app then uses those arrays in a `ListPreference`:

```
  <ListPreference
    android:dialogTitle="@string/listdialogtitle"
    android:entries="@array/cities"
    android:entryValues="@array/airport_codes"
```

```
    android:key="list"
    android:summary="@string/pref4summary"
    android:title="@string/pref4title"/>
```

(from Prefs/Fragment/app/src/main/res/xml/preferences.xml)

This then allows the user to choose a city, when the user taps on this preference in the `PreferenceFragment`:

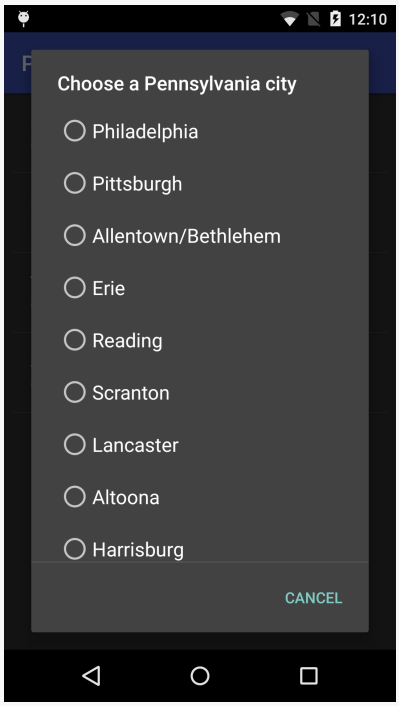

Figure 288: ListPreference UI

However, when the user chooses a city by name (e.g., Philadelphia), what is stored in the `SharedPreferences` is the *corresponding* airport code (e.g., PHL).

`MultiSelectListPreference` works much the same way, except:

- The list contains checkboxes, not radio buttons
- The user can check multiple items
- The result is stored in a "string set" in the `SharedPreferences`, retrieved via `getStringSet()`
- It is only available on API Level 11 and higher

We will see `MultiSelectListPreference` in action later in the book.

Tutorial #13 - Using Some Preferences

Now that we have the core reading functionality working, we can start to add other features for the user.

One common thing in Android applications is to collect preferences from the user, tailoring the way the app behaves. In the case of `EmPubLite`, we will initially track two preferences:

- Whether the user wants to return to the book on the same chapter (page in the `ViewPager`) that they were on when they last were reading the book
- Whether the user wants us to keep the screen on, so they do not have to keep tapping the screen to prevent Android's automatic sleep mode from kicking in

In this tutorial, we will collect and use these two preferences.

This is a continuation of the work we did in the previous tutorial.

You can find the results of the previous tutorial and the results of this tutorial in the book's GitHub repository.

Step #1: Defining the Preference XML Files

We need an XML resource file to define what preferences we wish to collect.

First, add four new `<string>` elements to `res/values/strings.xml`:

```
<string name="lastposition_title">Save Last Position</string>
<string name="lastposition_summary">Save the last chapter you were viewing and open
up on that chapter when re-opening the app</string>
```

```
<string name="keepscreenon_summary">Keep the screen powered on while the reader is in
the foreground</string>
<string name="keepscreenon_title">Keep Screen On</string>
```

Next, right click over `res/` in your project, and choose New > "Android resource directory" from the context menu. Change the "Resource type" drop-down to be "xml", then click OK to create the directory.

Then, right-click over your new `res/xml/` directory and choose New > "XML resource file" from the context menu. Fill in `pref_display.xml` in the "New XML Resource File" dialog, then click OK to create the file.

This will open up in a preference screen editor, with "Design" and "Text" sub-tabs:

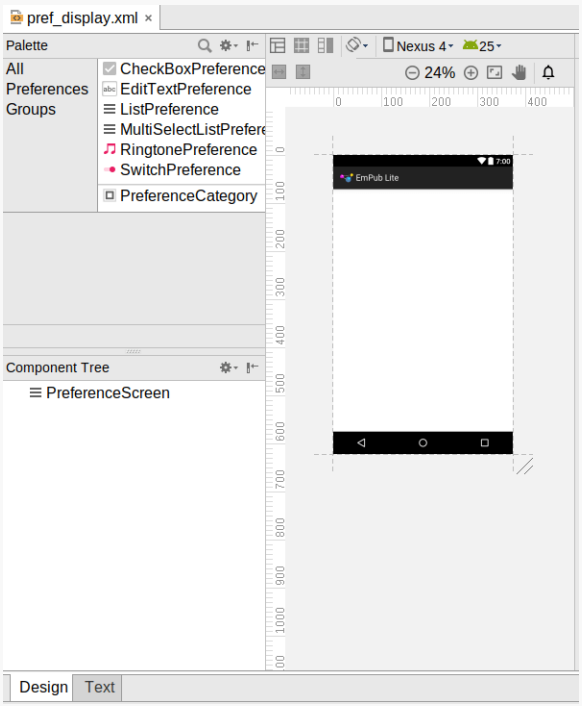

Figure 289: Android Studio Preference Screen Editor, As Initially Launched

Drag a `CheckBoxPreference` from the Palette into the preview area. Then, in the Attributes pane, set the key to `saveLastPosition`, set the title to `@string/lastposition_title`, and set the summary to `@string/lastposition_summary`:

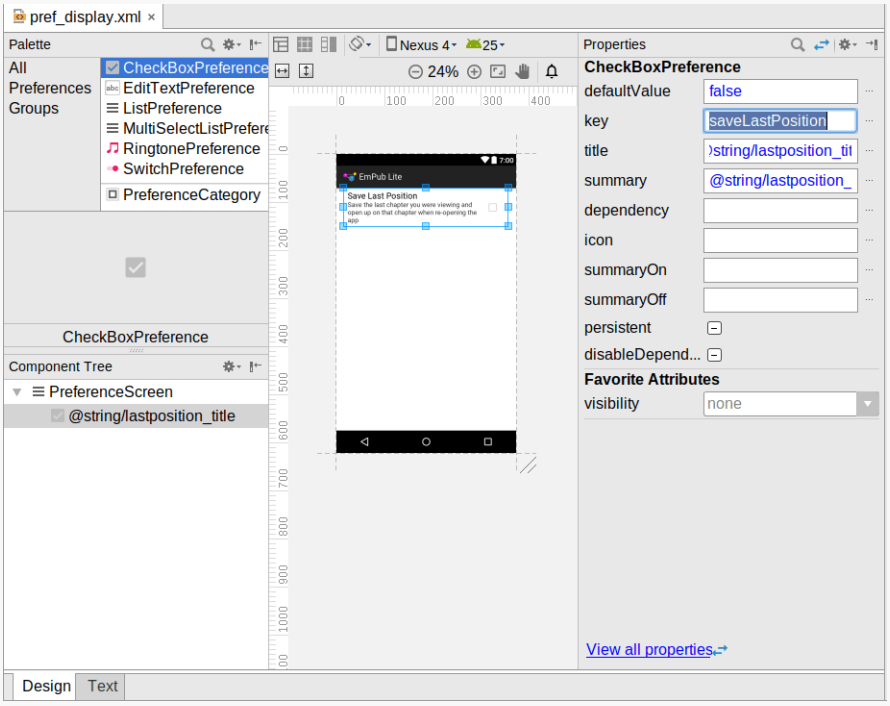

Figure 290: Android Studio Preference Screen Editor, After First Preference

Next, drag another `CheckBoxPreference` from the Palette into the preview area. Then, in the Attributes pane for this newly-added preference, set the key to `keepScreenOn`, set the title to `@string/keepscreenon_title`, and set the summary to `@string/keepscreenon_summary`:

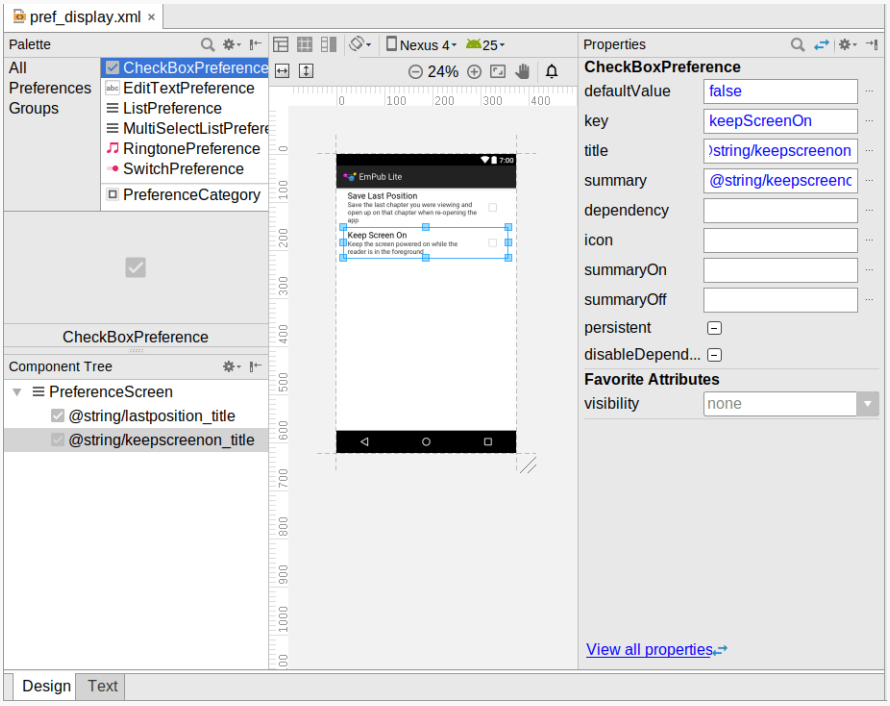

Figure 291: Android Studio Preference Screen Editor, After Second Preference

If you look at the XML in the "Text" sub-tab, you should see that it resembles:

```
<?xml version="1.0" encoding="utf-8"?>
<PreferenceScreen
  xmlns:android="http://schemas.android.com/apk/res/android">

  <CheckBoxPreference
    android:defaultValue="false"
    android:title="@string/lastposition_title"
    android:key="saveLastPosition"
    android:summary="@string/lastposition_summary" />
  <CheckBoxPreference
    android:defaultValue="false"
    android:title="@string/keepscreenon_title"
    android:key="keepScreenOn"
    android:summary="@string/keepscreenon_summary" />
</PreferenceScreen>
```

(from EmPubLite-AndroidStudio/T13-Prefs/EmPubLite/app/src/main/res/xml/pref_display.xml)

Step #2: Creating Our Preference Activity

We will eventually load that preference XML into a `PreferenceFragment`. We could use a `PreferenceActivity` for that, but we do not have enough preferences to warrant a full master/detail setup. Instead, we can just display the `PreferenceFragment` in a regular `Activity`, named `Preferences`, using a static inner class implementation of a `PreferenceFragment`, named `Display`.

Right-click over the `com.commonsware.empublite` package in your `java/` directory and choose New > Activity > Empty Activity from the context menu. Set the activity name to be `Preferences` and uncheck all the checkboxes. Then click Finish to add the activity to the project.

In the `Preferences` class that is created, replace the current implementation with the following:

```
package com.commonsware.empublite;

import android.app.Activity;
import android.os.Bundle;
import android.preference.PreferenceFragment;

public class Preferences extends Activity {
  @Override
  protected void onCreate(Bundle savedInstanceState) {
    super.onCreate(savedInstanceState);

    if (getFragmentManager().findFragmentById(android.R.id.content)==null) {
      getFragmentManager()
        .beginTransaction()
        .add(android.R.id.content, new Display())
        .commit();
    }
  }

  public static class Display extends PreferenceFragment {
    @Override
    public void onCreate(Bundle savedInstanceState) {
      super.onCreate(savedInstanceState);
      addPreferencesFromResource(R.xml.pref_display);
    }
  }
}
```

(from EmPubLite-AndroidStudio/T13-Prefs/EmPubLite/app/src/main/java/com/commonsware/empublite/Preferences.java)

If you prefer, you can view this file's contents in your Web browser via this GitHub link.

Step #3: Adding To Our Action Bar

Of course, having this activity does us no good if we cannot start it up, so we need to add another hook to our action bar configuration for that.

First, add a `settings` string resource, with a value of `Settings`:

```
<string name="settings">Settings</string>
```

Then, right-click over the `res/` directory of your `app/` module, and choose New > Vector Asset from the context menu. Click the Icon button, search for `settings`, and choose the "settings" icon, creating an `ic_settings_black_24dp` icon.

Click Next, then Finish.

Finally, add the following XML element to `res/menu/options.xml` as the first child of the `<menu>` root element:

```
  <item
    android:id="@+id/settings"
    android:icon="@drawable/ic_settings_black_24dp"
    android:showAsAction="never"
    android:title="@string/settings">
  </item>
```

(from EmPubLite-AndroidStudio/T13-Prefs/EmPubLite/app/src/main/res/menu/options.xml)

Step #4: Launching the Preference Activity

The only thing yet needed to allow the user to get to the preferences is to add another `case` to the `switch()` statement in `onOptionsItemSelected()` of `EmPubLiteActivity`:

```
  @Override
  public boolean onOptionsItemSelected(MenuItem item) {
    switch (item.getItemId()) {
      case R.id.about:
        Intent i = new Intent(this, SimpleContentActivity.class)
          .putExtra(SimpleContentActivity.EXTRA_FILE,
```

```
          "file:///android_asset/misc/about.html");
      startActivity(i);

      return(true);

    case R.id.help:
      i = new Intent(this, SimpleContentActivity.class)
        .putExtra(SimpleContentActivity.EXTRA_FILE,
          "file:///android_asset/misc/help.html");
      startActivity(i);

      return(true);

    case R.id.settings:
      startActivity(new Intent(this, Preferences.class));

      return(true);
  }

  return(super.onOptionsItemSelected(item));
}
```

(from EmPubLite-AndroidStudio/T13-Prefs/EmPubLite/app/src/main/java/com/commonsware/empublite/EmPubLiteActivity.java)

Now, if you run this in an emulator or device, you will see the new option in the action bar overflow:

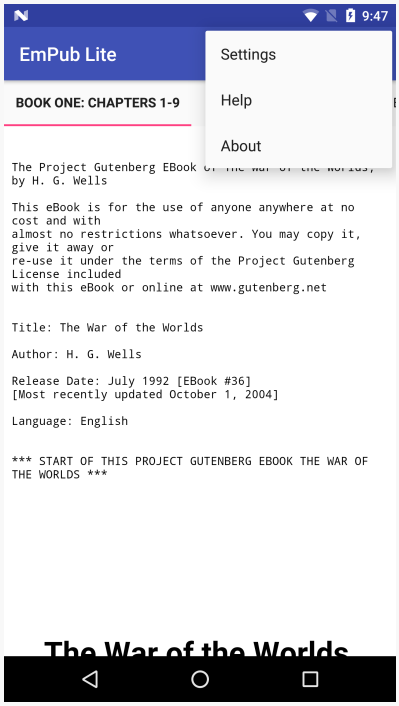

Figure 292: EmPubLite, With Revised Action Bar

Choosing the “Settings” option brings up our two preferences:

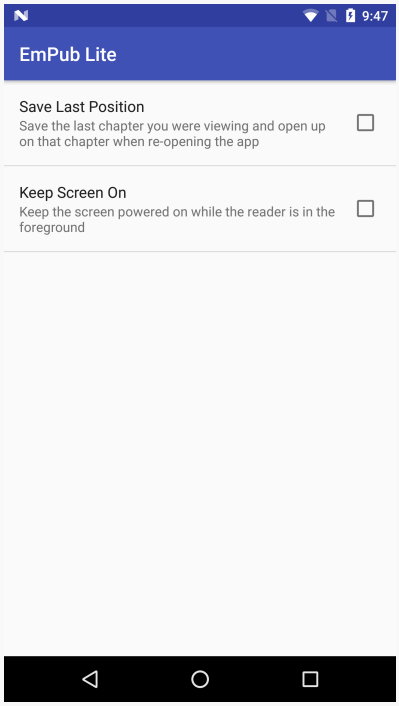

Figure 293: Our Preferences

Step #5: Loading the Preferences

Now, we need to actually arrange to load the preferences on a background thread. As noted, this will be handled by our `ModelFragment`, much as it handles the loading of the book contents.

First, add a private data member named `prefs`, that is an `AtomicReference` to a `SharedPreferences`, to `ModelFragment`:

```
final private AtomicReference<SharedPreferences> prefs=
  new AtomicReference<>();
```

(from EmPubLite-AndroidStudio/T13-Prefs/EmPubLite/app/src/main/java/com/commonsware/empublite/ModelFragment.java)

Then, add a `getPrefs()` method to `ModelFragment` that returns the `prefs` value:

```
public SharedPreferences getPrefs() {
  return(prefs.get());
}
```

(from EmPubLite-AndroidStudio/T13-Prefs/EmPubLite/app/src/main/java/com/commonsware/empublite/ModelFragment.java)

Next, revise `LoadThread` to:

- Replace the `assets` data member with a `ctxt` data member of type `Context`
- Take in a `Context` in the constructor, instead of an `AssetManager` (this way, even if for some strange reason our original activity is destroyed and recreated while we are loading the preferences, we will not be leaking the original activity)
- Save the application context (from `getApplicationContext()` on `Context`) in a data member, instead of an `AssetManager`
- Call `getAssets()` on that `Context` in `run()`, instead of using the former `AssetManager`
- Also retrieve the `SharedPreferences` in `run()`

```
private class LoadThread extends Thread {
  final private Context ctxt;

  LoadThread(Context ctxt) {
    super();

    this.ctxt=ctxt.getApplicationContext();
  }

  @Override
  public void run() {
    prefs.set(PreferenceManager.getDefaultSharedPreferences(ctxt));

    Process.setThreadPriority(Process.THREAD_PRIORITY_BACKGROUND);
    Gson gson=new Gson();

    try {
      InputStream is=ctxt.getAssets().open("book/contents.json");
      BufferedReader reader=
        new BufferedReader(new InputStreamReader(is));

      contents.set(gson.fromJson(reader, BookContents.class));

      EventBus.getDefault().post(new BookLoadedEvent(getBook()));
    }
    catch (IOException e) {
      Log.e(getClass().getSimpleName(), "Exception parsing JSON", e);
    }
  }
}
```

(from EmPubLite-AndroidStudio/T13-Prefs/EmPubLite/app/src/main/java/com/commonsware/empublite/ModelFragment.java)

This has our `LoadThread` load both the `SharedPreferences` and the `BookContents`, and do so in a known order (`SharedPreferences` first).

You will need to modify `onAttach()` to just pass in the `Activity` to the `LoadThread` constructor:

```
  @Override
  public void onAttach(Activity host) {
    super.onAttach(host);

    if (contents.get()==null) {
      new LoadThread(host).start();
    }
  }
```

(from EmPubLite-AndroidStudio/T13-Prefs/EmPubLite/app/src/main/java/com/commonsware/empublite/ModelFragment.java)

The resulting `ModelFragment` should look like:

```
package com.commonsware.empublite;

import android.app.Activity;
import android.app.Fragment;
import android.content.Context;
import android.content.SharedPreferences;
import android.content.res.AssetManager;
import android.os.Bundle;
import android.os.Process;
import android.preference.PreferenceManager;
import android.util.Log;
import com.google.gson.Gson;
import org.greenrobot.eventbus.EventBus;
import java.io.BufferedReader;
import java.io.IOException;
import java.io.InputStream;
import java.io.InputStreamReader;
import java.util.concurrent.atomic.AtomicReference;

public class ModelFragment extends Fragment {
  final private AtomicReference<BookContents> contents=
    new AtomicReference<>();
  final private AtomicReference<SharedPreferences> prefs=
    new AtomicReference<>();

  @Override
  public void onCreate(Bundle savedInstanceState) {
    super.onCreate(savedInstanceState);
```

```
    setRetainInstance(true);
  }

  @Override
  public void onAttach(Activity host) {
    super.onAttach(host);

    if (contents.get()==null) {
      new LoadThread(host).start();
    }
  }

  public BookContents getBook() {
    return(contents.get());
  }

  public SharedPreferences getPrefs() {
    return(prefs.get());
  }

  private class LoadThread extends Thread {
    final private Context ctxt;

    LoadThread(Context ctxt) {
      super();

      this.ctxt=ctxt.getApplicationContext();
    }

    @Override
    public void run() {
      prefs.set(PreferenceManager.getDefaultSharedPreferences(ctxt));

      Process.setThreadPriority(Process.THREAD_PRIORITY_BACKGROUND);
      Gson gson=new Gson();

      try {
        InputStream is=ctxt.getAssets().open("book/contents.json");
        BufferedReader reader=
          new BufferedReader(new InputStreamReader(is));

        contents.set(gson.fromJson(reader, BookContents.class));

        EventBus.getDefault().post(new BookLoadedEvent(getBook()));
      }
      catch (IOException e) {
        Log.e(getClass().getSimpleName(), "Exception parsing JSON", e);
      }
```

```
    }
  }
}
```

(from EmPubLite-AndroidStudio/T13-Prefs/EmPubLite/app/src/main/java/com/commonsware/empublite/ModelFragment.java)

Step #6: Saving the Last-Read Position

One preference is to restore our current page in the `ViewPager` when the user later re-opens the app. To make that work, we need to start saving the current page as the user leaves the app. And, we may as well use our freshly-minted `SharedPreferences` to store this value.

We need a key under which we will store this value in the `SharedPreferences`, so add a new static data member to `EmPubLiteActivity`:

```
private static final String PREF_LAST_POSITION="lastPosition";
```

We are also going to need access to our `ModelFragment` from outside of `onResume()` in `EmPubLiteActivity`. Add a `ModelFragment` data member named `mfrag`:

```
  private ModelFragment mfrag=null;
```

(from EmPubLite-AndroidStudio/T13-Prefs/EmPubLite/app/src/main/java/com/commonsware/empublite/EmPubLiteActivity.java)

Then, modify `onStart()` to refer to the `mfrag` data member, replacing the former `mfrag` local variable:

```
  @Override
  public void onStart() {
    super.onStart();
    EventBus.getDefault().register(this);

    if (adapter==null) {
      mfrag=(ModelFragment)getFragmentManager().findFragmentByTag(MODEL);

      if (mfrag==null) {
        mfrag=new ModelFragment();

        getFragmentManager().beginTransaction()
          .add(mfrag, MODEL).commit();
      }
      else if (mfrag.getBook()!=null) {
        setupPager(mfrag.getBook());
      }
```

```
    }
  }
```

Next, update `onStop()` on `EmPubLiteActivity` to track the page of the `ViewPager` that the user is on at the point in time when `onStop()` is called:

```
@Override
public void onStop() {
  EventBus.getDefault().unregister(this);

  if (mfrag.getPrefs()!=null) {
    int position=pager.getCurrentItem();

    mfrag.getPrefs().edit().putInt(PREF_LAST_POSITION, position)
      .apply();
  }

  super.onStop();
}
```

(from EmPubLite-AndroidStudio/T13-Prefs/EmPubLite/app/src/main/java/com/commonsware/empublite/EmPubLiteActivity.java)

Here, we check to see that we have the `SharedPreferences` loaded — odds are that we do, but we cannot be certain. If we do have access to the `SharedPreferences`, we find out the current position within the `ViewPager` via `getCurrentItem()` (e.g., `0` for the first page). We then obtain a `SharedPreferences.Editor` and use it to save this position value in the `SharedPreferences`, keyed as `PREF_LAST_POSITION`, using `apply()` to persist the changes.

Step #7: Restoring the Last-Read Position

Now that we are saving this position data, we can start to use it.

Our preference XML has our key to the "Save Last Position" preference, but we need it in Java code as well, so add another static data member to `EmPubLiteActivity`:

```
private static final String PREF_SAVE_LAST_POSITION="saveLastPosition";
```

Add the following lines to the end of `setupPager()` in `EmPubLiteActivity`:

```
    SharedPreferences prefs=mfrag.getPrefs();

    if (prefs != null) {
      if (prefs.getBoolean(PREF_SAVE_LAST_POSITION, false)) {
```

```
      pager.setCurrentItem(prefs.getInt(PREF_LAST_POSITION, 0));
    }
  }
```

Here, we check to see if the user has enabled having us restore the last-saved position (defaulting to `false`). If the user has, we retrieve the last-saved position (defaulting to `0`, or the first page), and call `setCurrentItem()` on the `ViewPager` to shift to that particular page.

If you run this in a device or emulator, check the "Save Last Position" preference checkbox, flip ahead a couple of chapters, exit the app via the BACK button, and go back into the app, you will see that you are taken back to the chapter you were last reading.

Step #8: Keeping the Screen On

Our other preference is whether or not the screen should stay on, without user input, while we are reading the book. The bare-bones implementation of this requires just two lines of additional code.

First, we need to define another static data member on `EmPubLiteActivity`, this time with the key for our keep-screen-on preference:

```
private static final String PREF_KEEP_SCREEN_ON="keepScreenOn";
```

Then, add one more line to `setupPager()` in `EmPubLiteActivity`, inside of the `if` block:

```
pager.setKeepScreenOn(prefs.getBoolean(PREF_KEEP_SCREEN_ON, false));
```

This will give you:

```
  private void setupPager(BookContents contents) {
    adapter=new ContentsAdapter(this, contents);
    pager.setAdapter(adapter);

    MaterialTabs tabs=(MaterialTabs)findViewById(R.id.tabs);
    tabs.setViewPager(pager);

    SharedPreferences prefs=mfrag.getPrefs();

    if (prefs!=null) {
      if (prefs.getBoolean(PREF_SAVE_LAST_POSITION, false)) {
```

```
      pager.setCurrentItem(prefs.getInt(PREF_LAST_POSITION, 0));
    }

    pager.setKeepScreenOn(prefs.getBoolean(PREF_KEEP_SCREEN_ON, false));
  }
}
```

(from EmPubLite-AndroidStudio/T13-Prefs/EmPubLite/app/src/main/java/com/commonsware/empublite/EmPubLiteActivity.java)

`setKeepScreenOn()`, called on any `View`, will keep the screen lit and active without continuous user input, so long as that `View` is on the screen.

This approach is somewhat limited, in that we are only setting this during the call to `setupPager()`. If the user changes the preference value, that change would only take effect when the activity was restarted (e.g., user rotates the screen, user exits the app via BACK and returns later).

The simplest way for us to have this take more immediate effect is to realize that `EmPubLiteActivity` will be paused and stopped when the `Preferences` activity is on the screen, and will be started and resumed when the user is done adjusting preferences. So, we can simply augment `onStart()` to also update the screen-on setting:

```
@Override
public void onStart() {
  super.onStart();
  EventBus.getDefault().register(this);

  if (adapter==null) {
    mfrag=(ModelFragment)getFragmentManager().findFragmentByTag(MODEL);

    if (mfrag==null) {
      mfrag=new ModelFragment();

      getFragmentManager().beginTransaction()
        .add(mfrag, MODEL).commit();
    }
    else if (mfrag.getBook()!=null) {
      setupPager(mfrag.getBook());
    }
  }

  if (mfrag.getPrefs()!=null) {
    pager.setKeepScreenOn(mfrag.getPrefs()
      .getBoolean(PREF_KEEP_SCREEN_ON, false));
```

```
    }
  }
```

(from EmPubLite-AndroidStudio/T13-Prefs/EmPubLite/app/src/main/java/com/commonsware/empublite/EmPubLiteActivity.java)

Of course, we may not *have* the `SharedPreferences` yet, when the app is first starting up, so we avoid making any changes in that case.

If you run this on a device (note: *not* an emulator), you can play with this preference and see the changes in the screen's behavior.

In Our Next Episode…

… we will allow the user to write, save, and delete notes for the currently-viewed chapter, using a database.

SQLite Databases

Besides `SharedPreferences` and your own file structures, the third primary means of persisting data locally on Android is via SQLite. For many applications, SQLite is the app's backbone, whether it is used directly or via some third-party wrapper.

This chapter will focus on how you can directly work with SQLite to store relational data.

Introducing SQLite

SQLite is a very popular embedded database, as it combines a clean SQL interface with a very small memory footprint and decent speed. Moreover, it is public domain, so everyone can use it. Lots of firms (Adobe, Apple, Google, Symbian) and open source projects (Mozilla, PHP, Python) all ship products with SQLite.

For Android, SQLite is "baked into" the Android runtime, so every Android application can create SQLite databases. Since SQLite uses a SQL interface, it is fairly straightforward to use for people with experience in other SQL-based databases. However, its native API is not JDBC, and JDBC might be too much overhead for a memory-limited device like a phone, anyway. Hence, Android programmers have a different API to learn — the good news being is that it is not that difficult.

This chapter will cover the basics of SQLite use in the context of working on Android. It by no means is a thorough coverage of SQLite as a whole. If you want to learn more about SQLite, the SQLite Web site may help.

Thinking About Schemas

SQLite is a typical relational database, containing tables (themselves consisting of rows and columns), indexes, and so on. Your application will need its own set of tables and so forth for holding whatever data you wish to hold. This structure is generally referred to as a "schema".

It is likely that your schema will need to change over time. You might add new tables or columns in support of new features. Or, you might significantly reorganize your data structure and wind up dropping some tables while moving the data into new ones.

As a result, when you ship an update to your application to your users, not only will your Java code change, but the *expectations* of that Java code will change as well, with respect to what your database schema will look like. Version 1 of your app will use your original schema, but by the time you ship, say, version 5 of the app, you might need an adjusted schema.

Android has facilities to assist you with handling changing database schemas, mostly centered around the `SQLiteOpenHelper` class.

Start with a Helper

`SQLiteOpenHelper` is designed to consolidate your code related to two very common problems:

1. What happens the very first time when your app is run on a device after it is installed? At this point, we do not yet have a database, and so you will need to create your tables, indexes, starter data, and so on.
2. What happens the very first time when an upgraded version of your app is run on a device, where the upgraded version is expecting a newer database schema? Your database will still be on the old schema from the older edition of the app. You will need to have a chance to alter the database schema to match the needs of the rest of your app.

`SQLiteOpenHelper` wraps up the logic to create and upgrade a database, per your specifications, as needed by your application. You will need to create a custom subclass of `SQLiteOpenHelper`, implementing three methods at minimum:

1. The constructor, chaining upward to the `SQLiteOpenHelper` constructor. This takes the `Context` (e.g., an `Activity`), the name of the database, an optional cursor factory (typically, just pass `null`), and an integer representing the version of the database schema you are using (typically start at `1` and increment from there).
2. `onCreate()`, called when there is no database and your app needs one, which passes you a `SQLiteDatabase` object, pointing at a newly-created database, that you use to populate with tables and initial data, as appropriate.
3. `onUpgrade()`, called when the schema version you are seeking does not match the schema version of the database, which passes you a `SQLiteDatabase` object and the old and new version numbers, so you can figure out how best to convert the database from the old schema to the new one.

To see how all this SQLite stuff works in practice, we will examine the Database/ConstantsROWID sample application. This application pulls a bunch of gravitational constants from the `SensorManager` class, puts them in a database table, displays them in a `ListFragment`, and allows the user to add new ones via the action bar.

First, we need a `SQLiteOpenHelper` subclass, here named `DatabaseHelper`.

The `DatabaseHelper` constructor chains to the superclass and supplies the name of the database (held in a `DATABASE_NAME` static data member) and the version number of our database schema (held in `SCHEMA`):

```
public class DatabaseHelper extends SQLiteOpenHelper {
  private static final String DATABASE_NAME="constants.db";
  private static final int SCHEMA=1;
  static final String TITLE="title";
  static final String VALUE="value";
  static final String TABLE="constants";

  public DatabaseHelper(Context context) {
    super(context, DATABASE_NAME, null, SCHEMA);
  }
```

(from Database/ConstantsROWID/app/src/main/java/com/commonsware/android/constants/DatabaseHelper.java)

We also need an `onCreate()` method, which will be called and passed a `SQLiteDatabase` object when a database needs to be newly created. Below you will see the `DatabaseHelper` implementation of `onCreate()`, though we will get into how it is using the `SQLiteDatabase` object more later in this chapter:

```
@Override
public void onCreate(SQLiteDatabase db) {
  db.execSQL("CREATE TABLE constants (title TEXT, value REAL);");

  ContentValues cv=new ContentValues();

  cv.put(TITLE, "Gravity, Death Star I");
  cv.put(VALUE, SensorManager.GRAVITY_DEATH_STAR_I);
  db.insert(TABLE, TITLE, cv);

  cv.put(TITLE, "Gravity, Earth");
  cv.put(VALUE, SensorManager.GRAVITY_EARTH);
  db.insert(TABLE, TITLE, cv);

  cv.put(TITLE, "Gravity, Jupiter");
  cv.put(VALUE, SensorManager.GRAVITY_JUPITER);
  db.insert(TABLE, TITLE, cv);

  cv.put(TITLE, "Gravity, Mars");
  cv.put(VALUE, SensorManager.GRAVITY_MARS);
  db.insert(TABLE, TITLE, cv);

  cv.put(TITLE, "Gravity, Mercury");
  cv.put(VALUE, SensorManager.GRAVITY_MERCURY);
  db.insert(TABLE, TITLE, cv);

  cv.put(TITLE, "Gravity, Moon");
  cv.put(VALUE, SensorManager.GRAVITY_MOON);
  db.insert(TABLE, TITLE, cv);

  cv.put(TITLE, "Gravity, Neptune");
  cv.put(VALUE, SensorManager.GRAVITY_NEPTUNE);
  db.insert(TABLE, TITLE, cv);

  cv.put(TITLE, "Gravity, Pluto");
  cv.put(VALUE, SensorManager.GRAVITY_PLUTO);
  db.insert(TABLE, TITLE, cv);

  cv.put(TITLE, "Gravity, Saturn");
  cv.put(VALUE, SensorManager.GRAVITY_SATURN);
  db.insert(TABLE, TITLE, cv);

  cv.put(TITLE, "Gravity, Sun");
  cv.put(VALUE, SensorManager.GRAVITY_SUN);
  db.insert(TABLE, TITLE, cv);

  cv.put(TITLE, "Gravity, The Island");
  cv.put(VALUE, SensorManager.GRAVITY_THE_ISLAND);
```

```
    db.insert(TABLE, TITLE, cv);

    cv.put(TITLE, "Gravity, Uranus");
    cv.put(VALUE, SensorManager.GRAVITY_URANUS);
    db.insert(TABLE, TITLE, cv);

    cv.put(TITLE, "Gravity, Venus");
    cv.put(VALUE, SensorManager.GRAVITY_VENUS);
    db.insert(TABLE, TITLE, cv);
  }
```

(from Database/ConstantsROWID/app/src/main/java/com/commonsware/android/constants/DatabaseHelper.java)

Suffice it to say for the moment that it is creating a `constants` table and inserting several rows into it, all wrapped in a transaction.

We also need `onUpgrade()`... even though it should never be called right now:

```
@Override
public void onUpgrade(SQLiteDatabase db, int oldVersion,
                      int newVersion) {
  throw new RuntimeException("How did we get here?");
}
```

(from Database/ConstantsROWID/app/src/main/java/com/commonsware/android/constants/DatabaseHelper.java)

After all, right now, we only have one version of our schema (`1`) and therefore will have no need to upgrade. If, in the future, we change `SCHEMA` to a higher value (e.g., `2`), and we upgrade our app on a device that had previously been run with our earlier schema, *then* we will be called with `onUpgrade()`. We are passed the old and new schema versions, so we know what needs to be upgraded.

Bear in mind that users do not necessarily have to take on each of your application updates, and so you might find that a user skipped a schema version:

- You release an app on Monday, with schema version `1`
- A user installs your app on Tuesday and runs it, creating a database via `onCreate()`
- You release an upgraded app on Wednesday, with schema version `2`
- You release yet another upgrade on Thursday, with schema version `3`
- The user installs your upgrade, now needing a schema version `3` database instead of the version `1` presently on the device, triggering a call to `onUpgrade()`

There are two other methods you can elect to override in your `SQLiteOpenHelper`, if you feel the need:

- You can override `onOpen()`, to get control when somebody opens this database. Usually, this is not required.
- Android 3.0 introduced `onDowngrade()`, which will be called if the code requests an older schema than what is in the database presently. This is the converse of `onUpgrade()` — if your version numbers differ, one of these two methods will be invoked. Since normally you are moving forward with updates, you can usually skip `onDowngrade()`.

Employing Your Helper

To use your `SQLiteOpenHelper` subclass, create and hold onto an instance of it. Then, when you need a `SQLiteDatabase` object to do queries or data modifications, ask your `SQLiteOpenHelper` to `getReadableDatabase()` or `getWritableDatabase()`, depending upon whether or not you will be changing its contents.

For example, the `ConstantsFragment` from the sample app creates a `DatabaseHelper` instance in `onViewCreated()` and holds onto it in a data member:

```
      db=new DatabaseHelper(getActivity());
```

(from Database/ConstantsROWID/app/src/main/java/com/commonsware/android/constants/ConstantsFragment.java)

When you are done with the database (e.g., your activity is being closed), simply call `close()` on your `SQLiteOpenHelper` to release your connection, as `ConstantsFragment` does (among other things) in `onDestroy()`:

```
@Override
public void onDestroy() {
  if (task!=null) {
    task.cancel(false);
  }

  ((CursorAdapter)getListAdapter()).getCursor().close();
  db.close();

  super.onDestroy();
}
```

(from Database/ConstantsROWID/app/src/main/java/com/commonsware/android/constants/ConstantsFragment.java)

(we will explore those “other things” in a bit)

Where to Hold a Helper

For trivial apps, like the one profiled in this chapter, holding a `SQLiteOpenHelper` in a data member of your one-and-only activity is fine.

If, however, you have multiple components — such as multiple activities – all needing to use the database, you are much better served having a *singleton instance* of your `SQLiteOpenHelper`, compared to having each activity have its own instance.

The reason is threading.

You really should do your database I/O on background threads. Opening a database is cheap, but working with it (queries, inserts, etc.) is not. The `SQLiteDatabase` object managed by `SQLiteOpenHelper` is thread-safe... so long as all threads are using the same instance.

For singleton objects that depend upon a `Context`, like `SQLiteOpenHelper`, rather than create the object using a garden-variety `Context` like an `Activity`, you really should create it with an `Application`. There is a singleton instance of a `Context`, in the form of the `Application` subclass, created in your process moments after it is started. You can retrieve this singleton by calling `getApplicationContext()` on any other `Context`. The advantage of using `Application` is memory leaks: if you put a `SQLiteOpenHelper` in a singleton, and use, say, an `Activity` to create it, then the `Activity` might not be able to be garbage-collected, because the `SQLiteOpenHelper` keeps a strong reference to it. Since `Application` is itself a singleton (and, hence, is "pre-leaked", so to speak), the risks of a memory leak diminish significantly.

So, instead of:

```
db=new DatabaseHelper(getActivity());
```

in a fragment, with `db` as a data member, you might have:

```
db=new DatabaseHelper(getActivity().getApplicationContext());
```

with `db` as a static data member, shared by multiple activities or other components.

Getting Data Out

One popular thing to do with a database is to get data out of it. Android has a few ways you can execute a query on a `SQLiteDatabase` (from your `SQLiteOpenHelper`),

along with some classes, like `CursorAdapter`, to help you use the results you get back.

Your Query Options

In most cases, your simplest option for executing a query is to call `rawQuery()` on the `SQLiteDatabase`. This takes two parameters:

- A SQL `SELECT` statement (or anything else that returns a result set), optionally with `?` characters in the `WHERE` clause (or `ORDER BY` or similar clauses) representing parameters to be bound at runtime
- An optional `String` array of the parameters to be used to replace the `?` characters in the query

If you do not use the `?` position parameter syntax in your query, you are welcome to pass `null` as the second parameter to `rawQuery()`.

The nice thing about `rawQuery()` is that any valid SQL syntax works, so long as it returns a result set. You are welcome to use joins, sub-selects, and so on without issue.

There are two other query options — `query()` and `SQLiteQueryBuilder`. These both build up a SQL `SELECT` statement from its component parts (e.g., name of the table to query, `WHERE` clause and positional parameters). These are more cumbersome to use, particularly with complex `SELECT` statements. Mostly, they would be used in cases where, for one reason or another, you do not know the precise query at compile time and find it easier to use these facilities to construct the query from parts at runtime. Some developers will do this to avoid duplicating values, by defining constants for things like table names and column names.

For example, `ConstantsFragment` has a private inner class named `BaseTask` which has a `doQuery()` method that uses `query()`:

```
abstract private class BaseTask<T> extends AsyncTask<T, Void, Cursor> {
  @Override
  public void onPostExecute(Cursor result) {
    ((CursorAdapter)getListAdapter()).changeCursor(result);
    current=result;
    task=null;
  }

  Cursor doQuery() {
```

```
    Cursor result=
        db
            .getReadableDatabase()
            .query(DatabaseHelper.TABLE,
                new String[] {"ROWID AS _id",
                              DatabaseHelper.TITLE,
                              DatabaseHelper.VALUE},
                null, null, null, null, DatabaseHelper.TITLE);

    result.getCount();

    return(result);
  }
}
```

(from Database/ConstantsROWID/app/src/main/java/com/commonsware/android/constants/ConstantsFragment.java)

Do not concatenate your own `WHERE` clause, though. Let the `?` positional parameters handle that for you, as the work they do to escape your apostrophes, quotation marks, and the like also helps to defend against SQL injection attacks. In this particular case, we do not have a `WHERE` clause.

If that `ROWID AS _id` piece looks a bit odd, we will see why that is in the query a bit later in this chapter.

What Is a Cursor?

All three of these give you a `Cursor` when you are done. In Android, a `Cursor` represents the entire result set of the query — all the rows and all the columns that the query returned. In this respect, it is reminiscent of a "client-side cursor" from toolkits like ODBC, JDBC, etc.

(if the `Cursor` result set is over 1MB, it actually only holds a "window" on the data, and the story gets really really complicated...)

As such, a `Cursor` can be quite the memory hog. Please `close()` the `Cursor` when you are done with it, to free up the heap space it consumes and make that memory available to the rest of your application.

Using the Cursor Manually

With the `Cursor`, you can:

1. Find out how many rows are in the result set via `getCount()`
2. Iterate over the rows via `moveToFirst()`, `moveToNext()`, and `isAfterLast()`
3. Find out the names of the columns via `getColumnNames()`, convert those into column numbers via `getColumnIndex()`, and get values for the current row for a given column via methods like `getString()`, `getInt()`, etc.

For example, here we iterate over a fictitious `widgets` table's rows:

```
Cursor result=
  db.rawQuery("SELECT _id, name, inventory FROM widgets", null);

while (result.moveToNext()) {
  int id=result.getInt(0);
  String name=result.getString(1);
  int inventory=result.getInt(2);

  // do something useful with these
}

result.close();
```

Introducing CursorAdapter

Another way to use a `Cursor` is to wrap it in a `CursorAdapter`. Just as `ArrayAdapter` adapts arrays, `CursorAdapter` adapts `Cursor` objects, making their data available to an `AdapterView` like a `ListView`.

The easiest way to set one of these up is to use `SimpleCursorAdapter`, which extends `CursorAdapter` and provides some boilerplate logic for taking values out of columns and putting them into row `View` objects for a `ListView` (or other `AdapterView`). The sample app does just that:

```
    SimpleCursorAdapter adapter=
        new SimpleCursorAdapter(getActivity(), R.layout.row,
            current, new String[] {
            DatabaseHelper.TITLE,
            DatabaseHelper.VALUE },
            new int[] { R.id.title, R.id.value },
            0);

    setListAdapter(adapter);
```

(from Database/ConstantsROWID/app/src/main/java/com/commonsware/android/constants/ConstantsFragment.java)

Here, we are telling `SimpleCursorAdapter` to take rows out of a `Cursor` named `current`, turning each into an inflated `R.layout.row` `ViewGroup`, in this case, a `RelativeLayout` holding a pair of `TextView` widgets:

```
<?xml version="1.0" encoding="utf-8"?>
<RelativeLayout xmlns:android="http://schemas.android.com/apk/res/android"
  android:layout_width="match_parent"
  android:layout_height="wrap_content">

  <TextView
    android:id="@+id/title"
    android:layout_width="wrap_content"
    android:layout_height="wrap_content"
    android:layout_alignParentLeft="true"
    android:textSize="20sp"
    android:textStyle="bold"/>

  <TextView
    android:id="@+id/value"
    android:layout_width="wrap_content"
    android:layout_height="wrap_content"
    android:layout_alignParentRight="true"
    android:textSize="20sp"
    android:textStyle="bold"/>

</RelativeLayout>
```

(from Database/ConstantsROWID/app/src/main/res/layout/row.xml)

For each row in the `Cursor`, the columns named `title` and `value` (represented by `TITLE` and `VALUE` constants on `DatabaseHelper`) are to be poured into their respective `TextView` widgets (`R.id.title` and `R.id.value`).

Note, though, that if you are going to use `CursorAdapter` or its subclasses (like `SimpleCursorAdapter`), your result set of your query *must* contain an integer column named `_id` that is unique for the result set. This "id" value is then supplied to methods like `onListItemClick()`, to identify what item the user clicked upon in the `AdapterView`. Note that this requirement is on the result set in the `Cursor`, so if you have a suitable column in a table that is not named `_id`, you can rename it in your query (e.g., `SELECT key AS _id, ...`).

However, if you want, you can use the built-in `ROWID`

Quoting the SQLite documentation:

> In SQLite, every row of every table has a 64-bit signed integer ROWID. The ROWID for each row is unique among all rows in the same table. You can access the ROWID of an SQLite table using one the special column names ROWID, _ROWID_, or OID... If a table contains a column of type INTEGER PRIMARY KEY, then that column becomes an alias for the ROWID. You can then access the ROWID using any of four different names, the original three names described above or the name given to the INTEGER PRIMARY KEY column. All these names are aliases for one another and work equally well in any context.

With that in mind, if you want to query SQLite and use the results in a `CursorAdapter`, but you do not have your own `INTEGER PRIMARY KEY` column, you can just include `ROWID` in your query, renaming it to `_id` to satisfy `CursorAdapter`.

That is why we have the `ROWID AS _id` in the `doQuery()` method: to satisfy this `_id` requirement of `CursorAdapter`.

Also note that you cannot `close()` the `Cursor` used by a `CursorAdapter` until you no longer need the `CursorAdapter`. That is why we do not close the `Cursor` until `onDestroy()` of the fragment:

```
@Override
public void onDestroy() {
  if (task!=null) {
    task.cancel(false);
  }

  ((CursorAdapter)getListAdapter()).getCursor().close();
  db.close();

  super.onDestroy();
}
```

(from Database/ConstantsROWID/app/src/main/java/com/commonsware/android/constants/ConstantsFragment.java)

We retrieve the `Cursor` from the `CursorAdapter`, which we get by calling `getListAdapter()` on the fragment.

Getting Data Out, Asynchronously

Ideally, queries are done on a background thread, as they may take some time.

One approach for doing that is to use an `AsyncTask`. In the sample application, `ConstantsFragment` kicks off a `LoadCursorTask` in `onViewCreated()` (shown above). `LoadCursorTask` extends the `BaseTask` class mentioned previously, where the `doQuery()` method resides. `LoadCursorTask` is responsible for doing the query (via the `doQuery()` method shown above) and putting the results in the `ListView` inside the fragment (using the `SimpleCursorAdapter` shown above):

```
abstract private class BaseTask<T> extends AsyncTask<T, Void, Cursor> {
  @Override
  public void onPostExecute(Cursor result) {
    ((CursorAdapter)getListAdapter()).changeCursor(result);
    current=result;
    task=null;
  }

  Cursor doQuery() {
    Cursor result=
        db
            .getReadableDatabase()
            .query(DatabaseHelper.TABLE,
                new String[] {"ROWID AS _id",
                              DatabaseHelper.TITLE,
                              DatabaseHelper.VALUE},
                null, null, null, null, DatabaseHelper.TITLE);

    result.getCount();

    return(result);
  }
}

private class LoadCursorTask extends BaseTask<Void> {
  @Override
  protected Cursor doInBackground(Void... params) {
    return(doQuery());
  }
}
```

(from Database/ConstantsROWID/app/src/main/java/com/commonsware/android/constants/ConstantsFragment.java)

We execute the actual query in `doInBackground()` and call `getCount()` on the `Cursor`, to force it to actually perform the query — `query()` returns the `Cursor`, but the query is not actually executed until we do something that needs the result set. This also holds true for `rawQuery()`, which is why we need to make sure to "touch" the `Cursor` while we are on the background thread.

onPostExecute() then uses changeCursor() to replace the Cursor in the SimpleCursorAdapter with the results. Since our SimpleCursorAdapter was created with a null Cursor, changeCursor() just slides in the new Cursor, telling the ListView that the data changed. This causes our ListView to be populated.

This way, the UI will not be frozen while the query is being executed, yet we only update the UI from the main application thread.

Note that the first time we try using the SQLiteOpenHelper is in our background thread. SQLiteOpenHelper will not try creating our database (e.g., for a new app install) until we call getReadableDatabase() or getWritableDatabase(). Hence, onCreate() (or, later, onUpgrade()) of our SQLiteOpenHelper will wind up being called on the background thread as well, meaning that the time spent creating (or upgrading) the database also does not freeze the UI.

Also note that in onDestroy(), as shown previously, we call cancel() on the AsyncTask if it is not null. If the task is still running, calling cancel() will prevent onPostExecute() from being invoked, and we will not have to worry about updating our UI after the fragment has been destroyed.

The Rest of the CRUD

To get data out of a database, it is generally useful to put data into it in the first place. The sample app starts by loading in data when the database is created (in onCreate() of DatabaseHelper), plus has an action bar item to allow the user to add other constants as needed.

In this section, we will examine in further detail how we manipulate the database, for both the write aspects of CRUD (create-read-update-delete) and for data definition language (DDL) operations (creating tables, creating indexes, etc.).

The Primary Option: execSQL()

For creating your tables and indexes, you will need to call execSQL() on your SQLiteDatabase, providing the DDL statement you wish to apply against the database. Barring a database error, this method returns nothing.

So, for example, you can call execSQL() to create the constants table, as shown in the DatabaseHelper onCreate() method:

```
    db.execSQL("CREATE TABLE constants (title TEXT, value REAL);");
```

(from Database/ConstantsROWID/app/src/main/java/com/commonsware/android/constants/DatabaseHelper.java)

This will create a table, named `constants`, with two data columns: `title` (text) and `value` (a float, or "real" in SQLite terms).

Most likely, you will create tables and indexes when you first create the database, or possibly when the database needs upgrading to accommodate a new release of your application. If you do not change your table schemas, you might never drop your tables or indexes, but if you do, just use `execSQL()` to invoke `DROP INDEX` and `DROP TABLE` statements as needed.

Alternative Options

For inserts, updates, and deletes of data, you have two choices. You can always use `execSQL()`, just like you did for creating the tables. The `execSQL()` method works for any SQL that does not return results, so it can handle `INSERT`, `UPDATE`, `DELETE`, etc. just fine.

Your alternative is to use the `insert()`, `update()`, and `delete()` methods on the `SQLiteDatabase` object, which eliminate much of the SQL syntax required to do basic operations.

For example, here we `insert()` a new row into our `constants` table, again from `onCreate()` of `DatabaseHelper`:

```
    ContentValues cv=new ContentValues();

    cv.put(TITLE, "Gravity, Death Star I");
    cv.put(VALUE, SensorManager.GRAVITY_DEATH_STAR_I);
    db.insert(TABLE, TITLE, cv);
```

(from Database/ConstantsROWID/app/src/main/java/com/commonsware/android/constants/DatabaseHelper.java)

These methods make use of `ContentValues` objects, which implement a `Map`-esque interface, albeit one that has additional methods for working with SQLite types. For example, in addition to `get()` to retrieve a value by its key, you have `getAsInteger()`, `getAsString()`, and so forth.

The `insert()` method takes the name of the table, the name of one column as the "null column hack", and a `ContentValues` with the initial values you want put into this row. The "null column hack" is for the case where the `ContentValues` instance is

empty — the column named as the "null column hack" will be explicitly assigned the value `NULL` in the SQL `INSERT` statement generated by `insert()`. This is required due to a quirk in SQLite's support for the SQL `INSERT` statement.

The `update()` method takes the name of the table, a `ContentValues` representing the columns and replacement values to use, an optional `WHERE` clause, and an optional list of parameters to fill into the `WHERE` clause, to replace any embedded question marks (`?`). Since `update()` only replaces columns with fixed values, versus ones computed based on other information, you may need to use `execSQL()` to accomplish some ends. The `WHERE` clause and parameter list works akin to the positional SQL parameters you may be used to from other SQL APIs.

The `delete()` method works akin to `update()`, taking the name of the table, the optional `WHERE` clause, and the corresponding parameters to fill into the `WHERE` clause.

Asynchronous CRUD and UI Updates

Just as querying a database should be done on a background thread, so should modifying a database. This is why it is important to make the first time you request a `SQLiteDatabase` from a `SQLiteOpenHelper` be on a background thread, in case `onCreate()` or `onUpgrade()` are needed.

The same thing holds true if you need to update the database during normal operation of your app. For example, the sample application has an "add" action bar item in the upper-right corner of the screen:

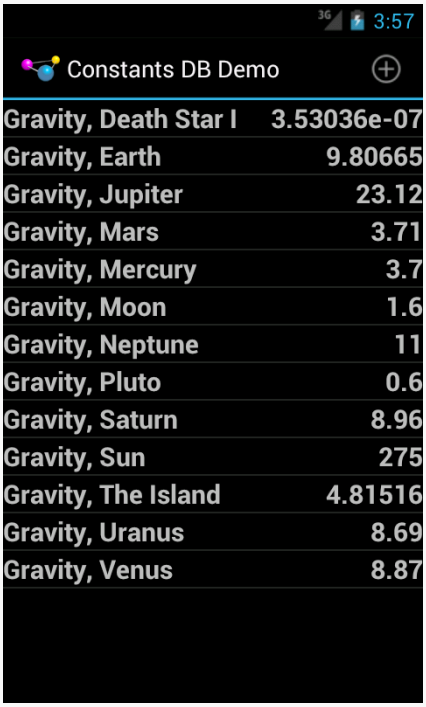

Figure 294: The ConstantsBrowser Sample

Clicking on that brings up a dialog — a technique we will discuss later in this book:

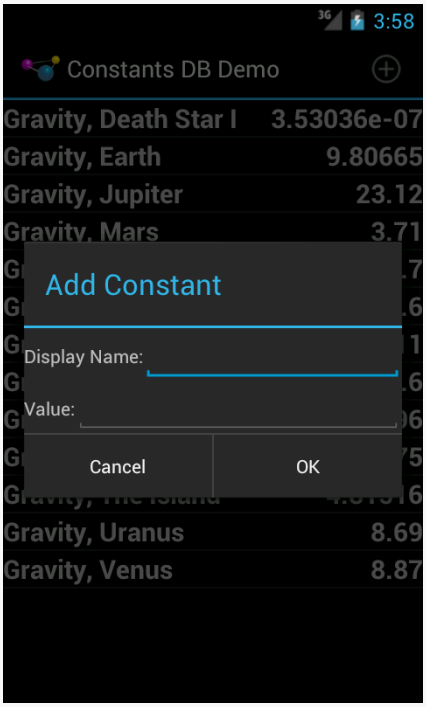

Figure 295: The ConstantsBrowser Sample, Add Constant Dialog

If the user fills in a constant and clicks the "OK" button, we need to insert a new record in the database. That is handled via an `InsertTask`:

```
private class InsertTask extends BaseTask<ContentValues> {
  @Override
  protected Cursor doInBackground(ContentValues... values) {
    db.getWritableDatabase().insert(DatabaseHelper.TABLE,
                                    DatabaseHelper.TITLE, values[0]);

    return(doQuery());
  }
}
```

(from Database/ConstantsROWID/app/src/main/java/com/commonsware/android/constants/ConstantsFragment.java)

The `InsertTask` is supplied a `ContentValues` object with our `title` and `value`, just as we used in `onCreate()` of `DatabaseHelper`. In `doInBackground()`, we get a writable database from `DatabaseHelper` and perform the `insert()` call, so the database I/O does not tie up the main application thread.

However, in `doInBackground()`, we *also* call `doQuery()` again. This retrieves a fresh `Cursor` with the new roster of constants... including the one we just inserted. As with

LoadCursorTask, we execute doQuery() in doInBackground() to keep the database I/O off the main application thread. This triggers the same onPostExecute() as before, inherited from BaseTask, which uses changeCursor() to replace any existing results with the new results.

Setting Transaction Bounds

By default, each SQL statement executes in its own transaction — this is fairly typical behavior for a SQL database, and SQLite is no exception.

There are two reasons why you might want to have your own transaction bounds, larger than a single statement:

1. The classic "we have a series of operations that need to succeed or fail as a whole" rationale, for maintaining data integrity
2. Performance, as each database transaction involves disk I/O, and one large transaction will be much faster than lots of little transactions

The basic recipe for your own transactions is:

```
try {
  db.beginTransaction();

  // several SQL statements in here

  db.setTransactionSuccessful();
}
finally {
  db.endTransaction();
}
```

beginTransaction() marks the fact that you want a transaction. setTransactionSuccessful() indicates that you want the transaction to commit. However, the actual COMMIT or ROLLBACK does not occur until endTransaction(). In the normal case, setTransactionSuccessful() does get called, and endTransaction() performs a COMMIT. If, however, one of your SQL statements fails (e.g., violates a foreign key constraint), the setTransactionSuccessful() call is skipped, so endTransaction() will do a ROLLBACK.

You might wonder why we did not bother with a transaction in onCreate() method of DatabaseHelper, given the latter reason. That is because onCreate() is called

within a transaction set up by `SQLiteOpenHelper` itself, so you do not need your own.

Hey, What About Hibernate?

Those of you with significant Java backgrounds outside of Android are probably pounding your head against your desk right about now. Outside of a few conveniences like `SQLiteOpenHelper` and `CursorAdapter`, Android's approach to database I/O feels a bit like classic JDBC. Java developers, having experienced the pain of raw JDBC, created various wrappers around it, the most prominent of which is an ORM (object-relational mapper) called Hibernate.

Alas, Hibernate is designed for servers, not mobile devices. It is a little bit heavyweight, and it is designed for use with JDBC, not Android's SQLite classes.

Android did not include any sort of ORM in the beginning for two main reasons:

1. To keep the firmware size as small as possible, as smaller firmware can lead to less-expensive devices
2. To eliminate the ORM overhead (e.g., reflection), which would have been too much for early Android versions on early Android devices

The Android ecosystem has come up with alternatives, such as ORMLite and greenDAO. So, if you are used to using an ORM, you may want to investigate these sorts of solutions — they just are not built into Android itself.

But, What About Room?

In 2017, Google introduced the Architecture Components: a set of libraries designed to offer higher-level abstractions around core architecture concerns. One piece of the Architecture Components is Room, which is Google's take on object-relational mapping code.

Room is covered in the companion volume, "Android's Architecture Components".

Visit the Trails!

If you are interested in exposing your database contents to a third-party application, you may wish to read up on `ContentProvider`.

The trails also have chapters on encrypted databases using SQLCipher and shipping pre-packaged databases with your app.

Tutorial #14 - Saving Notes

It would be nice if the user could add some personal notes to the chapter that she is reading, whether that serves as commentary, points to be researched, complaints about the author's hair (or lack thereof), or whatever.

So, in this chapter, we will add a new fragment and new activity to allow the user to add notes per chapter, via a large `EditText` widget. Those notes will be stored in a SQLite database.

This is a continuation of the work we did in the previous tutorial.

You can find the results of the previous tutorial and the results of this tutorial in the book's GitHub repository.

Step #1: Adding a DatabaseHelper

The first step for working with SQLite is to add an implementation of `SQLiteOpenHelper`, which we will do here, named `DatabaseHelper`.

Right-click over the `com.commonsware.empublite` package in your `java/` directory and choose New > Java Class from the context menu. Fill in `DatabaseHelper` as the name and `android.database.sqlite.SQLiteOpenHelper` as the superclass. Then, click OK to create the empty class.

Then, replace the contents of that class with the following:

```
package com.commonsware.empublite;

import android.content.Context;
import android.database.sqlite.SQLiteDatabase;
```

```
import android.database.sqlite.SQLiteOpenHelper;

public class DatabaseHelper extends SQLiteOpenHelper {
  private static final String DATABASE_NAME="empublite.db";
  private static final int SCHEMA_VERSION=1;
  private static DatabaseHelper singleton=null;

  synchronized static DatabaseHelper getInstance(Context ctxt) {
    if (singleton == null) {
      singleton=new DatabaseHelper(ctxt.getApplicationContext());
    }

    return(singleton);
  }

  private DatabaseHelper(Context ctxt) {
    super(ctxt, DATABASE_NAME, null, SCHEMA_VERSION);
  }

  @Override
  public void onCreate(SQLiteDatabase db) {
    db.execSQL("CREATE TABLE notes (position INTEGER PRIMARY KEY, prose TEXT);");
  }

  @Override
  public void onUpgrade(SQLiteDatabase db, int oldVersion,
                        int newVersion) {
    throw new RuntimeException("This should not be called");
  }
}
```

Step #2: Examining DatabaseHelper

Our initial version of `DatabaseHelper` has a few things:

- It has the constructor, supplying to the superclass the name of the database file (`DATABASE_NAME`) and the revision number of our schema (`SCHEMA_VERSION`). Note that the constructor is private, as we are using the singleton pattern, so only `DatabaseHelper` should be able to create `DatabaseHelper` instances.
- It has the `onCreate()` method, invoked the first time we run the app on a device or emulator, to let us populate the database. Here, we use `execSQL()` to define a `notes` table with a `position` column (indicating our chapter) and a `prose` column (what the user types in as the note).

- It has the `onUpgrade()` method, needed because `SQLiteOpenHelper` is abstract, so our app will not compile without an implementation. Until we revise our schema, though, this method should never be called, so we raise a `RuntimeException` in the off chance that it *is* called unexpectedly.
- It has a static `DatabaseHelper` singleton instance and a `getInstance()` method to lazy-initialize it.

As noted in the chapter on databases, it is important to ensure that all threads are accessing the same `SQLiteDatabase` object, for thread safety. That usually means you hold onto a single `SQLiteOpenHelper` object. And, in our case, we might want to get at this database from more than one activity. Hence, we go with the singleton approach, so everyone works with the same `DatabaseHelper` instance.

Step #3: Creating a NoteFragment

Having a database is nice and all, but we need to work on the UI to allow users to enter notes. To do that, we will start with a `NoteFragment`.

Right-click over the `com.commonsware.empublite` package in your `java/` directory and choose New > Java Class from the context menu. Fill in `NoteFragment` as the name and `android.app.Fragment` as the superclass. Then, click OK to create the empty class.

Next, replace the contents of that class with the following:

```
package com.commonsware.empublite;

import android.app.Fragment;
import android.os.Bundle;
import android.view.LayoutInflater;
import android.view.View;
import android.view.ViewGroup;
import android.widget.EditText;

public class NoteFragment extends Fragment {
  private static final String KEY_POSITION="position";
  private EditText editor=null;

  static NoteFragment newInstance(int position) {
    NoteFragment frag=new NoteFragment();
    Bundle args=new Bundle();

    args.putInt(KEY_POSITION, position);
```

```
    frag.setArguments(args);

    return(frag);
  }

  @Override
  public View onCreateView(LayoutInflater inflater,
                           ViewGroup container,
                           Bundle savedInstanceState) {
    View result=inflater.inflate(R.layout.editor, container, false);

    editor=(EditText)result.findViewById(R.id.editor);

    return(result);
  }

  private int getPosition() {
    return(getArguments().getInt(KEY_POSITION, -1));
  }
}
```

Note that this fragment uses the `res/layout/editor.xml` resource that we created back in Tutorial #5.

Step #4: Examining NoteFragment

Our `NoteFragment` is fairly straightforward and is reminiscent of the `SimpleContentFragment` we created in Tutorial #11.

`NoteFragment` has a `newInstance()` static factory method. This method creates an instance of `NoteFragment`, takes a passed-in `int` (identifying the chapter for which we are creating a note), puts it in a `Bundle` identified as `KEY_POSITION`, hands the `Bundle` to the fragment as its arguments, and returns the newly-created `NoteFragment`.

In `onCreateView()`, we inflate the `R.layout.editor` resource that we defined and get our hands on our `EditText` widget for later use.

Step #5: Creating the NoteActivity

Having a fragment without displaying it is fairly pointless, so we need something to load a `NoteFragment`. Particularly for phones, the simplest answer is to create a

NoteActivity for that, paralleling the relationship between SimpleContentFragment and SimpleContentActivity.

Right-click over the com.commonsware.empublite package in your java/ directory and choose New > Activity > Empty Activity from the context menu. Fill in NoteActivity as the name, uncheck all the checkboxes, and click OK to create the empty class.

In the NoteActivity class that is created, replace the current implementation with the following:

```
package com.commonsware.empublite;

import android.app.Activity;
import android.app.Fragment;
import android.os.Bundle;

public class NoteActivity extends Activity {
  public static final String EXTRA_POSITION="position";

  @Override
  public void onCreate(Bundle savedInstanceState) {
    super.onCreate(savedInstanceState);

    if (getFragmentManager().findFragmentById(android.R.id.content) == null) {
      int position=getIntent().getIntExtra(EXTRA_POSITION, -1);

      if (position >= 0) {
        Fragment f=NoteFragment.newInstance(position);

        getFragmentManager().beginTransaction()
                            .add(android.R.id.content, f).commit();
      }
    }
  }
}
```

Step #6: Examining NoteActivity

As you can see, this is a fairly trivial activity. In onCreate(), if we are being created anew, we execute a FragmentTransaction to add a NoteFragment to our activity, pouring it into the full screen (android.R.id.content). Here, android.R.id.content identifies the container into which the results of

`setContentView()` would go — it is a container supplied by Activity itself and serves as the top-most container for our content.

However, we expect that we will be passed an `Intent` extra with the position (`EXTRA_POSITION`), which we pass along to the `NoteFragment` factory method.

Step #7: Add Notes to the Action Bar

Of course, none of this is useful if we do not give the user a way to get to the `NoteActivity`. Specifically, we can add a `notes` entry to our `res/menu/options.xml` resource, to have a new toolbar button appear on our main activity's action bar.

Right-click over the `res/` directory and choose New > Vector Asset from the context menu. Click the Icon button and search for the "Create" icon:

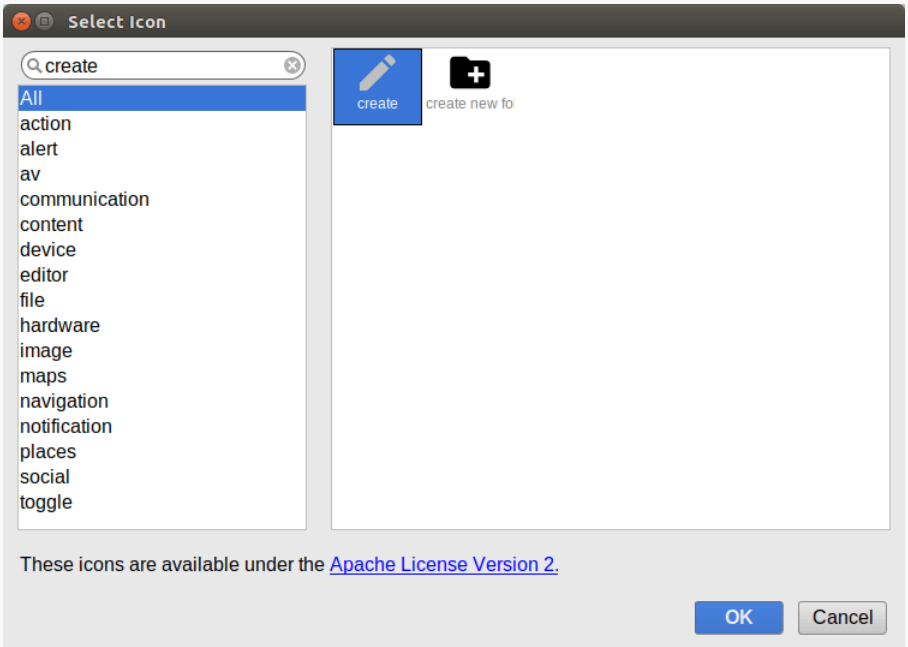

Figure 296: Asset Studio Icon Picker, with Create Icon Selected

Click OK to close the icon picker. Then click Next and Finish to save this drawable resource.

Unfortunately, this icon will render in black, when we need it to render in white given our theme. Right click over `res/drawable/ic_create_black_24dp.xml`, choose Refactor > Rename from the context menu, and change the name to

`ic_create_white_24dp.xml`. Then, open `res/drawable/ic_create_white_24dp.xml` and change the `android:fillColor` in the `<path>` element to be `#FFFFFFFF` instead of `#FF000000`:

```
<vector xmlns:android="http://schemas.android.com/apk/res/android"
        android:width="24dp"
        android:height="24dp"
        android:viewportWidth="24.0"
        android:viewportHeight="24.0">
    <path
        android:fillColor="#FFFFFFFF"
        android:pathData="M3,17.25V21h3.75L17.81,9.94l-3.75,-3.75L3,17.25zM20.71,7.04c0.39,-0.39
0.39,-1.02 0,-1.41l-2.34,-2.34c-0.39,-0.39 -1.02,-0.39 -1.41,0l-1.83,1.83 3.75,3.75 1.83,-1.83z"/>
</vector>
```

(from EmPubLite-AndroidStudio/T14-Database/EmPubLite/app/src/main/res/drawable/ic_create_white_24dp.xml)

Next, add a new string resource, named `notes`, with a value like `Notes`.

Then, modify `res/menu/options.xml` to look like:

```
<?xml version="1.0" encoding="utf-8"?>
<menu xmlns:android="http://schemas.android.com/apk/res/android">

  <item
    android:id="@+id/notes"
    android:icon="@drawable/ic_create_white_24dp"
    android:showAsAction="ifRoom|withText"
    android:title="@string/notes">
  </item>
  <item
    android:id="@+id/settings"
    android:icon="@drawable/ic_settings_black_24dp"
    android:showAsAction="never"
    android:title="@string/settings">
  </item>
  <item
    android:id="@+id/help"
    android:icon="@drawable/ic_help_outline_black_24dp"
    android:title="@string/help">
  </item>
  <item
    android:id="@+id/about"
    android:icon="@drawable/ic_info_outline_black_24dp"
    android:title="@string/about">
  </item>

</menu>
```

(from EmPubLite-AndroidStudio/T14-Database/EmPubLite/app/src/main/res/menu/options.xml)

Finally, in `EmPubLiteActivity`, add the following `case` to the `switch` statement in `onOptionsItemSelected()`:

```
      case R.id.notes:
        startActivity(new Intent(this, NoteActivity.class)
          .putExtra(NoteActivity.EXTRA_POSITION,
            pager.getCurrentItem()));

        return(true);
```

(from EmPubLite-AndroidStudio/T14-Database/EmPubLite/app/src/main/java/com/commonsware/empublite/EmPubLiteActivity.java)

Here, we get the currently-viewed position from the `ViewPager` and pass that as the `EXTRA_POSITION` extra to `NoteActivity`.

Step #8: Defining a NoteLoadedEvent

We will want to load notes from the database on a background thread. Hence, we can apply the same basic approach as we used with `ModelFragment`, posting an event on the greenrobot EventBus when the load is completed, to deliver the results to the `NoteFragment`. This step will create a `NoteLoadedEvent` to handle this case.

Right-click over the `com.commonsware.empublite` package in your `java/` directory and choose New > Java Class from the context menu. Fill in `NoteLoadedEvent` as the name and click OK to create the empty class.

Then, replace the contents of that class with the following:

```
package com.commonsware.empublite;

class NoteLoadedEvent {
  int position;
  String prose;

  NoteLoadedEvent(int position, String prose) {
    this.position=position;
    this.prose=prose;
  }

  int getPosition() {
    return(position);
  }
```

```
  String getProse() {
    return(prose);
  }
}
```

(from EmPubLite-AndroidStudio/T14-Database/EmPubLite/app/src/main/java/com/commonsware/empublite/NoteLoadedEvent.java)

If you prefer, you can view this file's contents in your Web browser via this GitHub link.

Step #9: Loading a Note from the Database

Next, we need to add code somewhere that will actually query the database (on a background thread) to load the note for a given `ViewPager` position. One common pattern is to put this sort of database-access logic on your `SQLiteOpenHelper` subclass, so all of your database-specific code resides in one place. That is the approach we will take here, adding a `loadNote()` method that will fork a thread, query the database, and post a `NoteLoadedEvent` as a result.

Edit your `DatabaseHelper` to add its own `LoadThread` inner class, reminiscent of the one from `ModelFragment`:

```
private class LoadThread extends Thread {
  private int position=-1;

  LoadThread(int position) {
    super();
    this.position=position;
  }

  @Override
  public void run() {
    Process.setThreadPriority(Process.THREAD_PRIORITY_BACKGROUND);

    String[] args={String.valueOf(position)};
    Cursor c=
      getReadableDatabase().rawQuery("SELECT prose FROM notes WHERE position = ? ", args);

    if (c.getCount() > 0) {
      c.moveToFirst();

      EventBus.getDefault().post(new NoteLoadedEvent(position,
        c.getString(0)));
    }

    c.close();
  }
}
```

(from EmPubLite-AndroidStudio/T14-Database/EmPubLite/app/src/main/java/com/commonsware/empublite/DatabaseHelper.java)

Here, we use `rawQuery()` to retrieve the note based upon a supplied position. If there is no such note, our `Cursor` will have no rows, and we are done. If, however, we did get results back on the query, we then post a `NoteLoadedEvent` with the `position` and the `prose` (the text from the database).

You will need to add an import manually to `android.os.Process`, to be able to resolve the `setThreadPriority()` method and its parameter.

Also, add a `loadNote()` method to `DatabaseHelper` that forks this `LoadThread`:

```
void loadNote(int position) {
  new LoadThread(position).start();
}
```

(from EmPubLite-AndroidStudio/T14-Database/EmPubLite/app/src/main/java/com/commonsware/empublite/DatabaseHelper.java)

Step #10: Loading the Note Into the Fragment

Now that we can query the database and get back a note (if any), we can tie that into the `NoteFragment` to load the note for the fragment's `position` when the fragment is opened. We will not only need to call `loadNote()` on the `DatabaseHelper`, but also be able to respond to the `NoteLoadedEvent` when it arrives.

Add the following `onStart()` method to `NoteFragment`:

```
@Override
public void onStart() {
  super.onStart();

  EventBus.getDefault().register(this);

  if (TextUtils.isEmpty(editor.getText())) {
    DatabaseHelper db=DatabaseHelper.getInstance(getActivity());
    db.loadNote(getPosition());
  }
}
```

(from EmPubLite-AndroidStudio/T14-Database/EmPubLite/app/src/main/java/com/commonsware/empublite/NoteFragment.java)

Here, we register for the `EventBus`. Then, if we do not have any text in the `EditText` widget, we call `loadNote()` on our singleton instance of the `DatabaseHelper`, passing in the `position` that our fragment is managing. The reason for checking to see if the `EditText` is empty is to handle configuration changes. This fragment is not a retained fragment, and so it will be destroyed and re-created. The default

`onSaveInstanceState()` logic of `EditText` will retain our note, though, so we do not want to re-load it from the database. This approach is not optimal, in that we will wind up calling `loadNote()` in cases where we could know that there is no note. That optimization is complex enough to not make it worthwhile for a set of book tutorials, though it is something you might wish to explore in a commercial-grade application.

Next, add the corresponding `onStop()` to `NoteFragment`, to unregister from the `EventBus`:

```
@Override
public void onStop() {
  EventBus.getDefault().unregister(this);

  super.onStop();
}
```

Finally, add an `onNoteLoaded(NoteLoadedEvent)` method to `NoteFragment`, so we receive the `NoteLoadedEvent` on the main application thread:

```
@SuppressWarnings("unused")
@Subscribe(threadMode =ThreadMode.MAIN)
public void onNoteLoaded(NoteLoadedEvent event) {
  if (event.getPosition() == getPosition()) {
    editor.setText(event.getProse());
  }
}
```

(from EmPubLite-AndroidStudio/T14-Database/EmPubLite/app/src/main/java/com/commonsware/empublite/NoteFragment.java)

Here, we confirm that the event is for our fragment's position, as it is conceivable that this event is for some other note, though that is rather unlikely given how the user would view notes. That being said, if the note is for our position, we populate the `EditText` with the note prose.

Step #11: Updating the Database

Of course, loading notes from a database is all fine and well... except that we do not have any notes *in* the database. We really should fix that.

Add an `UpdateThread` inner class to `DatabaseHelper`:

```
private class UpdateThread extends Thread {
  private int position=-1;
```

```
  private String prose=null;

  UpdateThread(int position, String prose) {
    super();
    this.position=position;
    this.prose=prose;
  }

  @Override
  public void run() {
    Process.setThreadPriority(Process.THREAD_PRIORITY_BACKGROUND);

    String[] args={String.valueOf(position), prose};
    getWritableDatabase().execSQL("INSERT OR REPLACE INTO notes (position, prose) VALUES (?, ?)",
      args);
  }
}
```

(from EmPubLite-AndroidStudio/T14-Database/EmPubLite/app/src/main/java/com/commonsware/empublite/DatabaseHelper.java)

Here, we use `execSQL()` to execute an `INSERT OR REPLACE` SQL statement. As the name suggests, this will insert a new row if there is no match on our primary key (`position`). Otherwise, it will update the other columns if there is a match.

Note that we do not post an event here. We could, if there was something in the app that needed to know when a note was updated.

Also, add an `updateNote()` method to `DatabaseHelper` that forks this `UpdateThread`:

```
void updateNote(int position, String prose) {
  new UpdateThread(position, prose).start();
}
```

(from EmPubLite-AndroidStudio/T14-Database/EmPubLite/app/src/main/java/com/commonsware/empublite/DatabaseHelper.java)

Step #12: Saving the Note

Somewhere, we need to call `updateNote()`. A classic "desktop" approach would be to have a "save" action bar item in the `NoteFragment`, which the user would need to click upon to save the note. However, this does not deal with the interrupt-driven nature of phones all that well. For example, the user might start typing in a note, then wind up taking a phone call. If our process is terminated, depending upon how the user tries getting back into our app, we might not have the note from our saved instance state.

A better approach, in many cases, is to save data in `onStop()`, when the activity moves into the background. If there is a chance that the user might not want the

partially-entered information, you could save it in a "side" area, such as a temporary file, and deal with it when the user returns to your app. Or, you could just update the real data store... which is what we will do here.

Edit the `onStop()` method in `NoteFragment` to look like the following:

```
@Override
public void onStop() {
  DatabaseHelper.getInstance(getActivity())
    .updateNote(getPosition(),
      editor.getText().toString());

  EventBus.getDefault().unregister(this);

  super.onStop();
}
```

(from EmPubLite-AndroidStudio/T14-Database/EmPubLite/app/src/main/java/com/commonsware/empublite/NoteFragment.java)

Here, we update the note. This is a bit inefficient, as we update the database even if the user did not change the text of the note, or even if the note is empty. That represents another optimization that a production-grade app might wish to pursue but is skipped here in the interests of simplicity.

If you build and run the app on a device or emulator, you will see the new "notes" toolbar button in the action bar:

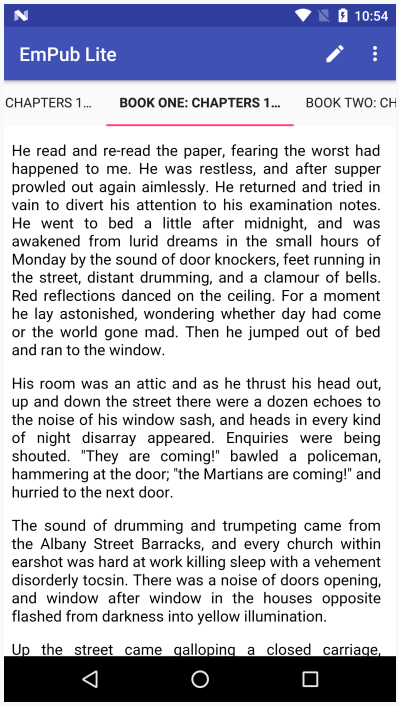

Figure 297: The New Action Bar Item

Tapping that will bring up the notes for whatever `ViewPager` position that you are on. Entering in some notes and pressing BACK to exit the activity will save those notes, which you will see again if you tap the action bar toolbar button again. If you change the notes, pressing BACK will save the changed notes in the database, to be viewed again later when you go back into the notes for that `ViewPager` position.

Step #13: Adding a Delete Action Bar Item

The only problem with this solution is that the notes never leave. While the user could manually delete everything in the `EditText`, it would be nice to make that perhaps a bit simpler. In this step, we will add an action bar item that will clear the `EditText` for the user.

Right-click over the `res/` directory and choose New > Vector Asset from the context menu. Click the Icon button and search for the “delete” icon:

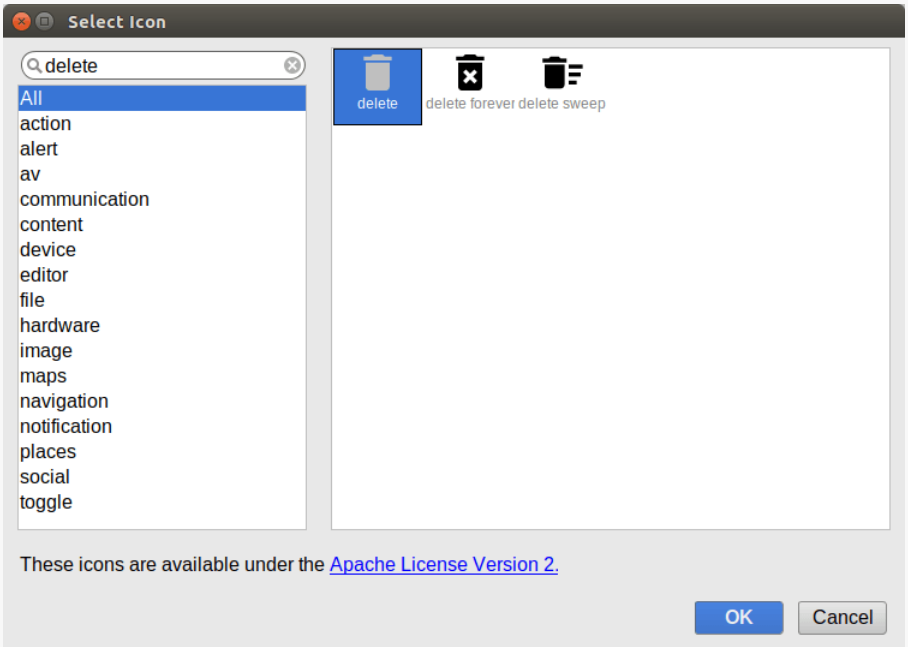

Figure 298: Asset Studio Icon Picker, with Delete Icon Selected

Click OK to close the icon picker. Change the name of the resource to `ic_delete_white_24dp`. Then click Next and Finish to save this drawable resource. Then, open `res/drawable/ic_delete_white_24dp.xml` and change the `android:fillColor` in the `<path>` element to be `#FFFFFFFF` instead of `#FF000000`:

```
<vector xmlns:android="http://schemas.android.com/apk/res/android"
        android:width="24dp"
        android:height="24dp"
        android:viewportWidth="24.0"
        android:viewportHeight="24.0">
    <path
        android:fillColor="#FFFFFFFF"
        android:pathData="M6,19c0,1.1 0.9,2 2,2h8c1.1,0 2,-0.9
2,-2V7H6v12zM19,4h-3.5l-1,-1h-5l-1,1H5v2h14V4z"/>
</vector>
```

(from EmPubLite-AndroidStudio/T14-Database/EmPubLite/app/src/main/res/drawable/ic_delete_white_24dp.xml)

Next, add a new string resource, named `delete`, with a value like `Delete`.

Then, create a new resource, `res/menu/notes.xml`, to configure the action bar for the activity hosting our `NoteFragment`:

```
<?xml version="1.0" encoding="utf-8"?>
<menu xmlns:android="http://schemas.android.com/apk/res/android">
  <item
```

```
    android:id="@+id/delete"
    android:icon="@drawable/ic_delete_white_24dp"
    android:showAsAction="ifRoom|withText"
    android:title="@string/delete">
  </item>
</menu>
```

(from EmPubLite-AndroidStudio/T14-Database/EmPubLite/app/src/main/res/menu/notes.xml)

This simply defines a single action bar item, with an ID of `delete`.

To do this, Android Studio users can right-click over the `res/menu/` directory and choose New > "Menu resource file" from the context menu. Fill in `notes.xml` in the "New Menu Resource File" dialog and click OK. Paste in the XML shown above into that file.

If you prefer, you can view this file's contents in your Web browser via this GitHub link.

To let Android know that our `NoteFragment` wishes to participate in the action bar, we need to call `setHasOptionsMenu(true)` at some point. Add an `onCreate()` method to `NoteFragment` to handle this when the fragment is created:

```
@Override
public void onCreate(Bundle savedInstanceState) {
  super.onCreate(savedInstanceState);

  setHasOptionsMenu(true);
}
```

(from EmPubLite-AndroidStudio/T14-Database/EmPubLite/app/src/main/java/com/commonsware/empublite/NoteFragment.java)

That will trigger a call to `onCreateOptionsMenu()`, which we will need to add to `NoteFragment`:

```
@Override
public void onCreateOptionsMenu(Menu menu, MenuInflater inflater) {
  inflater.inflate(R.menu.notes, menu);

  super.onCreateOptionsMenu(menu, inflater);
}
```

(from EmPubLite-AndroidStudio/T14-Database/EmPubLite/app/src/main/java/com/commonsware/empublite/NoteFragment.java)

This just inflates our new resource for use in the options menu.

If the user taps on that toolbar button, `onOptionsItemSelected()` will be called, so we will need to add that as well to `NoteFragment`:

```
@Override
public boolean onOptionsItemSelected(MenuItem item) {
  if (item.getItemId() == R.id.delete) {
    editor.setText(null);

    return(true);
  }

  return(super.onOptionsItemSelected(item));
}
```

Here, if the user tapped on our `delete` action bar item, we clear the `EditText` widget.

Step #14: Closing the NoteFragment When Deleted

However, tapping on that action bar item keeps the `NoteFragment` on the screen. It might be nice to automatically return to the book instead. However, the `NoteFragment` itself does not know how to do that, as something else (in this case, `NoteActivity`) put the `NoteFragment` on the screen. Hence, we need to pass the request to close the `NoteFragment` along to the proper party.

We could use another event object and our `EventBus`. In this case, we will demonstrate another approach: using the contract pattern to alert the hosting activity that the notes should be closed.

Define an *inner interface* in the `NoteFragment`, named `Contract`, as follows:

```
public interface Contract {
  void closeNotes();
}
```

(from EmPubLite-AndroidStudio/T14-Database/EmPubLite/app/src/main/java/com/commonsware/empublite/NoteFragment.java)

You might put those lines immediately after the `public class NoteFragment...` line, before the declaration of any of the data members or methods, for example.

Then, add a private `getContract()` method, that casts the hosting `Activity` to the `Contract` interface:

```
  private Contract getContract() {
    return((Contract)getActivity());
  }
```

(from EmPubLite-AndroidStudio/T14-Database/EmPubLite/app/src/main/java/com/commonsware/empublite/NoteFragment.java)

What we are doing here is enforcing that the activity that hosts our `NoteFragment` must implement the `NoteFragment.Contract` interface.

Then, add a call to `closeNotes()` on the `Contract` to our logic in `onOptionsItemSelected()`:

```
  @Override
  public boolean onOptionsItemSelected(MenuItem item) {
    if (item.getItemId() == R.id.delete) {
      editor.setText(null);
      getContract().closeNotes();

      return(true);
    }

    return(super.onOptionsItemSelected(item));
  }
```

(from EmPubLite-AndroidStudio/T14-Database/EmPubLite/app/src/main/java/com/commonsware/empublite/NoteFragment.java)

Now, when the user clicks on the `delete` action bar item, we clear the `EditText` and ask the hosting activity to get rid of us. Along the way, our `onPause()` will be called, causing us to clear the content of the `prose` column in our database row as well.

At this point, `NoteFragment` should resemble:

```
package com.commonsware.empublite;

import android.app.Fragment;
import android.os.Bundle;
import android.text.TextUtils;
import android.view.LayoutInflater;
import android.view.Menu;
import android.view.MenuInflater;
import android.view.MenuItem;
import android.view.View;
import android.view.ViewGroup;
import android.widget.EditText;
import org.greenrobot.eventbus.EventBus;
import org.greenrobot.eventbus.Subscribe;
```

```
import org.greenrobot.eventbus.ThreadMode;

public class NoteFragment extends Fragment {
  public interface Contract {
    void closeNotes();
  }

  private static final String KEY_POSITION="position";
  private EditText editor=null;

  static NoteFragment newInstance(int position) {
    NoteFragment frag=new NoteFragment();
    Bundle args=new Bundle();

    args.putInt(KEY_POSITION, position);
    frag.setArguments(args);

    return(frag);
  }

  @Override
  public void onCreate(Bundle savedInstanceState) {
    super.onCreate(savedInstanceState);

    setHasOptionsMenu(true);
  }

  @Override
  public View onCreateView(LayoutInflater inflater,
                           ViewGroup container,
                           Bundle savedInstanceState) {
    View result=inflater.inflate(R.layout.editor, container, false);

    editor=(EditText)result.findViewById(R.id.editor);

    return(result);
  }

  @Override
  public void onStart() {
    super.onStart();

    EventBus.getDefault().register(this);

    if (TextUtils.isEmpty(editor.getText())) {
      DatabaseHelper db=DatabaseHelper.getInstance(getActivity());
      db.loadNote(getPosition());
    }
```

```
  }

  @Override
  public void onStop() {
    DatabaseHelper.getInstance(getActivity())
      .updateNote(getPosition(),
        editor.getText().toString());

    EventBus.getDefault().unregister(this);

    super.onStop();
  }

  @Override
  public void onCreateOptionsMenu(Menu menu, MenuInflater inflater) {
    inflater.inflate(R.menu.notes, menu);

    super.onCreateOptionsMenu(menu, inflater);
  }

  @Override
  public boolean onOptionsItemSelected(MenuItem item) {
    if (item.getItemId() == R.id.delete) {
      editor.setText(null);
      getContract().closeNotes();

      return(true);
    }

    return(super.onOptionsItemSelected(item));
  }

  @SuppressWarnings("unused")
  @Subscribe(threadMode =ThreadMode.MAIN)
  public void onNoteLoaded(NoteLoadedEvent event) {
    if (event.getPosition() == getPosition()) {
      editor.setText(event.getProse());
    }
  }

  private int getPosition() {
    return(getArguments().getInt(KEY_POSITION, -1));
  }

  private Contract getContract() {
    return((Contract)getActivity());
  }
}
```

(from EmPubLite-AndroidStudio/T14-Database/EmPubLite/app/src/main/java/com/commonsware/empublite/NoteFragment.java)

`NoteActivity` now must implement `NoteFragment.Contract` and implement `closeNotes()`. Modify `NoteActivity` to look like:

```
package com.commonsware.empublite;

import android.app.Activity;
import android.app.Fragment;
import android.os.Bundle;

public class NoteActivity extends Activity
  implements NoteFragment.Contract {
  public static final String EXTRA_POSITION="position";

  @Override
  public void onCreate(Bundle savedInstanceState) {
    super.onCreate(savedInstanceState);

    if (getFragmentManager().findFragmentById(android.R.id.content) == null) {
      int position=getIntent().getIntExtra(EXTRA_POSITION, -1);

      if (position >= 0) {
        Fragment f=NoteFragment.newInstance(position);

        getFragmentManager().beginTransaction()
          .add(android.R.id.content, f).commit();
      }
    }
  }

  @Override
  public void closeNotes() {
    finish();
  }
}
```

(from EmPubLite-AndroidStudio/T14-Database/EmPubLite/app/src/main/java/com/commonsware/empublite/NoteActivity.java)

This adds the `implements` keyword and the `closeNotes()` implementation, which just finishes the `NoteActivity`, returning control to the `EmPubLiteActivity`.

If you run this in a device or emulator, and you go into the notes, you will see our delete toolbar button:

Figure 299: The New Action Bar Item

Tapping that toolbar button will clear the note and close the activity, returning you to the book.

In Our Next Episode…

… we will allow the user to share a chapter's notes with somebody else.

Internet Access

The expectation is that most, if not all, Android devices will have built-in Internet access. That could be WiFi, cellular data services (EDGE, 3G, etc.), or possibly something else entirely. Regardless, most people — or at least those with a data plan or WiFi access — will be able to get to the Internet from their Android phone.

Not surprisingly, the Android platform gives developers a wide range of ways to make use of this Internet access. Some offer high-level access, such as the integrated WebKit browser component (`WebView`) we saw in an earlier chapter. If you want, you can drop all the way down to using raw sockets. Or, in between, you can leverage APIs — both on-device and from 3rd-party JARs — that give you access to specific protocols: HTTP, XMPP, SMTP, and so on.

The emphasis of this book is on the higher-level forms of access: the WebKit component and Internet-access APIs, as busy coders should be trying to reuse existing components versus rolling one's own on-the-wire protocol wherever possible.

DIY HTTP

In many cases, your only viable option for accessing some Web service or other HTTP-based resource is to do the request yourself. The Google-endorsed API for doing this nowadays in Android is to use the classic `java.net` classes for HTTP operation, centered around `HttpUrlConnection`. There is quite a bit of material on this already published, as these classes have been in Java for a long time. The focus here is in showing how this works in an Android context.

Note, however, that you may find it easier to use some HTTP client libraries that handle various aspects of the Internet access for you, as will be described later in this chapter.

A Sample Usage of HttpUrlConnection

This chapter walks through several implementations of a Stack Overflow client application. The app has a single activity, with a single `ListFragment`. The app will load the latest block of Stack Overflow questions tagged with `android`, using the Stack Exchange public API. Those questions will be shown in the list, and tapping on a question will bring up the Web page for that question in the user's default Web browser.

All implementations of the app have the same core UI logic. What differs is in how each handles the Internet access. In this section, we will take a look at the `Internet/HURL` sample project, which uses `HttpUrlConnection` to retrieve the questions from the Stack Exchange Web service API.

Asking Permission

To do anything with the Internet (or a local network) from your app, you need to hold the `INTERNET` permission. This includes cases where you use things like `WebView` — if your *process* needs network access, you need the `INTERNET` permission.

Hence, the manifest for our sample project contains the requisite `<uses-permission>` declaration:

```
<uses-permission android:name="android.permission.INTERNET"/>
```

Creating Your Data Model

The Stack Exchange Web service API returns JSON in response to various queries. Hence, we need to create Java classes that mirror that JSON structure. In particular, many of the examples will be using Google's Gson to populate those data models automatically based upon its parsing of the JSON that we receive from the Web service.

In our case, we are going to use a specific endpoint of the Stack Exchange API, referred to as `/questions` after the distinguishing portion of the path. The

documentation for this endpoint can be found in the Stack Exchange API documentation.

We will examine the URL for the endpoint a bit later in this section.

The results we get for issuing a `GET` request for the URL is a JSON structure (here showing a single question, to keep the listing short):

```
{
  "items": [
    {
      "question_id": 17196927,
      "creation_date": 1371660594,
      "last_activity_date": 1371660594,
      "score": 0,
      "answer_count": 0,
      "title": "ksoap2 failing when in 3G",
      "tags": [
        "android",
        "ksoap2",
        "3g"
      ],
      "view_count": 2,
      "owner": {
        "user_id": 773259,
        "display_name": "SparK",
        "reputation": 513,
        "user_type": "registered",
        "profile_image": "http://www.gravatar.com/avatar/
511b37f7c313984e624dd76e8cb9faa6?d=identicon&r=PG",
        "link": "http://stackoverflow.com/users/773259/spark"
      },
      "link": "http://stackoverflow.com/questions/17196927/ksoap2-failing-when-in-3g",
      "is_answered": false
    }
  ],
  "quota_remaining": 9991,
  "quota_max": 10000,
  "has_more": true
}
```

NOTE: Some of the longer URLs will word-wrap in the book, but they are on a single line in the actual JSON. Honest.

We get back a JSON object, where our questions are found under the name of `items`. `items` is a JSON array of JSON objects, where each JSON object represents a single

question, with fields like `title` and `link`. The question JSON object has an embedded `owner` JSON object with additional information.

We do not necessarily need all of this information. In fact, for this first version of the sample, all we really need are the `title` and `link` of each entry in the `items` array.

The key is that, by default, the data members in our Java data model must *exactly* match the JSON keys for the JSON objects.

So, we have an `Item` class, representing the information from an individual entry in the `items` array:

```
package com.commonsware.android.hurl;

public class Item {
  String title;
  String link;

  @Override
  public String toString() {
    return(title);
  }
}
```

(from Internet/HURL/app/src/main/java/com/commonsware/android/hurl/Item.java)

However, our Web service does not return the `items` array directly. `items` is the key in a JSON object that is the actual JSON returned by Stack Exchange. So, we need another Java class that contains the data members we need from that outer JSON object, here named `SOQuestions` (for lack of a better idea for a name...):

```
package com.commonsware.android.hurl;

import java.util.List;

public class SOQuestions {
  List<Item> items;
}
```

(from Internet/HURL/app/src/main/java/com/commonsware/android/hurl/SOQuestions.java)

Having an `items` data member that is a `List` of `Item` tells GSON that we are expecting the JSON object to be used for `SOQuestions` to have a JSON array, named `items`, where each element in that array should get mapped to `Item` objects.

A Thread for Loading

We need to do the network I/O on a background thread, so we do not tie up the main application thread. To that end, the sample app has a `LoadThread` that loads our questions:

```
package com.commonsware.android.hurl;

import android.util.Log;
import java.io.BufferedReader;
import java.io.IOException;
import java.io.InputStream;
import java.io.InputStreamReader;
import java.net.HttpURLConnection;
import java.net.URL;
import com.google.gson.Gson;
import de.greenrobot.event.EventBus;

class LoadThread extends Thread {
  static final String SO_URL=
      "https://api.stackexchange.com/2.1/questions?"
          + "order=desc&sort=creation&site=stackoverflow&tagged=android";

  @Override
  public void run() {
    try {
      HttpURLConnection c=
          (HttpURLConnection)new URL(SO_URL).openConnection();

      try {
        InputStream in=c.getInputStream();
        BufferedReader reader=
            new BufferedReader(new InputStreamReader(in));
        SOQuestions questions=
            new Gson().fromJson(reader, SOQuestions.class);

        reader.close();

        EventBus.getDefault().post(new QuestionsLoadedEvent(questions));
      }
      catch (IOException e) {
        Log.e(getClass().getSimpleName(), "Exception parsing JSON", e);
      }
      finally {
        c.disconnect();
      }
    }
```

```
    catch (Exception e) {
      Log.e(getClass().getSimpleName(), "Exception parsing JSON", e);
    }
  }
}
```

(from Internet/HURL/app/src/main/java/com/commonsware/android/hurl/LoadThread.java)

`LoadThread`:

- Creates an `HttpUrlConnection` by creating a `URL` for our Stack Exchange API endpoint and opening a connection
- Creates a `BufferedReader` wrapped around the `InputStream` from the HTTP connection
- Parses the JSON we get back from that HTTP request via a `Gson` instance, loading the data into an instance of our `SOQuestions`
- Close the `BufferedReader` (and the `InputStream` by extension)
- Post a `QuestionsLoadedEvent` to greenrobot's `EventBus`, to let somebody know that our questions exist
- Log messages to Logcat in case of errors

`QuestionsLoadedEvent` is a simple wrapper around an `SOQuestions` instance, serving as an event class for use with `EventBus`:

```
package com.commonsware.android.hurl;

public class QuestionsLoadedEvent {
  final SOQuestions questions;

  QuestionsLoadedEvent(SOQuestions questions) {
    this.questions=questions;
  }
}
```

(from Internet/HURL/app/src/main/java/com/commonsware/android/hurl/QuestionsLoadedEvent.java)

A Fragment for Questions

The sample app has a `QuestionsFragment` that should display these loaded questions:

```
package com.commonsware.android.hurl;

import android.app.ListFragment;
```

```
import android.os.Bundle;
import android.text.Html;
import android.view.View;
import android.view.ViewGroup;
import android.widget.ArrayAdapter;
import android.widget.ListView;
import android.widget.TextView;
import java.util.List;
import de.greenrobot.event.EventBus;

public class QuestionsFragment extends ListFragment {
  public interface Contract {
    void onQuestion(Item question);
  }

  @Override
  public void onCreate(Bundle savedInstanceState) {
    super.onCreate(savedInstanceState);

    setRetainInstance(true);
    new LoadThread().start();
  }

  @Override
  public void onResume() {
    super.onResume();
    EventBus.getDefault().register(this);
  }

  @Override
  public void onPause() {
    EventBus.getDefault().unregister(this);
    super.onPause();
  }

  @Override
  public void onListItemClick(ListView l, View v, int position, long id) {
    Item item=((ItemsAdapter)getListAdapter()).getItem(position);

    ((Contract)getActivity()).onQuestion(item);
  }

  public void onEventMainThread(QuestionsLoadedEvent event) {
    setListAdapter(new ItemsAdapter(event.questions.items));
  }

  class ItemsAdapter extends ArrayAdapter<Item> {
    ItemsAdapter(List<Item> items) {
```

```
      super(getActivity(), android.R.layout.simple_list_item_1, items);
    }

    @Override
    public View getView(int position, View convertView, ViewGroup parent) {
      View row=super.getView(position, convertView, parent);
      TextView title=(TextView)row.findViewById(android.R.id.text1);

      title.setText(Html.fromHtml(getItem(position).title));

      return(row);
    }
  }
}
```

(from Internet/HURL/app/src/main/java/com/commonsware/android/hurl/QuestionsFragment.java)

In `onCreate()`, we mark that this fragment should be retained and fork the `LoadThread`. Hence, once we have our questions, our retained fragment will hold onto that model data for us, and we avoid duplicating the `LoadThread` if a configuration change occurs sometime after our fragment was initially created.

In `onResume()` and `onPause()`, we register and unregister from the `EventBus`. Our `onEventMainThread()` method will be called when the `QuestionsLoadedEvent` is raised by `LoadThread`, and there we hold onto the loaded questions and populate the `ListView`. We use an `ItemsAdapter`, which knows how to render an `Item` as a simple `ListView` row showing the question title. The `ItemsAdapter` uses `Html.fromHtml()` to populate the `ListView` rows, not because Stack Overflow hands back titles with HTML tags, but because Stack Overflow hands back titles with HTML *entity references*, and `Html.fromHtml()` should handle many of those.

And, in `onListItemClick()`, we find the `Item` associated with the row that the user clicked upon, then call an `onQuestion()` method on our hosting activity. That activity needs to implement the `Contract` interface, so we can call the `onQuestion()` method on whatever activity happens to host this fragment.

An Activity for Orchestration

`MainActivity` sets up the fragment in `onCreate()` and handles the click events in `onQuestion()`:

```
package com.commonsware.android.hurl;

import android.app.Activity;
```

```
import android.content.Intent;
import android.net.Uri;
import android.os.Bundle;
import de.greenrobot.event.EventBus;

public class MainActivity extends Activity
  implements QuestionsFragment.Contract {
  @Override
  protected void onCreate(Bundle savedInstanceState) {
    super.onCreate(savedInstanceState);

    if (getFragmentManager().findFragmentById(android.R.id.content) == null) {
      getFragmentManager().beginTransaction()
                          .add(android.R.id.content,
                               new QuestionsFragment()).commit();
    }
  }

  @Override
  public void onQuestion(Item question) {
    startActivity(new Intent(Intent.ACTION_VIEW,
                             Uri.parse(question.link)));
  }
}
```

(from Internet/HURL/app/src/main/java/com/commonsware/android/hurl/MainActivity.java)

Hence, `MainActivity` is serving in an orchestration role. `QuestionsFragment` is a local controller, handling direct events raised by its widgets (a `ListView`). `MainActivity` is responsible for handling events that transcend an individual fragment — in this case, it starts a browser to view the clicked-upon question.

The result is a simple `ListView` showing questions:

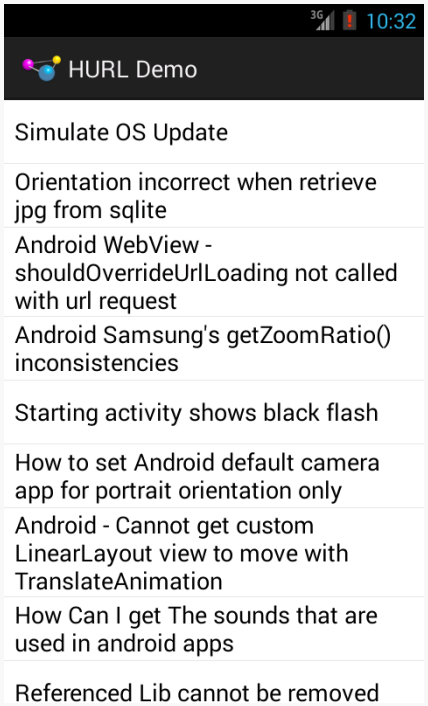

Figure 300: HURLDemo, Showing Stack Overflow Questions

What Android Brings to the Table

Google has augmented `HttpUrlConnection` to do more stuff to help developers. Notably:

- It automatically uses GZip compression on requests, adding the appropriate HTTP header and automatically decompressing any compressed responses (added in Android 2.3)
- It uses Server Name Indication to help work with several HTTPS hosts sharing a single IP address
- API Level 13 (Android 4.0) added an `HttpResponseCache` implementation of the `java.net.ResponseCache` base class, that can be installed to offer transparent caching of your HTTP requests.

Also, courtesy of some third-party code (OkHttp) that we will discuss shortly, `HttpUrlConnection` also supports the SPDY protocol and HTTP/2 for accelerating Web content distribution over SSL as of Android 4.4.

Testing with StrictMode

`StrictMode`, mentioned in the chapter on files, can also report on performing network I/O on the main application thread. More importantly, on Android 3.0 and higher, by default, Android will crash your app with a `NetworkOnMainThreadException` if you try to perform network I/O on the main application thread.

Hence, it is generally a good idea to test your app, either using `StrictMode` yourself or using a suitable emulator, to make sure that you are not performing network I/O on the main application thread.

What About HttpClient?

Android also contains — or used to contain – a mostly-complete copy of version 4.0.2beta of the Apache HttpClient library. Many developers use this, as they prefer the richer API offered by this library over the somewhat more clunky approach used by `java.net`. And, truth be told, this was the more stable option prior to Android 2.3.

There are a few reasons why this is no longer recommended, for Android 2.3 and beyond:

- The core Android team is better able to add capabilities to the `java.net` implementation while maintaining backwards compatibility, because its API is more narrow.
- The problems previously experienced on Android with the `java.net` implementation have largely been fixed.
- The Apache HttpClient project continuously evolves its API. This means that Android will continue to fall further and further behind the latest-and-greatest from Apache, as Android insists on maintaining the best possible backwards compatibility and therefore cannot take on newer-but-different HttpClient versions.
- Google officially deprecated this API in Android 5.1.
- Google officially removed this API in Android 6.0.

If you have legacy code that uses the HttpClient API, please consider using Apache's standalone edition of HttpClient for Android.

And, if you cannot do any of that, and you are using Gradle for your builds (e.g., you are using Android Studio's default settings), you can add `useLibrary 'org.apache.http.legacy'` to the `android` closure to give you access to Android's stock HttpClient API:

```
android {
    useLibrary 'org.apache.http.legacy'
    // other settings go here
}
```

However, usually, using a standalone edition should be reasonably practical.

For example, the `Internet/HttpClient` sample project is a clone of the `HttpURLConnection` sample from earlier in this chapter, revised to use HttpClient. More specifically, it uses the `cz.msebera.android` packaging of Apache HttpClient for Android:

```
apply plugin: 'com.android.application'

dependencies {
    implementation 'de.greenrobot:eventbus:2.2.1'
    implementation 'com.google.code.gson:gson:2.8.0'
    implementation 'cz.msebera.android:httpclient:4.4.1.1'
}

android {
    compileSdkVersion 25
    buildToolsVersion '26.0.2'

    defaultConfig {
        minSdkVersion 16
        targetSdkVersion 25
    }
}
```

(from Internet/HttpClient/app/build.gradle)

The classes are all the same as in the equivalent Apache HttpClient code, except that `org.apache` is replaced by `cz.msebera.android`.

The code that you might have used with Android's built-in HttpClient will not directly work on newer versions of Apache's HttpClient, due to API differences. However, it is fairly close in most common places, requiring slight modifications, usually to improve the API.

For example, here is the `LoadThread` class from before, revised to use HttpClient:

```
package com.commonsware.android.httpclient;

import android.util.Log;
import com.google.gson.Gson;
import java.io.IOException;
import cz.msebera.android.httpclient.client.HttpClient;
import cz.msebera.android.httpclient.client.methods.HttpGet;
import cz.msebera.android.httpclient.impl.client.BasicResponseHandler;
import cz.msebera.android.httpclient.impl.client.HttpClientBuilder;
import cz.msebera.android.httpclient.impl.conn.PoolingHttpClientConnectionManager;
import de.greenrobot.event.EventBus;

class LoadThread extends Thread {
  static final String SO_URL=
      "https://api.stackexchange.com/2.1/questions?"
          + "order=desc&sort=creation&site=stackoverflow&tagged=android";

  @Override
  public void run() {
    try {
      HttpClient client=HttpClientBuilder.create()
        .setConnectionManager(
          new PoolingHttpClientConnectionManager())
        .build();
      HttpGet get=new HttpGet(SO_URL);

      try {
        String result=client.execute(get, new BasicResponseHandler());
        SOQuestions questions=
            new Gson().fromJson(result, SOQuestions.class);

        EventBus.getDefault().post(new QuestionsLoadedEvent(questions));
      }
      catch (IOException e) {
        Log.e(getClass().getSimpleName(), "Exception parsing JSON", e);
      }
    }
    catch (Exception e) {
      Log.e(getClass().getSimpleName(), "Exception parsing JSON", e);
    }
  }
}
```

(from Internet/HttpClient/app/src/main/java/com/commonsware/android/httpclient/LoadThread.java)

We start by getting an `HttpClient` instance from an `HttpClientBuilder`. Particularly if you use the `PoolingHttpClientConnectionManager`, as shown here, the `HttpClient` instance is designed to be shared among multiple threads, and so could be used as a singleton. Here, we only use it once, so it is merely a local variable in the `run()` method.

From there, we:

- Create an `HttpGet` object to represent the Stack Exchange API `GET` request
- Tell the `HttpClient` to `execute()` the `HttpGet`, passing the response through a `BasicResponseHandler`, which returns a `String` containing our JSON (assuming there is no server error)
- Pass that `String` through Gson to get our `SOQuestions`, much as before

HTTP via DownloadManager

If your objective is to download some large file, you may be better served by using the `DownloadManager` added to Android 2.3, as it handles a lot of low-level complexities for you. For example, if you start a download on WiFi, and the user leaves the building and the device fails over to some form of mobile data, you need to reconnect to the server and either start the download again or use some content negotiation to pick up from where you left off. `DownloadManager` handles that.

However, `DownloadManager` is dependent upon some broadcast `Intent` objects, a technique we have not discussed yet, so we will delay covering `DownloadManager` until later in the book.

Using Third-Party JARs

To some extent, the best answer is to not write the code yourself, but rather use some existing JAR that handles both the Internet I/O and any required data parsing. This is commonplace when accessing public Web services — either because the firm behind the Web service has released a JAR, or because somebody in the community has released a JAR for that Web service.

Examples include:

- Using JTwitter to access Twitter's API
- Using Amazon's JAR to access various AWS APIs, including S3, SimpleDB, and SQS
- Using the Dropbox SDK for accessing DropBox folders and files

However, beyond the classic potential JAR problems, you may encounter another when it comes to using JARs for accessing Internet services: versioning. For example:

- JTwitter bundles the `org.json` classes in its JAR, which will be superseded by Android's own copy, and if the JTwitter version of the classes have a different API, JTwitter could crash.

- Libraries dependent upon HttpClient might be dependent upon a version with a different API (e.g., 4.1.1) than is in Android (4.0.2 beta).

Try to find JARs that have been tested on Android and are clearly supported as such by their author. Lacking that, try to find JARs that are open source, so you can tweak their implementation if needed to add Android support.

Later in this chapter, we will review another class of third-party JARs, ones that are more general-purpose than things like JTwitter, but still offer to simplify HTTP processing.

SSL

Of course, if you are thinking about HTTP, you really should be thinking about HTTPS — SSL-encrypted HTTP operations.

Normally, SSL "just works", by using an `https://` URL. Hence, typically, there is little that you need to do to enable simple encryption.

However, there are other aspects of SSL to consider, including:

- What if the server is not using an SSL certificate that Android will honor, such as a self-signed certificate?
- What about man-in-the-middle attacks, hacked certificate authorities, and the like?

The trails contain a chapter dedicated to SSL that you are encouraged to read, so that this chapter does not get crazy-long.

Using HTTP Client Libraries

Often times, writing Internet access code is a pain in various body parts.

Not surprisingly, there are a variety of third-party libraries designed to assist with this. Some are designed to provide access to a specific API, such as the ones mentioned earlier in this chapter. However, others are more general-purpose, designed to make writing HTTP operations a bit easier, by handling things like:

- Retries (e.g., device failed over from WiFi to mobile data mid-transaction)

- Threading (e.g., handling doing the Internet work on a background thread for you)
- Data parsing and marshaling, for well-known formats (e.g., JSON)

In this section, we will look at three libraries that exemplify this approach: OkHttp, Retrofit, and Picasso. Later, we will see other libraries that you might wish to investigate, including Google's own Volley HTTP client API.

OkHttp

OkHttp uses a modified clone of the standard `HttpUrlConnection` to offer many performance improvements. Most notable is its support for SPDY, a Google sponsored enhanced version of HTTP, going beyond classic HTTP "keep-alive" support to allow for many requests and responses to be delivered over the same socket connection. This, in turn, evolved into HTTP/2. Many Google APIs are served by SPDY- or HTTP/2-capable servers, and HTTP/2 is gaining popularity overall.

Beyond that, OkHttp wraps up common HTTP performance-improvement patterns, such as GZIP compression, response caching, and connection pooling. It also is more aware of "real world" connection issues, like mis-configured proxy servers and the like.

Note that a version of OkHttp lies behind the standard implementation of `HttpUrlConnection` in Android 4.4 and higher — this is where Android's SPDY support comes from.

OkHttp has changed over the years. OkHttp came to prominence in its 1.x and 2.x versions, with a reasonably stable API. OkHttp 3.x is the current generation, with a richer but slightly different API.

OkHttp 2.x

The `Internet/OkHttp` sample project is a clone of the Stack Overflow sample shown earlier in this chapter. The original sample used `HttpURLConnection` to download the Stack Exchange Web service data. This revised sample replaces that with OkHttp.

First, we need to add a dependency on OkHttp to our `app/` module's `build.gradle` file:

```
dependencies {
    implementation 'de.greenrobot:eventbus:2.4.0'
    implementation 'com.google.code.gson:gson:2.8.0'
    implementation 'com.squareup.okhttp:okhttp:2.4.0'
}
```

(from Internet/OkHttp/app/build.gradle)

OkHttp offers two basic flavors of HTTP API: synchronous and asynchronous. With a synchronous call, the call blocks until the HTTP I/O is completed (or, at least, the headers are downloaded). With an asynchronous call, that initial pulse of network I/O is handled on a background thread. The general rule of thumb is:

- If you can work with the raw HTTP response, and it's short, use the asynchronous API, as it saves you from having to fuss with your own thread
- If the response may be long or requires significant post-retrieval work (e.g., parsing), use your own background thread and use the synchronous API

In our case, we need to parse the JSON using Gson, and so the second approach is the better answer. This has the side benefit of limiting our Java changes to only be in `LoadThread`:

```
package com.commonsware.android.okhttp;

import android.util.Log;
import com.google.gson.Gson;
import com.squareup.okhttp.OkHttpClient;
import com.squareup.okhttp.Request;
import com.squareup.okhttp.Response;
import java.io.BufferedReader;
import java.io.Reader;
import de.greenrobot.event.EventBus;

class LoadThread extends Thread {
  static final String SO_URL=
      "https://api.stackexchange.com/2.1/questions?"
          + "order=desc&sort=creation&site=stackoverflow&tagged=android";

  @Override
  public void run() {
    try {
      OkHttpClient client=new OkHttpClient();
      Request request=new Request.Builder().url(SO_URL).build();
      Response response=client.newCall(request).execute();

      if (response.isSuccessful()) {
```

```
        Reader in=response.body().charStream();
        BufferedReader reader=new BufferedReader(in);
        SOQuestions questions=
            new Gson().fromJson(reader, SOQuestions.class);

        reader.close();

        EventBus.getDefault().post(new QuestionsLoadedEvent(questions));
      }
      else {
        Log.e(getClass().getSimpleName(), response.toString());
      }
    }
    catch (Exception e) {
      Log.e(getClass().getSimpleName(), "Exception parsing JSON", e);
    }
  }
}
```

(from Internet/OkHttp/app/src/main/java/com/commonsware/android/okhttp/LoadThread.java)

Our revised `run()` method creates an instance of `OkHttpClient`. This is your gateway for performing HTTP requests.

An individual request, not surprisingly, is represented by a `Request` object, usually created using a `Request.Builder`. The `url()` method on the `Builder` is where you supply the URL to be retrieved via a `GET` request. There are other methods on `Builder`, such as `post()`, which supplies additional data for the request and converts it into a `POST` request.

To actually perform the synchronous request, call `newCall().execute()` on the `OkHttpClient`, passing in the `Request` to the `newCall()` method. This gives you a `Response` object, which should return `true` from `isSuccessful()`. `false` would indicate some sort of a problem, such as an HTTP 404 response code.

Given a successful `Response`, you can get at the body of the response via a `body()` method. This returns a `ResponseBody`, which offers three main ways to get at the response body itself:

- `string()` returns the entire response as a `String`, which is only really suitable for short text responses
- `byteStream()` returns an `InputStream` on the raw bytes of the response
- `charStream()`, despite its name, returns a `Reader` on the characters of the response, taking into account the response's character encoding (e.g., UTF-8)

Here, we use `charStream()` to get a `Reader`, which we then wrap in a `BufferedReader`. The rest of the `run()` method is pretty much the same as the original, asking Gson to parse the response and posting a `QuestionsLoadedEvent` to get the questions over to our fragment on the main application thread.

OkHttp3

For simple projects like this one, there is no substantial change required for OkHttp3. The `Internet/OkHttp3` sample project is a clone of the `Internet/OkHttp` project, adjusted to work with OkHttp3. There are only two such adjustments:

- Update `build.gradle` to point to the `com.squareup.okhttp3` artifact:

```
dependencies {
    implementation 'de.greenrobot:eventbus:2.4.0'
    implementation 'com.google.code.gson:gson:2.8.2'
    implementation 'com.squareup.okhttp3:okhttp:3.9.0'
}
```

(from Internet/OkHttp3/app/build.gradle)

- Update the `import` statements to use `okhttp3` as a package, instead of `com.squareup.okhttp`

Because the artifact and imports are both different, it is technically possible to have *both* OkHttp 2.x and 3.x in a project at one time. That is not a great long-term solution, but it may prove useful, particularly if you are using other libraries that happen to depend on different generations of OkHttp.

OkHttp 1.x and 2.x supported compatibility layers that modeled `HttpURLConnection` and Apache's `HttpClient`. These have been discontinued with OkHttp3.

Retrofit

Many times, when working with HTTP requests, our needs are fairly simple: just retrieve some JSON (or other structured data, such as XML) from some Web service, or perhaps upload some JSON to that Web service.

Retrofit is designed to simplify this, by handling the data parsing and marshaling for us, along with the HTTP operations and (optionally) background threading. We are left with a fairly natural-looking Java API to send/receive Java objects to/from the

Web service. Retrofit accomplishes this through the cunning use of annotations, reflection, and, where available, OkHttp itself.

There are two major generations of the Retrofit API: 1.x and 2.x. Both share the same objectives and general capabilities. Retrofit 1.x was fairly popular, and so you will see a fair bit of code still using that, even though new development should strongly consider the newer 2.x generation. In this section, we will review both, looking first at 1.x and then seeing what changed in 2.x.

Retrofit 1.x

To demonstrate Retrofit 1.x (and set the stage for Retrofit 2.x), let's review the `HTTP/Retrofit` sample project. This project is a clone of the preceding one, this time using Retrofit for retrieving and parsing our Stack Overflow questions.

Note that Stack Overflow happens to use JSON as its data format, which works nicely with Retrofit, as JSON is its default data format. However, you can supply your own conversion logic, to convert data to/from other formats, such as XML or Protocol Buffers.

Dependencies

The `com.squareup.retrofit:retrofit` artifact is used for Retrofit 1.x. The last published release version of Retrofit 1.x was 1.9.0, and this project includes that dependency:

```
dependencies {
    implementation 'com.squareup.retrofit:retrofit:1.9.0'
}
```

(from HTTP/Retrofit/app/build.gradle)

By default, Retrofit uses Google's Gson for its JSON parsing. The `com.squareup.retrofit:retrofit` artifact has Gson as a dependency, so requiring `com.squareup.retrofit:retrofit` will also pull in a compatible version of Gson.

Creating Your Service Interface

The first thing we need is to tell Retrofit more about where our JSON is coming from. To do this, we need to create a Java interface with some specific Retrofit-supplied annotations, documenting:

- the HTTP operations that we wish to perform
- the path (and, if needed, query parameters) to apply an HTTP operation to
- the per-request data to configure the HTTP operation, such as the dynamic portions of the path for a REST-style API, or additional query parameters to attach to the URL
- what object should be used for pouring the HTTP response into

For example, let's take a look at `StackOverflowInterface`, our interface for making a query of Stack Exchange's API to get questions from Stack Overflow:

```
package com.commonsware.android.retrofit;

import retrofit.Callback;
import retrofit.http.GET;
import retrofit.http.Query;

public interface StackOverflowInterface {
  @GET("/2.1/questions?order=desc&sort=creation&site=stackoverflow")
  void questions(@Query("tagged") String tags, Callback<SOQuestions> cb);
}
```

(from HTTP/Retrofit/app/src/main/java/com/commonsware/android/retrofit/StackOverflowInterface.java)

Each method in the interface should have an annotation identifying the HTTP operation to perform, such as `@GET` or `@POST`. The parameter to the annotation is the path for the request and any fixed query parameters. In our case, we are using the path documented by Stack Exchange for retrieving questions (`/2.1/questions`), plus some fixed query parameters:

- `order` for whether the results should be ascending (`asc`) or descending (`desc`)
- `sort` to indicate how the questions should be sorted, such as `creation` to sort by time when the question was posted
- `site` to indicate what Stack Exchange site we are querying (e.g., `stackoverflow`)

The method name can be whatever you want.

If you have additional query parameters that vary dynamically, you can use the `@Query` annotation on `String` parameters to have them be added to the end of the URL. In our case, the `tagged` query parameter will be added with whatever the `tags` parameter is to our `questions()` method.

Similarly, you can use `{name}` placeholders for path segments, and replace those at runtime via `@Path`-annotated parameters to the method.

To get results back, and indicate the data type for those results, you have two choices:

1. Have the method return the data type you wish, in which case when we eventually call this method, the HTTP operation will be performed synchronously, blocking our method call
2. Pass a `Callback` parameter, declared with the desired data type (e.g., `SOQuestions`), in which case when we eventually call this method, the HTTP operation will be performed on a background thread, with the results delivered to us asynchronously via a custom `Callback` implementation that we will supply

In this case, we are electing to let Retrofit handle the threading for us, so we supply a `Callback` and have the method return `void`.

Curiously, we will never create an implementation of the `StackOverflowInterface` ourselves. Instead, Retrofit generates one for us, with code that implements our requested behaviors.

Creating the RestAdapter

To use this generated `StackOverflowInterface`, and to actually perform these operations, we need to create an instance of a `RestAdapter`. Usually, you will do this via a `RestAdapter.Builder`, to configure what you want done.

The biggest thing you will provide to `RestAdapter.Builder` is the server tied to these HTTP operations. Calling `setEndpoint()` allows you to specify the scheme, host, and port to be attached to the rest of the URL, coming from your interface. For example, we need to make our requests of the `https://api.stackexchange.com` server, so we have:

```
    RestAdapter restAdapter=
        new RestAdapter.Builder().setEndpoint("https://api.stackexchange.com")
                                 .build();
```

(from HTTP/Retrofit/app/src/main/java/com/commonsware/android/retrofit/QuestionsFragment.java)

Other methods on `RestAdapter.Builder` include:

- `setConverter()`, if your payloads are not in JSON format, but something else
- `setExecutors()`, to provide `Executor` objects (e.g., instances of `ThreadPoolExecutor`) to be used for requests and callbacks
- `setLog()` and `setDebug()` for controlling log output

When you are done configuring the `RestAdapter.Builder`, call `build()` to get the resulting `RestAdapter`.

Making Requests

Given a configured `RestAdapter`, you can retrieve an implementation of your API interface by calling the `create()` method:

```
    StackOverflowInterface so=
        restAdapter.create(StackOverflowInterface.class);
```

(from HTTP/Retrofit/app/src/main/java/com/commonsware/android/retrofit/QuestionsFragment.java)

You can then use the resulting interface-typed object no differently than you would any other Java object, despite the fact that you never wrote an implementation of that interface yourself.

In our case, we can call the `questions()` method, supplying the tag (or tags) from which we wish to receive recent questions:

```
    so.questions("android", this);
```

(from HTTP/Retrofit/app/src/main/java/com/commonsware/android/retrofit/QuestionsFragment.java)

The second parameter to `questions()` is an implementation of `Callback`, to receive asynchronous results from our HTTP `GET` request. `Callback` requires two methods, `success()` and `failure()`. `success()` takes two parameters: the data type you indicated in the interface (e.g., `SOQuestions`) representing the parsed results of the HTTP request, and a `Response` object containing other information from the HTTP response, such as headers:

```
@Override
public void success(SOQuestions questions, Response response) {
  setListAdapter(new ItemsAdapter(questions.items));
}
```

(from HTTP/Retrofit/app/src/main/java/com/commonsware/android/retrofit/QuestionsFragment.java)

Here, we update our `ListView` with an `ItemsAdapter` based upon the received questions.

`failure()` takes a single parameter, an instance of `RetrofitError`, which is an `Exception` providing details of something that went wrong in the HTTP request (e.g., authorization was denied). You can handle that no differently than you might other exceptions from elsewhere in your app, to let the user know that something went wrong. In this case, we take the crude-but-easy approach of showing a `Toast` and logging the details to Logcat:

```
  @Override
  public void failure(RetrofitError exception) {
    Toast.makeText(getActivity(), exception.getMessage(),
                   Toast.LENGTH_LONG).show();
    Log.e(getClass().getSimpleName(),
          "Exception from Retrofit request to StackOverflow", exception);
  }
```

(from HTTP/Retrofit/app/src/main/java/com/commonsware/android/retrofit/QuestionsFragment.java)

Retrofit 2.x

The `HTTP/Retrofit2` sample project is a clone of the preceding one, updated to use Retrofit 2.x (along with 3.x of greenrobot's EventBus).

There were a number of changes made in Retrofit 2.x, starting with the dependency. With Retrofit 1.x, Retrofit would automatically pull in a compatible version of Gson, and it would do so all the time (unless you took specific steps in Gradle to block that). In Retrofit 2.x, the parsing logic is now handled by plugins, as Retrofit 2.x has direct support for a wide range of parsers, for JSON (e.g., Gson, Jackson), XML (e.g., SimpleXML), and Protocol Buffers. If you request the artifact for one of those plugins, that artifact will pull in a compatible version of both Retrofit 2.x and the associated "converter" code (e.g., Gson). To allow apps to support both Retrofit 1.x and 2.x in the same project, Retrofit 2.x moved to the `com.squareup.retrofit2` group ID, with various artifacts in there. So, this revised sample app pulls in the `converter-gson` artifact, to get Retrofit with Gson support:

```
dependencies {
    implementation 'com.squareup.retrofit2:converter-gson:2.1.0'
}
```

(from HTTP/Retrofit2/app/build.gradle)

Also, to allow projects to have both Retrofit 1.x and 2.x, all of the Retrofit 2.x classes are in a `retrofit2` Java package, distinct from the `retrofit` package used for Retrofit 1.x.

With Retrofit 1.x, our service interface would use two different method signatures for synchronous and asynchronous operation. Synchronous methods would return the desired object type (e.g., `SOQuestions`), while the asynchronous methods would return `void` and take a `Callback` as a parameter. Retrofit 2.x simplifies this, having all service interface method signatures return a `Call` object of the desired type:

```
package com.commonsware.android.retrofit;

import retrofit2.Call;
import retrofit2.Callback;
import retrofit2.http.GET;
import retrofit2.http.Query;

public interface StackOverflowInterface {
  @GET("/2.1/questions?order=desc&sort=creation&site=stackoverflow")
  Call<SOQuestions> questions(@Query("tagged") String tags);
}
```

(from HTTP/Retrofit2/app/src/main/java/com/commonsware/android/retrofit/StackOverflowInterface.java)

For synchronous work, you `execute()` the `Call`; for asynchronous work, you `enqueue()` the `Call`, providing a `Callback` object as a parameter to `enqueue()`.

Retrofit 1.x had a `RestAdapter` that you would use to configure the general Retrofit behavior, then use `create()` to get implementations of the service interface. Retrofit 2.x uses a similar system, but it is now a `Retrofit` object, created via a `Retrofit.Builder`:

```
  @Override
  public View onCreateView(LayoutInflater inflater,
                           ViewGroup container,
                           Bundle savedInstanceState) {
    View result=
        super.onCreateView(inflater, container, savedInstanceState);

    setRetainInstance(true);

    Retrofit retrofit=
      new Retrofit.Builder()
        .baseUrl("https://api.stackexchange.com")
        .addConverterFactory(GsonConverterFactory.create())
```

```
      .build();
  StackOverflowInterface so=
    retrofit.create(StackOverflowInterface.class);

  so.questions("android").enqueue(this);

  return(result);
}
```

(from HTTP/Retrofit2/app/src/main/java/com/commonsware/android/retrofit/QuestionsFragment.java)

Note the call to `addConverterFactory()` on the `Retrofit.Builder`. Since Retrofit 2.x no longer assumes that you want to use any particular parser, you have to specifically supply an instance of a `Converter`. `GsonConverterFactory` is in the `converter-gson` artifact and gives us a `GsonConverter` that we can create via `create()` on the factory.

The `Callback` interface is also slightly different, with `onResponse()` and `onFailure()` methods replacing the Retrofit 1.x `success()` and `failure()` methods:

```
@Override
public void onResponse(Call<SOQuestions> call,
                       Response<SOQuestions> response) {
  setListAdapter(new ItemsAdapter(response.body().items));
}

@Override
public void onFailure(Call<SOQuestions> call, Throwable t) {
  Toast.makeText(getActivity(), t.getMessage(),
    Toast.LENGTH_LONG).show();
  Log.e(getClass().getSimpleName(),
    "Exception from Retrofit request to StackOverflow", t);
}
```

(from HTTP/Retrofit2/app/src/main/java/com/commonsware/android/retrofit/QuestionsFragment.java)

In `onResponse()`, to get the results of the Retrofit request, call `body()` on the supplied `Response` object.

So, overall, Retrofit 2.x does the same sort of work as does Retrofit 1.x, just with a somewhat altered set of artifacts and APIs.

Picasso

Sometimes, what you want to download is not JSON, or XML, or any sort of structured data.

Sometimes, it is an image.

For example, Stack Overflow users have avatars. In our sample app, it might be nice to display the avatar of the user who asked the question.

Picasso is a library from Square that is designed to help with asynchronously loading images, whether those images come from HTTP requests, local files, a `ContentProvider`, etc. In addition to doing the loading asynchronously, Picasso simplifies many operations on those images, such as:

- Caching the results in memory (or optionally on disk for HTTP requests)
- Displaying placeholder images while the real images are being loaded, and displaying error images if there was a problem in loading the image (e.g., invalid URL)
- Transforming the image, such as resizing or cropping it to fit a certain amount of space
- Loading the images directly into an `ImageView` of your choice, even handling cases where that `ImageView` is recycled (e.g., part of a row in a `ListView`, where the user scrolled while an image for that `ImageView` was still loading, and now *another* image is destined for that same `ImageView` when the row was recycled)

The `HTTP/Picasso` sample application extends the Retrofit one to download the avatar image of the person asking the question, displaying it in the `ListView` along with the question title.

Downloading and Installing Picasso

Picasso can be downloaded as a small JAR from the aforementioned Web site. Android Studio users can just add a dependency for `com.squareup.picasso:picasso:...` for some version denoted by `...`, and it will pull down all other dependencies needed by Picasso:

```
dependencies {
    implementation 'com.squareup.picasso:picasso:2.5.2'
    implementation 'com.squareup.retrofit:retrofit:1.9.0'
}
```

(from HTTP/Picasso/app/build.gradle)

Updating the Model

Our original data model did not include information about the owner. Hence, we need to augment our data model, so Retrofit pulls that information out of the Stack Exchange JSON and makes it available to us.

To that end, we now have an `Owner` class, holding onto the one piece of information we need about the owner: the URL to the avatar (a.k.a., "profile image"):

```
package com.commonsware.android.picasso;

import com.google.gson.annotations.SerializedName;

public class Owner {
  @SerializedName("profile_image") String profileImage;
}
```

(from HTTP/Picasso/app/src/main/java/com/commonsware/android/picasso/Owner.java)

The JSON key for this in the Stack Exchange API is `profile_image`, and underscores are not the conventional way of separating words in a Java data member. Java samples usually use "camelCase" instead. The default behavior of Retrofit would require us to name our data member `profile_image` to match the JSON.

However, under the covers, Retrofit is using Google's Gson to do the mapping from JSON to objects. Gson supports a `@SerializedName` annotation, to indicate the JSON key to use for this data member. This allows us to give the data member the more natural name of `profileImage`, by using `@SerializedName("profile_image")` to teach Gson how to populate it properly.

(The author would like to thank Alec Holmes for his assistance with the Gson support)

Our `Item` class now has an `Owner`, named `owner`, since the owner data is in the `owner` key of an item's JSON object:

```
package com.commonsware.android.picasso;

public class Item {
  String title;
  Owner owner;
  String link;

  @Override
```

```
  public String toString() {
    return(title);
  }
}
```

(from HTTP/Picasso/app/src/main/java/com/commonsware/android/picasso/Item.java)

Those two changes are sufficient for Retrofit to give us our URL to be able to download the image.

Requesting the Images

Using Picasso is extremely simple, as it offers a fluent interface that allows us to set up a request in a single Java statement.

The statement begins with a call to the static `with()` method on the `Picasso` class, where we supply a `Context` (such as our activity) for Picasso to use. The statement *ends* with a call to `into()`, indicating the `ImageView` into which Picasso should load an image. In between those calls, we can chain other calls, as `with()` and most other methods on a `Picasso` object return the `Picasso` object itself.

So, we can do something like:

```
      Picasso.with(getActivity()).load(item.owner.profileImage)
             .fit().centerCrop()
             .placeholder(R.drawable.owner_placeholder)
             .error(R.drawable.owner_error).into(icon);
```

(from HTTP/Picasso/app/src/main/java/com/commonsware/android/picasso/QuestionsFragment.java)

Here, we:

- Indicate that we want to `load()` an image found at a certain URL, identified by the `profileImage` data member of the `Owner` inside an `Item` referred to as `item`
- Say that we want to `fit()` the image to our target `ImageView`
- Specify that the image should be resized using `centerCrop()` rules, to center the image within the desired size (if it is smaller on one or both axes) and to crop the image (if it is larger on one or both axes)
- Indicate that we want to put a certain drawable resource as the `placeholder()` image to show in the `ImageView` while the loading is going on in the background

- State that we want to show a certain drawable resource in the `ImageView` in case of an `error()` when the image was being loaded

And that's it. Picasso will go off, download the image, and pour it into the `ImageView` when it is ready (and resized).

The Rest of the Story

That bit of Picasso code is in a new `getView()` method on our `ItemsAdapter`:

```
class ItemsAdapter extends ArrayAdapter<Item> {
  ItemsAdapter(List<Item> items) {
    super(getActivity(), R.layout.row, R.id.title, items);
  }

  @Override
  public View getView(int position, View convertView, ViewGroup parent) {
    View row=super.getView(position, convertView, parent);
    Item item=getItem(position);
    ImageView icon=(ImageView)row.findViewById(R.id.icon);

    Picasso.with(getActivity()).load(item.owner.profileImage)
           .fit().centerCrop()
           .placeholder(R.drawable.owner_placeholder)
           .error(R.drawable.owner_error).into(icon);

    TextView title=(TextView)row.findViewById(R.id.title);

    title.setText(Html.fromHtml(getItem(position).title));

    return(row);
  }
}
```

(from HTTP/Picasso/app/src/main/java/com/commonsware/android/picasso/QuestionsFragment.java)

We have created our own row layout (`res/layout/row.xml`), consisting of an `ImageView` and a `TextView`. We have `ArrayAdapter` inflate or recycle our row, retrieve the `Item` for this row, retrieve the `ImageView` out of the row, use Picasso to start loading the real image, fill in the HTML-entity-aware text into the `TextView`, and then return our updated row. By the time we return the row, Picasso will have already loaded the placeholder image, which is what the user will initially see, while we download the real image.

The result is that we now have icons next to each of our question titles:

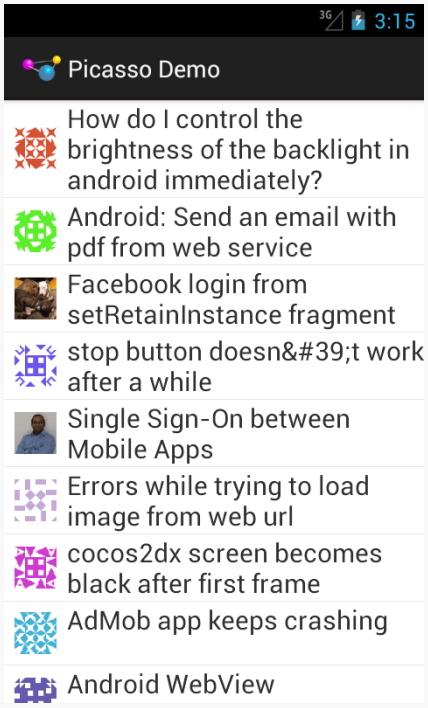

Figure 301: The Picasso Demo App

Volley

At the Google I|O 2013 conference, there was a session about Volley, an HTTP client library created by Google and used by internal apps, such as the Play Store. Volley can be thought of as a superset of Retrofit plus Picasso, minus Picasso's non-HTTP image loading facilities.

On the plus side, Volley *is* such a superset and therefore a single code base can be used to replace multiple libraries. Also, given Volley's use by Google, one imagines that this code has been applied to the widest range of possible devices. And, in early 2016, Volley finally started being distributed as an artifact that we can add to our Android Studio projects via a simple `implementation` statement.

However, there is no documentation beyond that I|O video and a training module. There is no support mechanism, except perhaps via ad-hoc social media inquiries and general support sites (e.g., Stack Overflow).

All that being said, Volley is still rather popular, so let's see how one can use it in an Android project. Specifically, the `HTTP/Volley` sample application is based off of the

Picasso sample, migrated over to use Volley instead of the combination of Picasso and Retrofit.

Getting Volley

It used to be that half the battle was just getting Volley in the first place. For years, Google only gave us a dump of source code in the Android Open Source Project, rather than a proper artifact.

However, in early 2016, Google quietly released a Volley artifact, so you can add it to your `dependencies`:

```
dependencies {
  implementation 'com.android.volley:volley:1.0.0'
}
```

Requests and Queues

Volley's primary API is via a class called `RequestQueue`. As the name suggests, it queues requests, whether those requests are for images, strings, JSON structures, or whatever. A request – in the form of a `Request` instance – embodies the URL to be retrieved, any additional information (e.g., extra HTTP headers), and the rules for interpreting the response received from the server.

Under the covers, `RequestQueue` maintains a thread pool for processing those requests. You can optionally configure this thread pool, indicating how many threads it should have and so on. You can also optionally configure how responses should be cached and the actual HTTP stack to be used for doing the network I/O. By default, on modern versions of Android, Volley delegates to `HttpUrlConnection`.

Making a Manager

Retrofit and Picasso manage application-level thread pools and caches for you, via supplied singletons. Alas, Volley does not. While this provides flexibility, it does mean that you need your own singleton wrapper around a `RequestQueue`. In the sample project, we have `VolleyManager` for that:

```
package com.commonsware.android.volley;

import android.content.Context;
import android.widget.ImageView;
```

```
import com.android.volley.Request;
import com.android.volley.RequestQueue;
import com.android.volley.toolbox.ImageLoader;
import com.android.volley.toolbox.Volley;

public class VolleyManager {
  private static volatile VolleyManager INSTANCE;
  private final RequestQueue queue;
  private final ImageLoader imageLoader;

  synchronized static VolleyManager get(Context ctxt) {
    if (INSTANCE==null) {
      INSTANCE=new VolleyManager(ctxt.getApplicationContext());
    }

    return(INSTANCE);
  }

  private VolleyManager(Context ctxt) {
    queue=Volley.newRequestQueue(ctxt);
    imageLoader=new ImageLoader(queue, new LruBitmapCache(ctxt));
  }

  void enqueue(Request<?> request) {
    queue.add(request);
  }

  void loadImage(String url, ImageView iv,
                 int placeholderDrawable, int errorDrawable) {
    imageLoader.get(url,
      ImageLoader.getImageListener(iv, placeholderDrawable,
        errorDrawable));
  }
}
```

(from HTTP/Volley/app/src/main/java/com/commonsware/android/volley/VolleyManager.java)

`VolleyManager` holds the singleton instance in a `static` field named `INSTANCE`. That is lazy-initialized via the `get()` method to retrieve the instance, as we need a `Context` for a bit of our work.

The `private` constructor creates a new `RequestQueue` via the `static` `newRequestQueue()` helper method on the `Volley` class. If you prefer to have more control (e.g., supply your own response cache), you can also create a `RequestQueue` via a constructor, then call `start()` on the `RequestQueue` to kick off the thread pool.

We will discuss the rest of `VolleyManager`, including the mysterious `ImageLoader` we are creating in the constructor, a bit later in our examination of the sample app.

Requesting JSON

Volley has built-in support for retrieving strings and images from a Web service. If the Web service serves JSON, Volley also has built-in support for parsing that JSON. However, it uses the legacy `org.json` classes from the Android SDK, which work, but are slow and clunky.

Retrofit has built-in support for retrieving a JSON payload from a Web service via an HTTP request, using Gson to parse that payload into your desired POJOs. Alas, Volley does not offer Gson support out of the box.

The author of Volley, Ficus Kirkpatrick, wrote a `GsonRequest` class that handles this and published it via a GitHub gist. This has since been replicated in the Android documentation. Since this more closely matches what we had in Retrofit, the sample project uses this `GsonRequest`:

```
// from https://gist.github.com/ficusk/5474673

package com.commonsware.android.volley;

import com.google.gson.Gson;
import com.google.gson.JsonSyntaxException;

import com.android.volley.AuthFailureError;
import com.android.volley.NetworkResponse;
import com.android.volley.ParseError;
import com.android.volley.Request;
import com.android.volley.Response;
import com.android.volley.Response.ErrorListener;
import com.android.volley.Response.Listener;
import com.android.volley.toolbox.HttpHeaderParser;

import java.io.UnsupportedEncodingException;
import java.util.Map;

/**
 * Volley adapter for JSON requests that will be parsed into Java objects by Gson.
 */
public class GsonRequest<T> extends Request<T> {
  private final Gson gson = new Gson();
  private final Class<T> clazz;
  private final Map<String, String> headers;
  private final Listener<T> listener;

  /**
   * Make a GET request and return a parsed object from JSON.
   *
   * @param url URL of the request to make
```

```
   * @param clazz Relevant class object, for Gson's reflection
   * @param headers Map of request headers
   */
  public GsonRequest(String url, Class<T> clazz, Map<String, String> headers,
                     Listener<T> listener, ErrorListener errorListener) {
    super(Method.GET, url, errorListener);
    this.clazz = clazz;
    this.headers = headers;
    this.listener = listener;
  }

  @Override
  public Map<String, String> getHeaders() throws AuthFailureError {
    return headers != null ? headers : super.getHeaders();
  }

  @Override
  protected void deliverResponse(T response) {
    listener.onResponse(response);
  }

  @Override
  protected Response<T> parseNetworkResponse(NetworkResponse response) {
    try {
      String json = new String(
        response.data, HttpHeaderParser.parseCharset(response.headers));
      return Response.success(
        gson.fromJson(json, clazz), HttpHeaderParser.parseCacheHeaders(response));
    } catch (UnsupportedEncodingException e) {
      return Response.error(new ParseError(e));
    } catch (JsonSyntaxException e) {
      return Response.error(new ParseError(e));
    }
  }
}
```

(from HTTP/Volley/app/src/main/java/com/commonsware/android/volley/GsonRequest.java)

A custom `Request` implementation like this needs four things:

1. To supply the HTTP method, URL, and a `Response.ErrorListener` to the superclass constructor
2. To override `getHeaders()`, returning a `Map` of HTTP headers to inject into the request, or `null` if there are none
3. To override `parseNetworkResponse()`, taking the raw data from the server and turning into a `Response` wrapped around the actual data to be returned to the app (in this case, the custom POJO parsed by Gson)
4. To override `deliverResponse()`, which may be just a matter of calling `onResponse()` on a `Response.Listener`

However, many developers can get away with using just one of the built-in `Request` implementations, or perhaps other pre-built implementations, like this `GsonRequest`.

Our `QuestionsFragment` can now create a `GsonRequest` for retrieving our Stack Overflow questions and turning them into an `SOQuestions` object. In this version of the sample, the work to populate the `ListView` has been moved from `onCreateView()` to `onViewCreated()`:

```
@Override
public void onViewCreated(View view,
                          Bundle savedInstanceState) {
  super.onViewCreated(view, savedInstanceState);

  GsonRequest<SOQuestions> request=
    new GsonRequest<SOQuestions>(getString(R.string.url),
      SOQuestions.class, null, this, this);

  VolleyManager.get(getActivity()).enqueue(request);
}
```

(from HTTP/Volley/app/src/main/java/com/commonsware/android/volley/QuestionsFragment.java)

The `R.string.url` value points to a string resource containing the full URL, as it is a bit long for a Java code listing, or even to reproduce easily here in this book. However, note two things about it:

1. In the Retrofit-powered examples, we added the `tagged` query parameter via a `@Query` annotated parameter on our `StackOverflowInterface`. That was mostly to demonstrate using such parameters, as we were always requesting the `android` questions. Since we do not have Retrofit's URL construction anymore, the URL in the string resource contains the `tagged=android` query parameter.
2. Because values resource files are XML files, all the `&` characters in the URL need to be escaped as `&`, to satisfy XML parsing rules.

The rest of the `GsonRequest` parameters are the class for the response (`SOQuestions.class`), our extra HTTP headers (`null`), and our implementations of `Listener` and `ErrorListener` (both the fragment itself).

We then retrieve our `VolleyManager` singleton and call `enqueue()` on it, which in turn calls `add()` on the `RequestQueue`, to cause one of Volley's threads to go do the HTTP work and process the result.

`ErrorListener` requires an `onErrorResponse()` method, which works much like its Retrofit counterpart:

```
@Override
public void onErrorResponse(VolleyError error) {
  Toast.makeText(getActivity(), error.getMessage(),
                 Toast.LENGTH_LONG).show();
  Log.e(getClass().getSimpleName(),
        "Exception from Volley request to StackOverflow", error);
}
```

(from HTTP/Volley/app/src/main/java/com/commonsware/android/volley/QuestionsFragment.java)

`Listener` requires an `onResponse()` method, which takes the type of data we are trying to load as a parameter (`SOQuestions`). Once again, this works like its Retrofit counterpart:

```
@Override
public void onResponse(SOQuestions questions) {
  setListAdapter(new ItemsAdapter(questions.items));
}
```

(from HTTP/Volley/app/src/main/java/com/commonsware/android/volley/QuestionsFragment.java)

Requesting Images

Volley has an `ImageRequest`, one that works like `GsonRequest`, except that it gives you a `Bitmap` back. You are welcome to use this, particularly for occasional one-off requests for images.

However, if you are going to be fetching a lot of images — particularly in something like a `ListView`, as the sample app does — you need some more smarts than that. Picasso supplies those smarts to you automatically. With Volley, you use an `ImageLoader`. An `ImageLoader` coordinates loading many images, dealing with things like:

- canceling requests when views get recycled
- having a memory cache for images, to supplement the disk cache that Volley uses for responses
- trying to minimize redraws of the UI when multiple images are decoded roughly simultaneously
- and so on

Now, for reasons that are not entirely clear, while `ImageLoader` needs a memory cache to work properly, it does not have one. Nor does Volley itself. Instead, you have to make your own implementation of `ImageLoader.ImageCache`.

The Android documentation supplies an `LruBitmapCache` that does this, on the back of Android's `LruCache`:

```
// from http://developer.android.com/training/volley/request.html

package com.commonsware.android.volley;

import android.content.Context;
import android.graphics.Bitmap;
import android.support.v4.util.LruCache;
import android.util.DisplayMetrics;
import com.android.volley.toolbox.ImageLoader.ImageCache;

public class LruBitmapCache extends LruCache<String, Bitmap>
  implements ImageCache {

  public LruBitmapCache(int maxSize) {
    super(maxSize);
  }

  public LruBitmapCache(Context ctx) {
    this(getCacheSize(ctx));
  }

  @Override
  protected int sizeOf(String key, Bitmap value) {
    return value.getRowBytes() * value.getHeight();
  }

  @Override
  public Bitmap getBitmap(String url) {
    return get(url);
  }

  @Override
  public void putBitmap(String url, Bitmap bitmap) {
    put(url, bitmap);
  }

  // Returns a cache size equal to approximately three screens worth of images.
  public static int getCacheSize(Context ctx) {
    final DisplayMetrics displayMetrics = ctx.getResources().
      getDisplayMetrics();
    final int screenWidth = displayMetrics.widthPixels;
    final int screenHeight = displayMetrics.heightPixels;
    // 4 bytes per pixel
    final int screenBytes = screenWidth * screenHeight * 4;
```

```
    return screenBytes * 3;
  }
}
```

(from HTTP/Volley/app/src/main/java/com/commonsware/android/volley/LruBitmapCache.java)

The key for any cache, particularly a memory cache, is its maximum size. `LruBitmapCache` lets you specify that directly if you wish. Alternatively, you can provide it with a `Context`, and it will size the cache to be the size of three full-screen images. This is not a great cache sizing algorithm — it is better to tie the size to the maximum heap size of your app — but it is what Google used.

`VolleyManager` creates an `ImageLoader` in its constructor, providing it with an `LruBitmapCache`. `VolleyManager` also has a `loadImage()` method that works a bit like the builder methods on Picasso. It takes four parameters:

- The URL of the image to load
- The `ImageView` into which to load the image
- A drawable resource ID for an image placeholder
- A drawable resource ID for an image to show if there is an error retrieving the real image (e.g., 404 from the Web server when requesting the URL)

`loadImage()` in turn passes those on to the `ImageLoader`, which will handle retrieving the image, caching it, and putting it in the supplied `ImageView`.

The `getView()` method on `ItemsAdapter` can then replace its Picasso code with a call to `loadImage()`:

```
class ItemsAdapter extends ArrayAdapter<Item> {
  ItemsAdapter(List<Item> items) {
    super(getActivity(), R.layout.row, R.id.title, items);
  }

  @Override
  public View getView(int position, View convertView, ViewGroup parent) {
    View row=super.getView(position, convertView, parent);
    Item item=getItem(position);
    ImageView icon=(ImageView)row.findViewById(R.id.icon);

    VolleyManager
      .get(getActivity())
      .loadImage(item.owner.profileImage, icon,
        R.drawable.owner_placeholder,
```

```
          R.drawable.owner_error);

      TextView title=(TextView)row.findViewById(R.id.title);

      title.setText(Html.fromHtml(getItem(position).title));

      return(row);
    }
  }
```

(from HTTP/Volley/app/src/main/java/com/commonsware/android/volley/QuestionsFragment.java)

Comparison with Retrofit + Picasso

Volley's big claim to fame is that it is used in the Play Store app and elsewhere in Google's proprietary apps, supposedly.

However, its lack of official packaging and support makes it a bit more difficult for the average developer to use. It also lacks some of the "creature comforts" of Retrofit and Picasso, requiring a few extra classes to do what Square's libraries provide directly.

Other Candidate Libraries

There are plenty of other libraries that similarly try to help simplify Android HTTP operations, including:

- AndroidAsync
- android-json-rpc
- Universal Image Loader (UIL), which will be used in some samples later in this book

If you happen to be using `support-v4` or `support-v13` from the Android Support package in your app, you might also consider Ion.

The Android Arsenal has categories for general HTTP clients/networking libraries for REST client libraries, and for image loading libraries.

Visit the Trails

As noted earlier, there is a chapter on SSL that you should read, if you run into trouble using SSL in Android or want to improve your security further than you get with just stock SSL handling.

There is also a chapter on miscellaneous network capabilities – the coverage of `DownloadManager` can be found there.

Intents, Intent Filters

We have seen `Intent` objects briefly, in our discussion of having multiple activities in our application. However, we really did not dive into too much of the details about those `Intent` objects, and they can be used in other ways besides starting up an activity. In this chapter, we will examine `Intent` and their filters.

What's Your Intent?

When Sir Tim Berners-Lee cooked up the Hypertext Transfer Protocol — HTTP – he set up a system of verbs plus addresses in the form of URLs. The address indicated a resource, such as a Web page, graphic, or server-side program. The verb indicated what should be done: GET to retrieve it, POST to send form data to it for processing, etc.

An `Intent` is similar, in that it represents an action plus context. There are more actions and more components to the context with `Intent` than there are with HTTP verbs and resources, but the concept is still the same.

Just as a Web browser knows how to process a verb+URL pair, Android knows how to find activities or other application logic that will handle a given `Intent`.

Pieces of Intents

The two most important pieces of an `Intent` are the action and what Android refers to as the "data". These are almost exactly analogous to HTTP verbs and URLs — the action is the verb, and the "data" is a `Uri`, such as `https://commonsware.com` representing an HTTP URL to some balding guy's Web site. Actions are constants, such as `ACTION_VIEW` (to bring up a viewer for the resource) or `ACTION_EDIT` (to edit the resource).

If you were to create an `Intent` combining `ACTION_VIEW` with a content `Uri` of `https://commonsware.com`, and pass that `Intent` to Android via `startActivity()`, Android would know to find and open an activity capable of viewing that resource.

There are other criteria you can place inside an `Intent`, besides the action and "data" `Uri`, such as:

1. Categories. Your "main" activity will be in the `LAUNCHER` category, indicating it should show up on the launcher menu. Other activities will probably be in the `DEFAULT` category, though other categories exist and are used on occasion.
2. A MIME type, indicating the type of resource you want to operate on.
3. A component, which is to say, the class of the activity that is supposed to receive this `Intent`.
4. "Extras", which is a `Bundle` of other information you want to pass along to the receiver with the `Intent`, that the recipient might want to take advantage of. What pieces of information a given recipient can use is up to the recipient and (hopefully) is well-documented.

You will find rosters of the standard actions, categories, and extras in the Android SDK documentation for the `Intent` class.

Intent Routing

As noted above, if you specify the target component in your `Intent`, Android has no doubt where the `Intent` is supposed to be routed to — it will launch the named activity. This might be OK if the target recipient (e.g., the activity to be started) is in your application. It definitely is not recommended for invoking functionality in other applications. Component names, by and large, are considered private to the application and are subject to change. Actions, `Uri` templates, and MIME types are the preferred ways of identifying capabilities you wish third-party code to supply.

If you do not specify the target component, then Android has to figure out what recipients are eligible to receive the `Intent`. For example, Android will take the `Intent` you supply to `startActivity()` and find the activities that might support it. Note the use of the plural "activities", as a broadly-written intent might well resolve to several activities. That is the... ummm... intent (pardon the pun), as you will see later in this chapter. This routing approach is referred to as implicit routing.

Basically, there are three rules, all of which must be true for a given activity to be eligible for a given `Intent`:

- The activity must support the specified action
- The activity must support the stated MIME type (if supplied)
- The activity must support all of the categories named in the `Intent`

The upshot is that you want to make your `Intent` specific enough to find the right recipient, and no more specific than that.

This will become clearer as we work through some examples throughout this chapter.

Stating Your Intent(ions)

All Android components that wish to be started via an `Intent` must declare `Intent` filters, so Android knows which intents should go to that component. A common approach for this is to add one or more `<intent-filter>` elements to your `AndroidManifest.xml` file, inside the element for the component that should respond to the `Intent`.

For example, all of the sample projects in this book have an `<intent-filter>` on an `<activity>` that looks like this:

```
<intent-filter>
  <action android:name="android.intent.action.MAIN"/>
  <category android:name="android.intent.category.LAUNCHER"/>
</intent-filter>
```

Here, we declare that this activity:

1. Is the main activity for this application
2. It is in the `LAUNCHER` category, meaning it gets an icon in anything that thinks of itself as a "launcher", such as the home screen

You are welcome to have more than one action or more than one category in your `Intent` filters. That indicates that the associated component (e.g., activity) handles multiple different sorts of `Intent` patterns.

Responding to Implicit Intents

We saw in the chapter on multiple activities how one activity can start another via an explicit `Intent`, identifying the particular activity to be started:

```
startActivity(new Intent(this, OtherActivity.class));
```

In that case, `OtherActivity` does not need an `<intent-filter>` in the manifest. It will automatically respond when somebody explicitly identifies it as the desired activity.

However, what if you want to respond to an implicit `Intent`, one that focuses on an action string and other values? Then you *will* need an `<intent-filter>` in the manifest.

For example, take a look at the `Intents/FauxSender` sample project.

Here, we have an activity, `FauxSender`, set up to respond to an `ACTION_SEND` `Intent`, specifically for content that has the MIME type of `text/plain`:

```
    <activity
      android:name="FauxSender"
      android:label="@string/app_name"
      android:theme="@android:style/Theme.Translucent.NoTitleBar">
      <intent-filter android:label="@string/app_name">
        <action android:name="android.intent.action.SEND"/>

        <data android:mimeType="text/plain"/>

        <category android:name="android.intent.category.DEFAULT"/>
      </intent-filter>
    </activity>
```

(from Intents/FauxSender/app/src/main/AndroidManifest.xml)

The call to `startActivity()` will always add the `DEFAULT` category if no other category is specified, which is why our `<intent-filter>` also filters on that category.

Hence, if somebody on the system calls `startActivity()` on an `ACTION_SEND` `Intent` with a MIME type of `text/plain`, our `FauxSender` activity might get control. We will explain the use of the term "might" in the next section.

The documentation for `ACTION_SEND` indicates that a standard extra on the `Intent` is `EXTRA_TEXT`, representing the text to be sent. There might also be an `EXTRA_SUBJECT`, representing a subject line, if the "send" operation might have such a concept, such as an email client.

`FauxSender` can retrieve those extras and make use of them:

```
package com.commonsware.android.fsender;

import android.app.Activity;
import android.content.Intent;
import android.os.Bundle;
import android.text.TextUtils;
import android.widget.Toast;

public class FauxSender extends Activity {
  @Override
  public void onCreate(Bundle savedInstanceState) {
    super.onCreate(savedInstanceState);

    String msg=getIntent().getStringExtra(Intent.EXTRA_TEXT);

    if (TextUtils.isEmpty(msg)) {
      msg=getIntent().getStringExtra(Intent.EXTRA_SUBJECT);
    }

    if (TextUtils.isEmpty(msg)) {
      Toast.makeText(this, R.string.no_message_supplied,
                     Toast.LENGTH_LONG).show();
    }
    else {
      Toast.makeText(this, msg, Toast.LENGTH_LONG).show();
    }

    finish();
  }
}
```

(from Intents/FauxSender/app/src/main/java/com/commonsware/android/fsender/FauxSender.java)

Here, we use `TextUtils.isEmpty()` to detect if an extra is either `null` or has an empty string as its value. If `EXTRA_TEXT` is supplied, we show it in a `Toast`. Otherwise, we use `EXTRA_SUBJECT` if it is supplied, and if that is also missing, we show a stock message from a string resource.

The activity then immediately calls `finish()` from `onCreate()` to get rid of itself. That, coupled with `android:theme="@android:style/Theme.Translucent.NoTitleBar"` in the `<activity>` element, means that the activity will have no user interface, beyond the `Toast`. If run from the launcher, you will still see the launcher behind the `Toast`:

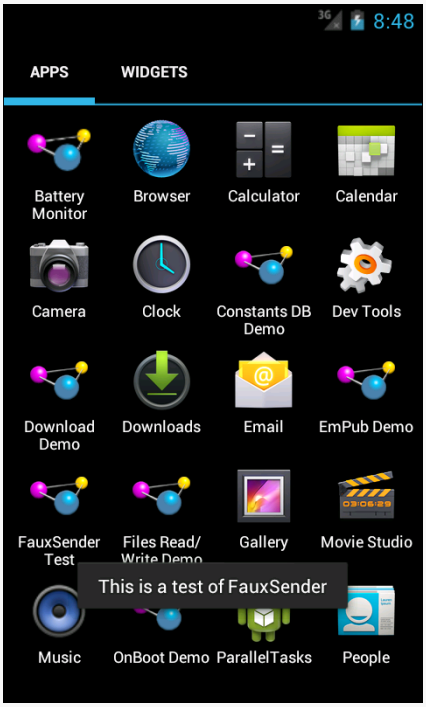

Figure 302: FauxSender, Showing EXTRA_TEXT

Requesting Implicit Intents

To send something via `ACTION_SEND`, you first set up the `Intent`, containing whatever information you want to send in `EXTRA_TEXT`, such as this code from the `FauxSenderTest` activity:

```
    Intent i=new Intent(Intent.ACTION_SEND);

    i.setType("text/plain");
    i.putExtra(Intent.EXTRA_SUBJECT, R.string.share_subject);
    i.putExtra(Intent.EXTRA_TEXT, theMessage);
```

(from Intents/FauxSender/app/src/main/java/com/commonsware/android/fsender/FauxSenderTest.java)

(where `theMessage` is a passed-in parameter to the method containing this code fragment)

If we call `startActivity()` on this `Intent` directly, there are three possible outcomes, described in the following sections.

Zero Matches

It is possible, though unlikely, that there are no activities at all on the device that will be able to handle this `Intent`. In that case, we crash with an `ActivityNotFoundException`. This is a `RuntimeException`, which is why we do not have to keep wrapping all our `startActivity()` calls in `try/catch` blocks. However, if we might start something that does not exist, we really should catch that exception... or avoid the call in the first place. Detecting up front whether there will be any matches for our activity is a topic that will be discussed later in this book.

Note that the odds of an `ActivityNotFoundException` climb substantially on Android 4.3+ tablets, when a restricted profile is in use, as will be discussed later in this book.

One Match

It is possible that there will be exactly one matching activity. In that case, the activity in question starts up and takes over the foreground. This is what we see with the explicit `Intent`.

Many Matches, Default Behavior

It is possible that there will be more than one matching activity. In that case, by default, the user will be presented with a so-called “chooser” dialog box:

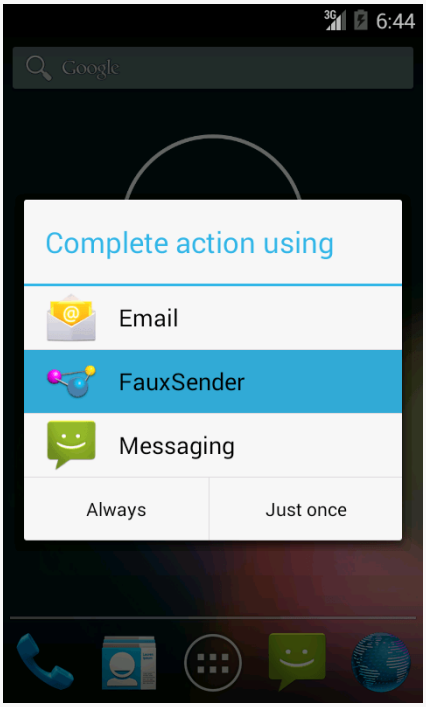

Figure 303: Chooser Dialog

The user can tap on any item in the list to have that particular activity be the one to process this event. And, if the user clicks on "Always", and we invoke the same basic `Intent` again (same action, same MIME type, same categories, same `Uri` scheme), whatever the user chooses *now* will be used again automatically, bypassing the chooser. The "Always" button in the chooser dialog sets the default activity for handling the particular `Intent` structure that triggered the chooser.

The Chooser Override

For many `Intent` patterns, the notion of the user choosing a default makes perfect sense. For example, if the user installs another Web browser, until they set a default activity, every time they go to view a Web page, they will be presented with a chooser, to choose among the installed browsers. This can get annoying quickly.

However, `ACTION_SEND` is one of those cases where a default activity is usually inappropriate. Just because the user on Monday chose to send something via Bluetooth and accidentally clicked "Always" does not mean that every day thereafter, they *always* want *every* `ACTION_SEND` to go via Bluetooth, instead of Gmail or Email or Facebook or Twitter or any other `ACTION_SEND`-capable apps they may have installed.

You can elect to force a chooser to display, regardless of whether the user has set a default activity or not. To do this, instead of calling `startActivity()` on the `Intent` directly, you wrap the `Intent` in another `Intent` returned by the `createChooser()` static method on `Intent` itself:

```
void sendIt(String theMessage) {
  Intent i=new Intent(Intent.ACTION_SEND);

  i.setType("text/plain");
  i.putExtra(Intent.EXTRA_SUBJECT, R.string.share_subject);
  i.putExtra(Intent.EXTRA_TEXT, theMessage);

  startActivity(Intent.createChooser(i,
                                     getString(R.string.share_title)));
}
```

(from Intents/FauxSender/app/src/main/java/com/commonsware/android/fsender/FauxSenderTest.java)

The second parameter to `createChooser()` is a message to appear at the top of the dialog box:

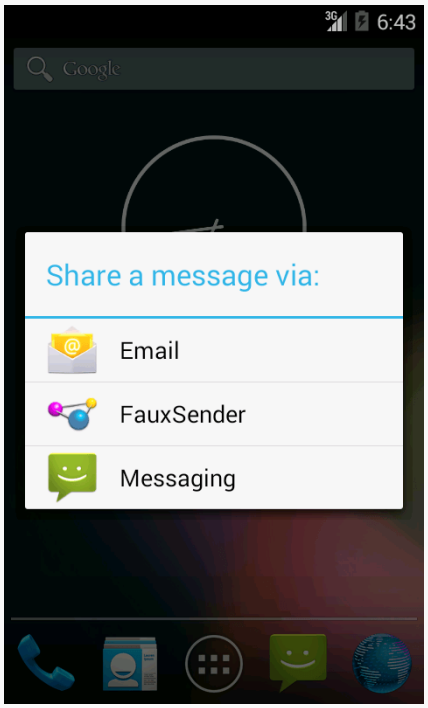

Figure 304: Your Tailored Chooser Dialog

Notice the lack of the "Always" button — not only must the user make a choice now, but also they cannot make a default choice for the future, either.

Direct Share Targets

On Android 6.0, it is possible for an app to not only have an activity appear in the chooser, but also to provide "direct share targets". These items in the chooser are supplied by the app offering an `ACTION_SEND` implementation, but rather than representing a simple activity, they can also have additional data in the extras `Bundle` in the `Intent` used to start that activity. The idea is that the app could offer a few icons to allow sharing to some fine-grained destination, such as a particular contact or a particular folder or something.

Direct share targets are covered later in this book.

ShareActionProvider

Above, we saw how you can bring up a chooser when using `startActivity()` on an implicit `Intent` action, such as `ACTION_SEND`.

There is another option, if you are using the action bar: `ShareActionProvider`. Designed for use with `ACTION_SEND`, `ShareActionProvider` supplies a drop-down menu in the action bar to let the user invoke some implementation of an `Intent` that you configure and supply.

To see how you can add a `ShareActionProvider` to your activity or fragment, let us take a look at the `ActionBar/ShareNative` sample project.

Our activity — `MainActivity` — will utilize the action bar. Its action bar items are contained in a `res/menu/actions.xml` file:

```
<?xml version="1.0" encoding="utf-8"?>
<menu xmlns:android="http://schemas.android.com/apk/res/android">

  <item
    android:id="@+id/share"
    android:actionProviderClass="android.widget.ShareActionProvider"
    android:showAsAction="ifRoom"/>

</menu>
```

(from ActionBar/ShareNative/app/src/main/res/menu/actions.xml)

In addition to specifying an ID and indicating that the item should be shown in the action bar if there is room, we also include the `android:actionProviderClass` attribute. This points to a concrete implementation of the `ActionProvider` abstract base class, which is responsible for rendering the action bar item. In our case, we are using `ShareActionProvider`.

Our activity UI is simply a large `EditText` widget:

```
<EditText xmlns:android="http://schemas.android.com/apk/res/android"
  android:id="@+id/editor"
  android:layout_width="match_parent"
  android:layout_height="match_parent"
  android:gravity="left|top"
  android:inputType="textMultiLine"/>
```

(from ActionBar/ShareNative/app/src/main/res/layout/activity_main.xml)

We load that layout in `onCreate()` of `MainActivity`, along with initializing an `Intent` to be used when we employ the `ShareActionProvider`:

```
package com.commonsware.android.sap;

import android.app.Activity;
import android.content.Intent;
import android.os.Bundle;
import android.text.Editable;
import android.text.TextWatcher;
import android.view.Menu;
import android.widget.EditText;
import android.widget.ShareActionProvider;
import android.widget.Toast;

public class MainActivity extends Activity implements
    ShareActionProvider.OnShareTargetSelectedListener, TextWatcher {
  private ShareActionProvider share=null;
  private Intent shareIntent=new Intent(Intent.ACTION_SEND);
  private EditText editor=null;

  @Override
  public void onCreate(Bundle state) {
    super.onCreate(state);
    setContentView(R.layout.activity_main);

    shareIntent.setType("text/plain");
    editor=(EditText)findViewById(R.id.editor);
    editor.addTextChangedListener(this);
```

```
  }

  @Override
  public boolean onCreateOptionsMenu(Menu menu) {
    getMenuInflater().inflate(R.menu.actions, menu);

    share=
        (ShareActionProvider)menu.findItem(R.id.share)
                                 .getActionProvider();
    share.setOnShareTargetSelectedListener(this);

    return(super.onCreateOptionsMenu(menu));
  }

  @Override
  public boolean onShareTargetSelected(ShareActionProvider source,
                                       Intent intent) {
    Toast.makeText(this, intent.getComponent().toString(),
                   Toast.LENGTH_LONG).show();

    return(false);
  }

  @Override
  public void afterTextChanged(Editable s) {
    shareIntent.putExtra(Intent.EXTRA_TEXT, s.toString());
    share.setShareIntent(shareIntent);
  }

  @Override
  public void beforeTextChanged(CharSequence s, int start, int count,
                                int after) {
    // ignored
  }

  @Override
  public void onTextChanged(CharSequence s, int start, int before,
                            int count) {
    // ignored
  }
}
```

(from ActionBar/ShareNative/app/src/main/java/com/commonsware/android/sap/MainActivity.java)

We also register the activity itself to be a `TextWatcher`, to find out when the user types something into the `EditText` widget.

`onCreateOptionsMenu()` is where we configure the `ShareActionProvider`, which we obtain by calling `findItem()` on our `Menu` to get the item associated with the provider, then calling `getActionProvider()` on the supplied `MenuItem`. Specifically:

- We supply an `Intent` — configured with the action, MIME type, etc. that we wish to invoke — to `setShareIntent()`
- We supply `MainActivity` itself, as an implementation of `OnShareTargetSelectedListener`, via `setOnShareTargetSelectedListener()`

In the `afterTextChanged()` method needed by the `TextWatcher` interface, we update the `EXTRA_TEXT` extra in the `Intent` to be the current contents of the `EditText`. This way, as the user types, we keep the `Intent` "fresh" with respect to what should be shared. Many consumers of a `ShareActionProvider` will have less dynamic contents, in which case you can just set up the `Intent` up front before you register it with the `ShareActionProvider`.

If the user chooses an item from the `ShareActionProvider`, we are notified via a call to our `onShareTargetSelected()` method. Registering as the `OnShareTargetSelectedListener` is optional — Android will automatically start the selected activity without our involvement. `onShareTargetSelected()` is there if you wish to know the means of sharing that the user chose. In our case, we just flash a `Toast` to indicate that the callback worked.

Practice Safe Content Resolution

NOTE: the following is based on a blog post from the author.

Dominik Schürmann and Lars Wolf, in an excellent blog post and pre-pub paper, points out a security flaw in many activities that have an `ACTION_SEND` `<intent-filter>`.

Many `ACTION_SEND` implementations accept `EXTRA_STREAM` as input. That is supposed to point to `Uri` representing a stream of stuff to be sent somewhere. Email apps might send it as an attachment, for example. So, you fire up a `ContentResolver`, call `openInputStream()` to get at the content backed by that `Uri` (because that's how real developers do it), and then do something with that content. You might not even really care what the content *is*... until that content is something from your own app. Like, say, your user account database.

The problem outlined in Mr. Schürmann's post and paper is that a malicious party could provide you with a `file:` `Uri` *to your own internal storage*. While the third-party app cannot access your internal storage, you can. So, in the case of an email app, the attacker asks you to email one of your app's own files to the attacker's email address. The user may be involved in this (e.g., having to actually click something to send the email), but with a bit of phishing or social engineering, that problem can be handled, at least some of the time. After all, courtesy of the `intent:` scheme, some Web browsers and the like will allow a simple link click to trigger the evil `ACTION_SEND` request.

To help with this, cketti (of K-9 Mail fame) wrote a `SafeContentResolver` that has its own `openInputStream()` method. However, this one will fail if the `Uri` points to a file that your app owns or to a `ContentProvider` from your app. If you use this instead of the `openInputStream()` on `ContentResolver`, your `ACTION_SEND` implementation will be safer from this attack.

More generally, if you accept input from outside parties, **validate it**. Have rules for what sorts of `Uri` values you will and will not accept for things like `EXTRA_STREAM`, and provide runtime checks to confirm that the values you receive follow the rules.

Broadcasts and Broadcast Receivers

One channel of the `Intent` message bus is used to start activities. A second channel of the `Intent` message bus is used to send broadcasts. As the name suggests, a broadcast `Intent` is one that — by default – is published to any and all applications on the device that wish to tune in.

Sending a Simple Broadcast

The simplest way to send a broadcast `Intent` is to create the `Intent` you want, then call `sendBroadcast()`.

That's it.

At that point, Android will scan through everything set up to tune into a broadcast matching your `Intent`, typically filtering just on the action string. Anyone set up to receive this broadcast will, indeed, receive it, using a `BroadcastReceiver`.

Receiving a Broadcast: In an Activity

To receive such a broadcast in an activity (or a fragment), you will need to do four things.

First, you will need to create an instance of your own subclass of `BroadcastReceiver`. The only method you need to (or should) implement is `onReceive()`, which will be passed the `Intent` that was broadcast, along with a `Context` object that, in this case, you will typically ignore.

Second, you will need to create an instance of an `IntentFilter` object, describing the sorts of broadcasts you want to receive. Most of these filters are set up to watch for a single broadcast `Intent` action, in which case the simple constructor suffices:

```
new IntentFilter(Intent.ACTION_CAMERA_BUTTON)
```

Third, you will need to call `registerReceiver()`, typically from `onStart()` of your activity or fragment, supplying your `BroadcastReceiver` and your `IntentFilter`.

Fourth, you will need to call `unregisterReceiver()`, typically from `onStop()` of your activity or fragment, supplying the same `BroadcastReceiver` instance you provided to `registerReceiver()`.

In between the calls to `registerReceiver()` and `unregisterReceiver()`, you will receive any broadcasts matching the `IntentFilter`.

The biggest downside to this approach is that some activity has to register the receiver. Sometimes, you want to receive broadcasts even when there is no activity around. To do that, you will need to use a different technique: registering the receiver in the manifest.

Receiving a Broadcast: Via the Manifest

You can also tell Android about broadcasts you wish to receive by adding a `<receiver>` element to your manifest, identifying the class that implements your `BroadcastReceiver` (via the `android:name` attribute), plus an `<intent-filter>` that describes the broadcast(s) you wish to receive:

```
<receiver android:name=".OnBootReceiver">
  <intent-filter>
    <action android:name="android.intent.action.BOOT_COMPLETED"/>
  </intent-filter>
</receiver>
```

The good news is that this `BroadcastReceiver` will be available for broadcasts occurring at any time. There is no assumption that you have an activity already running that called `registerReceiver()`.

The bad news is that the instance of the `BroadcastReceiver` used by Android to process a broadcast will live for only so long as it takes to execute the `onReceive()` method. At that point, the `BroadcastReceiver` is discarded. Hence, it is not safe for a manifest-registered `BroadcastReceiver` to do anything that needs to run after

`onReceive()` itself completes, such as forking a thread. After all, Android may well terminate the process within milliseconds, if there is no other running component in the process.

More bad news: `onReceive()` is called on the main application thread — the same main application thread that handles the UI of all of your activities. And, you are subject to the same limitations as are your activity lifecycle methods and anything else called on the main application thread:

- Any time spent in `onReceive()` will freeze your UI, if you happen to have a foreground activity
- If you spend too long in `onReceive()`, Android will terminate your `BroadcastReceiver` without waiting for `onReceive()` to complete

This makes using a manifest-registered `BroadcastReceiver` a bit tricky. If the work to be done is very quick, just implement it in `onReceive()`. Otherwise, you will probably need to pair this `BroadcastReceiver` with a component known as an `IntentService`, which we will examine in the next chapter.

The Stopped State

On Android 3.1 and higher, when your app is first installed on the device, it is in a "stopped" state. This has nothing to do with `onStop()` of any activity. While in the stopped state, your manifest-registered `BroadcastReceivers` will not receive any broadcasts.

Getting Out of the Stopped State

To get out of the stopped state, something on the device, such as another app (that itself is not in the stopped state), must use an explicit `Intent` to invoke one of your components.

The most common way this happens is for the user to tap on a launcher icon associated with your launcher activity. Under the covers, the home screen's launcher will create an explicit `Intent`, identifying your activity, and use that with `startActivity()`. This moves you out of the stopped state.

Getting Into the Stopped State

As noted above, you start off in the stopped state. Once you are moved out of the stopped state, via the explicit `Intent`, you will remain out of the stopped state until one of two things happens:

1. The user uninstalls your app
2. The user "force-stops" your app

The latter normally occurs when the user clicks the "Force Stop" button on your app's screen in the Settings app (Settings > Apps). There is some evidence that some device manufacturers have tied their own device's task manager to do a "force stop" when the user removes a task — this was not a particularly wise choice on the part of those manufacturers.

Note that a reboot does *not* move you back into the stopped state. You remain in the normal state through a reboot.

Example System Broadcasts

There are many, many broadcasts sent out by Android itself, which you can tune into if you see fit. Many, but not all, of these are documented on the `Intent` class. The values in the "Constants" table that have "Broadcast Action" leading off their description are action strings used for system broadcasts. There are other such broadcast actions scattered around the SDK, though, so do not assume that they are all documented on `Intent`.

The following sections will examine two of these broadcasts, to see how the `BroadcastReceiver` works in action.

At Boot Time

A popular request is to have code get control when the device is powered on. This is doable but somewhat dangerous, in that too many on-boot requests slow down the device startup and may make things sluggish for the user.

In order to be notified when the device has completed its system boot process, you will need to request the `RECEIVE_BOOT_COMPLETED` permission. Without this, even if you arrange to receive the boot broadcast `Intent`, it will not be dispatched to your receiver.

As the Android documentation describes it:

> Though holding this permission does not have any security implications, it can have a negative impact on the user experience by increasing the amount of time it takes the system to start and allowing applications to have themselves running without the user being aware of them. As such, you must explicitly declare your use of this facility to make that visible to the user.

We also need to register our `BroadcastReceiver` in the manifest — by the time an activity would call `registerReceiver()`, the boot will have long since occurred.

For example, let us examine the `Intents/OnBoot` sample project.

In our manifest, we request the needed permission and register our `BroadcastReceiver`, along with an activity:

```
<?xml version="1.0" encoding="utf-8"?>
<manifest xmlns:android="http://schemas.android.com/apk/res/android"
  package="com.commonsware.android.sysevents.boot"
  android:versionCode="1"
  android:versionName="1.0">

  <uses-sdk
    android:minSdkVersion="7"
    android:targetSdkVersion="11"/>

  <supports-screens
    android:largeScreens="false"
    android:normalScreens="true"
    android:smallScreens="false"/>

  <uses-permission android:name="android.permission.RECEIVE_BOOT_COMPLETED"/>

  <application
    android:icon="@drawable/ic_launcher"
    android:label="@string/app_name">
    <receiver android:name=".OnBootReceiver">
      <intent-filter>
        <action android:name="android.intent.action.BOOT_COMPLETED"/>
      </intent-filter>
    </receiver>

    <activity
      android:name="BootstrapActivity"
```

```
      android:theme="@android:style/Theme.Translucent.NoTitleBar">
      <intent-filter>
        <action android:name="android.intent.action.MAIN"/>

        <category android:name="android.intent.category.LAUNCHER"/>
      </intent-filter>
    </activity>
  </application>

</manifest>
```

(from Intents/OnBoot/app/src/main/AndroidManifest.xml)

`OnBootReceiver` simply logs a message to Logcat:

```
package com.commonsware.android.sysevents.boot;

import android.content.BroadcastReceiver;
import android.content.Context;
import android.content.Intent;
import android.util.Log;

public class OnBootReceiver extends BroadcastReceiver {
  @Override
  public void onReceive(Context context, Intent intent) {
    Log.d(getClass().getSimpleName(), "Hi, Mom!");
  }
}
```

(from Intents/OnBoot/app/src/main/java/com/commonsware/android/sysevents/boot/OnBootReceiver.java)

To test this on Android 3.0 and earlier, simply install the application and reboot the device — you will see the message appear in Logcat.

However, on Android 3.1 and higher, the user must first manually launch some activity before any manifest-registered `BroadcastReceiver` objects will be used, as noted above in the section covering the stopped state. Hence, if you were to just install the application and reboot the device, nothing would happen. The little `BootstrapActivity` is merely there for the user to launch, so that the `ACTION_BOOT_COMPLETED` `BroadcastReceiver` will start working.

On Battery State Changes

One theme with system events is to use them to help make your users happier by reducing your impacts on the device while the device is not in a great state. Most

applications are impacted by battery life. Dead batteries run no apps. Hence, knowing the battery level may be important for your app.

There is an `ACTION_BATTERY_CHANGED` `Intent` that gets broadcast as the battery status changes, both in terms of charge (e.g., 80% charged) and charging (e.g., the device is now plugged into AC power). You simply need to register to receive this `Intent` when it is broadcast, then take appropriate steps.

One of the limitations of `ACTION_BATTERY_CHANGED` is that you have to use `registerReceiver()` to set up a `BroadcastReceiver` to get this `Intent` when broadcast. You cannot use a manifest-declared receiver. There are separate `ACTION_BATTERY_LOW` and `ACTION_BATTERY_OK` broadcasts that you *can* receive from a manifest-registered receiver, but they are broadcast far less frequently, only when the battery level falls below or rises above some undocumented "low" threshold.

To demonstrate `ACTION_BATTERY_CHANGED`, take a peek at the `Intents/OnBattery` sample project.

In there, you will find a `res/layout/batt.xml` resource containing a `ProgressBar`, a `TextView`, and an `ImageView`, to serve as a battery monitor:

```
<?xml version="1.0" encoding="utf-8"?>
<LinearLayout xmlns:android="http://schemas.android.com/apk/res/android"
  android:layout_width="match_parent"
  android:layout_height="match_parent"
  android:orientation="vertical">

  <ProgressBar
    android:id="@+id/bar"
    style="?android:attr/progressBarStyleHorizontal"
    android:layout_width="match_parent"
    android:layout_height="wrap_content"/>

  <LinearLayout
    android:layout_width="match_parent"
    android:layout_height="wrap_content"
    android:orientation="horizontal">

    <TextView
      android:id="@+id/level"
      android:layout_width="0px"
      android:layout_height="wrap_content"
      android:layout_weight="1"
      android:textSize="36sp"/>
```

```
    <ImageView
      android:id="@+id/status"
      android:layout_width="0px"
      android:layout_height="wrap_content"
      android:layout_weight="1"/>
  </LinearLayout>

</LinearLayout>
```

(from Intents/OnBattery/app/src/main/res/layout/batt.xml)

This layout is used by a `BatteryFragment`, which registers to receive the `ACTION_BATTERY_CHANGED` `Intent` in `onStart()` and unregisters in `onStop()`:

```
package com.commonsware.android.battmon;

import android.app.Fragment;
import android.content.BroadcastReceiver;
import android.content.Context;
import android.content.Intent;
import android.content.IntentFilter;
import android.os.BatteryManager;
import android.os.Bundle;
import android.view.LayoutInflater;
import android.view.View;
import android.view.ViewGroup;
import android.widget.ImageView;
import android.widget.ProgressBar;
import android.widget.TextView;

public class BatteryFragment extends Fragment {
  private ProgressBar bar=null;
  private ImageView status=null;
  private TextView level=null;

  @Override
  public View onCreateView(LayoutInflater inflater, ViewGroup parent,
                           Bundle savedInstanceState) {
    View result=inflater.inflate(R.layout.batt, parent, false);

    bar=(ProgressBar)result.findViewById(R.id.bar);
    status=(ImageView)result.findViewById(R.id.status);
    level=(TextView)result.findViewById(R.id.level);

    return(result);
  }
```

```
@Override
public void onStart() {
  super.onStart();

  IntentFilter f=new IntentFilter(Intent.ACTION_BATTERY_CHANGED);

  getActivity().registerReceiver(onBattery, f);
}

@Override
public void onStop() {
  getActivity().unregisterReceiver(onBattery);

  super.onStop();
}

BroadcastReceiver onBattery=new BroadcastReceiver() {
  public void onReceive(Context context, Intent intent) {
    int pct=
        100 * intent.getIntExtra(BatteryManager.EXTRA_LEVEL, 1)
            / intent.getIntExtra(BatteryManager.EXTRA_SCALE, 1);

    bar.setProgress(pct);
    level.setText(String.valueOf(pct));

    switch (intent.getIntExtra(BatteryManager.EXTRA_STATUS, -1)) {
      case BatteryManager.BATTERY_STATUS_CHARGING:
        status.setImageResource(R.drawable.charging);
        break;

      case BatteryManager.BATTERY_STATUS_FULL:
        int plugged=
            intent.getIntExtra(BatteryManager.EXTRA_PLUGGED, -1);

        if (plugged == BatteryManager.BATTERY_PLUGGED_AC
            || plugged == BatteryManager.BATTERY_PLUGGED_USB) {
          status.setImageResource(R.drawable.full);
        }
        else {
          status.setImageResource(R.drawable.unplugged);
        }
        break;

      default:
        status.setImageResource(R.drawable.unplugged);
        break;
    }
  }
```

```
  };
}
```

(from Intents/OnBattery/app/src/main/java/com/commonsware/android/battmon/BatteryFragment.java)

The key to `ACTION_BATTERY_CHANGED` is in the "extras". Many extras are packaged in the `Intent`, to describe the current state of the battery, such as the following constants defined on the `BatteryManager` class:

- `EXTRA_HEALTH`, which should generally be `BATTERY_HEALTH_GOOD`
- `EXTRA_LEVEL`, which is the proportion of battery life remaining as an integer, specified on the scale described by the `EXTRA_SCALE` value
- `EXTRA_PLUGGED`, which will indicate if the device is plugged into AC power (`BATTERY_PLUGGED_AC`) or USB power (`BATTERY_PLUGGED_USB`)
- `EXTRA_SCALE`, which indicates the maximum possible value of level (e.g., 100, indicating that level is a percentage of charge remaining)
- `EXTRA_STATUS`, which will tell you if the battery is charging (`BATTERY_STATUS_CHARGING`), full (`BATTERY_STATUS_FULL`), or discharging (`BATTERY_STATUS_DISCHARGING`)
- `EXTRA_TECHNOLOGY`, which indicates what sort of battery is installed (e.g., `"Li-Ion"`)
- `EXTRA_TEMPERATURE`, which tells you how warm the battery is, in tenths of a degree Celsius (e.g., 213 is 21.3 degrees Celsius)
- `EXTRA_VOLTAGE`, indicating the current voltage being delivered by the battery, in millivolts

In the case of `BatteryFragment`, when we receive an `ACTION_BATTERY_CHANGED` `Intent`, we do three things:

1. We compute the percentage of battery life remaining, by dividing the level by the scale
2. We update the `ProgressBar` and `TextView` to display the battery life as a percentage
3. We display an icon, with the icon selection depending on whether we are charging (status is `BATTERY_STATUS_CHARGING`), full but on the charger (status is `BATTERY_STATUS_FULL` and plugged is `BATTERY_PLUGGED_AC` or `BATTERY_PLUGGED_USB`), or are not plugged in

If you plug this into a device, it will show you the device's charge level:

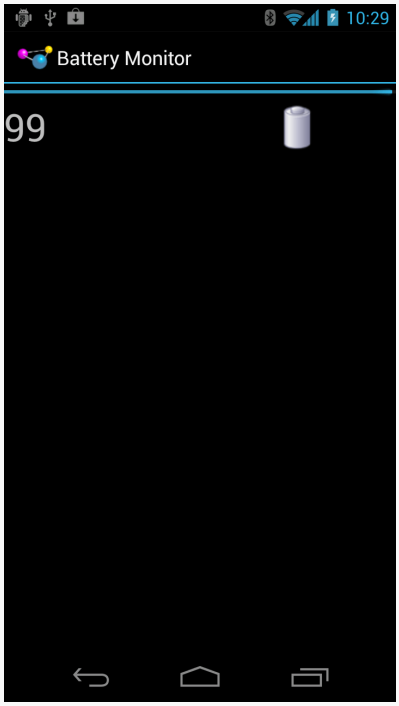

Figure 305: The Battery Monitor

Sticky Broadcasts and the Battery

NOTE: Sticky broadcasts are deprecated in Android 5.0, and the documentation hints that they may be abandoned entirely in the future.

Android has a notion of "sticky broadcast `Intents`". Normally, a broadcast `Intent` will be delivered to interested parties and then discarded. A sticky broadcast `Intent` is delivered to interested parties and retained until the next matching `Intent` is broadcast. Applications can call `registerReceiver()` with an `IntentFilter` that matches the sticky broadcast, but with a `null` `BroadcastReceiver`, and get the sticky `Intent` back as a result of the `registerReceiver()` call.

This may sound confusing. Let's look at this in the context of the battery.

Earlier in this section, you saw how to register for `ACTION_BATTERY_CHANGED` to get information about the battery delivered to you. You can also, though, get the latest battery information without registering a receiver. Just create an `IntentFilter` to match `ACTION_BATTERY_CHANGED` (as shown above) and call `registerReceiver()` with that filter and a `null` `BroadcastReceiver`. The `Intent` you get back from `registerReceiver()` is the last `ACTION_BATTERY_CHANGED` `Intent` that was broadcast,

with the same extras. Hence, you can use this to get the current (or near-current) battery status, rather than having to bother registering an actual `BroadcastReceiver`.

This is why the sample app shows its results immediately — it was given the last-broadcast edition of the `ACTION_BATTERY_CHANGED` broadcast once we called `registerReceiver()`.

Battery and the Emulator

Your emulator does not really have a battery. If you run this sample application on an emulator, you will see, by default, that your device has 50% fake charge remaining and that it is being charged. However, it is charged infinitely slowly, as it will not climb past 50%... at least, not without help.

NOTE: At the time of this writing, the Linux emulator does not properly emulate the battery for AVDs created from certain device profiles (e.g., Nexus S), showing 0% battery charge and not responding to the `telnet` commands described below. If you encounter this, go into the `config.ini` file for your AVD (found in `~/.android/avd/.../`, where `~/` is your home directory and `...` is the name of the AVD) and add `hw.battery=yes` as a property. If that property exists but is set to `no`, change it to `yes`.

While the emulator will only show fixed battery characteristics, you can change what those values are, through the highly advanced user interface known as `telnet`.

You may have noticed that your emulator title bar consists of the name of your AVD plus a number, frequently 5554. That number is not merely some engineer's favorite number. It is also an open port, on your emulator, to which you can `telnet` into, on `localhost` (127.0.0.1) on your development machine.

There are many commands you can issue to the emulator by means of `telnet` . To change the battery level, use `power capacity NN`, where `NN` is the percentage of battery life remaining that you wish the emulator to return. If you do that while you have an `ACTION_BATTERY_CHANGED` `BroadcastReceiver` registered, the receiver will receive a broadcast `Intent`, informing you of the change.

You can also experiment with some of the other power subcommands (e.g., `power ac on` or `power ac off`), or other commands (e.g., `geo`, to send simulated GPS fixes, just as you can do from DDMS).

Battery Data on Android 5.0+

As noted earlier, Android 5.0 deprecates sticky broadcasts. The existing broadcasts still work, though. And, even if someday Android gets rid of sticky broadcasts entirely, broadcasts like `ACTION_BATTERY_CHANGED` most likely will *still* work, albeit just as a regular broadcast.

To get current battery information on Android 5.0 and higher, `BatteryManager` offers `getIntProperty()` and `getLongProperty()`, where the keys for the "properties" are `BATTERY_PROPERTY_*` constants defined on `BatteryManager`, such as `BATTERY_PROPERTY_CAPACITY` to determine the percentage of remaining battery capacity.

The Order of Things

Another variation on the broadcast `Intent` is the ordered broadcast.

Normally, if you broadcast an `Intent`, and there are 10 registered `BroadcastReceivers` that match that `Intent`, all 10 will receive the broadcast, in indeterminate order, and possibly in parallel (particularly on multi-core devices).

With an ordered broadcast, the behavior shifts a bit:

- Only one `BroadcastReceiver` at a time will receive the broadcast
- The order in which the `BroadcastReceivers` receive the broadcast is (somewhat) controlled by their developers
- A `BroadcastReceiver` can "abort" the broadcast, preventing other receivers in the chain from receiving it

Sending an ordered broadcast is merely a matter of calling `sendOrderedBroadcast()`.

Receiving an ordered broadcast, at its core, is identical to receiving a regular broadcast: you write a `BroadcastReceiver` and register it via the manifest or `registerReceiver()`. However, you have two additional options when registering that `BroadcastReceiver`.

First, you can specify a priority, either via `setPriority()` on the `IntentFilter` or `android:priority` on the `<intent-filter>` element. The priority is an integer, with higher numbers indicating higher priority. Higher-priority receivers will get the

broadcast sooner than will lower-priority receivers. The default priority is `0`. In theory, the priority should be a value between `-1000` and `1000`, but this does not seem to be checked by the system, and many apps use a priority higher than `1000`.

Second, your `BroadcastReceiver` can call `abortBroadcast()` to consume the event, preventing any lower-priority receivers from even seeing the broadcast.

Keeping It Local

A broadcast `Intent`, by default and nearly by definition, is broadcast. Anything on the device could have a receiver "tuned in" to listen for such broadcasts. While you can use `setPackage()` on `Intent` to restrict the distribution, the broadcast still goes through the standard broadcast mechanism, which involves transferring the `Intent` to an OS process, which then does the actual broadcasting. Hence, a broadcast `Intent` has some overhead.

Yet, there are times when using broadcasts within an app is handy, but it would be nice to avoid the overhead. To help with this the core Android team added `LocalBroadcastManager` to the Android Support package, to provide an in-process way of doing broadcasts with the standard `Intent`, `IntentFilter`, and `BroadcastReceiver` classes, yet with less overhead.

`LocalBroadcastManager` is supplied by both the `android-support-v4.jar` and `android-support-v13.jar` libraries. Generally speaking, if your `android:minSdkVersion` is less than 13, you probably should choose `android-support-v4.jar`.

The only real difference, from a coding standpoint, in using `LocalBroadcastManager` is that you call `registerReceiver()`, `unregisterReceiver()`, and `sendBroadcast()` on an instance of `LocalBroadcastManager`, instead of on an instance of `Context`. You get the `LocalBroadcastManager` singleton for your process via a static `getInstance()` method on `LocalBroadcastManager` itself.

We will see `LocalBroadcastManager` in use in one of the samples in the services chapter.

Visit the Trails!

We examine `LocalBroadcastManager` in more detail, along with other event bus alternatives, later in the book.

Tutorial #15 - Sharing Your Notes

Perhaps you would like to get your notes off of our book reader app and into someplace else, or perhaps you would like to share them with somebody else. Either way, we can do that using an `ACTION_SEND` operation, to allow the user to choose how to "send" the notes, such as sending them by email or uploading them to some third-party note service.

To make this work, we will add a `ShareActionProvider` to our action bar on the `NoteFragment`.

This is a continuation of the work we did in the previous tutorial.

You can find the results of the previous tutorial and the results of this tutorial in the book's GitHub repository.

Step #1: Adding a ShareActionProvider

First, we need to allow the user to indicate that they want to "share" the note displayed in the current `NoteFragment`. By putting an action bar item on the activity where the `NoteFragment` is displayed, we do not need to worry about letting the user choose which note to send — we simply send whichever note they happen to be viewing or editing.

By using a `ShareActionProvider`, the action item will handle most of the work for allowing the user to choose where to send the note to. We only need to provide an `Intent` that identifies what is to be shared.

Modify `res/menu/notes.xml` to add in the new `share` toolbar button:

```
<?xml version="1.0" encoding="utf-8"?>
<menu xmlns:android="http://schemas.android.com/apk/res/android">
  <item
    android:id="@+id/share"
    android:actionProviderClass="android.widget.ShareActionProvider"
    android:showAsAction="ifRoom"
    android:title="@string/share"/>
  <item
    android:id="@+id/delete"
    android:icon="@drawable/ic_delete_white_24dp"
    android:showAsAction="ifRoom|withText"
    android:title="@string/delete">
  </item>
</menu>
```

(from EmPubLite-AndroidStudio/T15-Share/EmPubLite/app/src/main/res/menu/notes.xml)

Note that this menu definition requires a new string resource, named `share`, with a value like `Share`.

Step #2: Sharing the Note

Now, we need to configure the `ShareActionProvider`, in particular supplying it with a continuously-updated `Intent`, based upon what the user has typed into the `EditText`.

Add a `ShareActionProvider` data member to `NoteFragment`, named `share`, along with an `Intent` data member named `shareIntent` configured to use `ACTION_SEND` of a MIME type of `text/plain`:

```
  private ShareActionProvider share=null;
  private Intent shareIntent=
    new Intent(Intent.ACTION_SEND).setType("text/plain");
```

(from EmPubLite-AndroidStudio/T15-Share/EmPubLite/app/src/main/java/com/commonsware/empublite/NoteFragment.java)

Then, in `onCreateView()`, tell the `EditText` to let us know when the user changes the text, via `addTextChangedListener()`:

```
  @Override
  public View onCreateView(LayoutInflater inflater,
                           ViewGroup container,
                           Bundle savedInstanceState) {
    View result=inflater.inflate(R.layout.editor, container, false);
```

```
    editor=(EditText)result.findViewById(R.id.editor);
    editor.addTextChangedListener(this);

    return(result);
  }
```

(from EmPubLite-AndroidStudio/T15-Share/EmPubLite/app/src/main/java/com/commonsware/empublite/NoteFragment.java)

This will fail to compile, as our `NoteFragment` is not implementing the `TextWatcher` interface. So, modify the `NoteFragment` class declaration to include the `TextWatcher` interface:

```
public class NoteFragment extends Fragment implements TextWatcher {
```

(from EmPubLite-AndroidStudio/T15-Share/EmPubLite/app/src/main/java/com/commonsware/empublite/NoteFragment.java)

That, in turn, will require us to implement three methods:

1. `afterTextChanged()`
2. `beforeTextChanged()`
3. `onTextChanged()`

In our case, we care about `afterTextChanged()`. So, add the following three methods to `NoteFragment`:

```
  @Override
  public void afterTextChanged(Editable s) {
    shareIntent.putExtra(Intent.EXTRA_TEXT, s.toString());
  }

  @Override
  public void beforeTextChanged(CharSequence s, int start, int count,
                                int after) {
    // ignored
  }

  @Override
  public void onTextChanged(CharSequence s, int start, int before,
                            int count) {
    // ignored
  }
```

(from EmPubLite-AndroidStudio/T15-Share/EmPubLite/app/src/main/java/com/commonsware/empublite/NoteFragment.java)

Here, we update the `shareIntent` with the latest text to be shared, storing it in `EXTRA_TEXT`, per the instructions in the Android developer documentation for working with `ACTION_SEND`.

However, we have not initialized `share` yet. We can do that in `onCreateOptionsMenu()`, adding a call to `findItem()` to find our `R.id.share` menu item, then calling `getActionProvider()` to get the `ShareActionProvider` out of the menu item:

```
@Override
public void onCreateOptionsMenu(Menu menu, MenuInflater inflater) {
  inflater.inflate(R.menu.notes, menu);

  share=
    (ShareActionProvider)menu.findItem(R.id.share)
      .getActionProvider();
  share.setShareIntent(shareIntent);

  super.onCreateOptionsMenu(menu, inflater);
}
```

(from EmPubLite-AndroidStudio/T15-Share/EmPubLite/app/src/main/java/com/commonsware/empublite/NoteFragment.java)

Here, we also attach the `shareIntent` to the `ShareActionProvider`, so when it comes time to share the text, the `ShareActionProvider` knows how to do that.

Step #3: Testing the Result

If you run this on a device and navigate to a filled-in note, you will see the new action bar item:

Figure 306: ShareActionProvider in NoteFragment

If you tap on it, you will get a roster of possible ways to share the text:

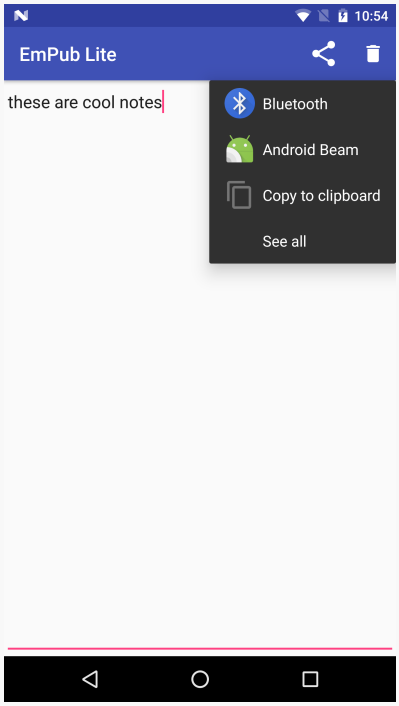

Figure 307: ShareActionProvider in NoteFragment, Expanded

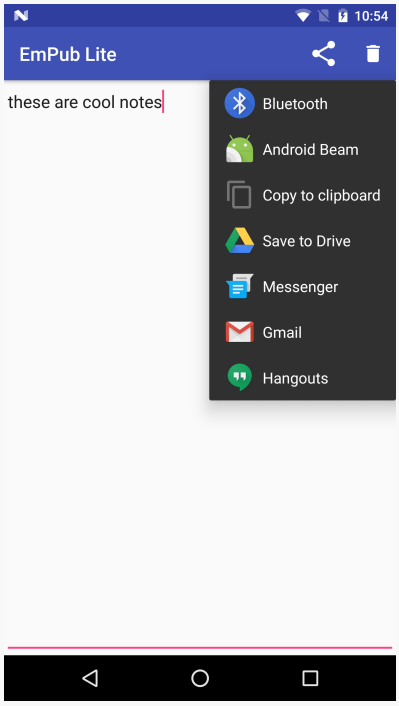

Figure 308: ShareActionProvider in NoteFragment, Fully Expanded

The exact options you see will vary based on your device or emulator, and what apps are installed on it that know how to share plain text. If you only have one choice (e.g., Messenger), it will appear next to the share icon, and you will only be able to tap on that one choice.

Unfortunately, your emulator may have nothing that can handle this `Intent`. If that is the case, you will crash with an `ActivityNotFoundException`. To get past this, if you enter `http://goo.gl/w113e` in your emulator's browser, that should allow you to download and install a copy of the APK from the `Intents/FauxSender` sample project that we covered earlier in this book. When the download is complete (which should be very quick), open up the notification drawer and tap on the "download complete" notification. This should begin the installation process. Depending on your Android version, you may also need to "allow installation of non-Market apps" — after fixing this, you can use the Downloads app on the emulator to try installing the APK again. Once FauxSender is installed, it will respond to your attempts to share a note.

In Our Next Episode…

… we will allow the user to update the book's contents over the Internet.

Services and the Command Pattern

As noted previously, Android services are for long-running processes that may need to keep running even when decoupled from any activity. Examples include playing music even if the "player" activity is destroyed, polling the Internet for RSS/Atom feed updates, and maintaining an online chat connection even if the chat client loses focus due to an incoming phone call.

Services are created when manually started (via an API call) or when some activity tries connecting to the service via inter-process communication (IPC). Services will live until specifically shut down, until Android is desperate for RAM and terminates the process, or for a short period of time on Android 8.0+. Running for a long time has its costs, though, so services need to be careful not to use too much CPU or keep radios active too much of the time, lest the service cause the device's battery to get used up too quickly.

This chapter outlines the basic theory behind creating and consuming services, including a look at the "command pattern" for services.

Why Services?

Services are a "Swiss Army knife" for a wide range of functions that do not require direct access to an activity's user interface, such as:

1. Performing operations that need to continue even if the user leaves the application's activities, like a long download (as seen with the Play Store) or playing music (as seen with Android music apps)
2. Performing operations that need to exist regardless of activities coming and going, such as maintaining a chat connection in support of a chat application

3. Providing a local API to remote APIs, such as might be provided by a Web service
4. Performing periodic work without user intervention, akin to cron jobs or Windows scheduled tasks

Even things like home screen app widgets often involve a service to assist with long-running work.

The primary role of a service is as a flag to the operating system, letting it know that your process is still doing work, despite the fact that it is in the background. This makes it *somewhat* less likely that Android will terminate your process due to low memory conditions.

Many applications will not need any services. Very few applications will need more than one. However, the service is a powerful tool for an Android developer's toolbox and is a subject with which any qualified Android developer should be familiar.

Setting Up a Service

Creating a service implementation shares many characteristics with building an activity. You inherit from an Android-supplied base class, override some lifecycle methods, and hook the service into the system via the manifest.

The Service Class

There are many service classes that you might inherit from.

The root of all of them is `Service`, just as the root of the hierarchy of activity classes is `Activity`. You may wish to subclass `Service`, particularly if:

- You will be using the binding pattern for communicating to that service from another app or process, or
- The service will need to run for an indeterminate period of time, such as a media player that works via user control

Historically, the next-most-common base class was `IntentService`. This was good for a "transactional" bit of work, where you need to have a service do something in the background for a bit, then you no longer need the service. The classic example here is a service to download a large file: once the file is downloaded, you no longer need that service to be around. `IntentService` supplies you with a background

thread to use for the network I/O and disk I/O, and it will shut down automatically once the work is complete.

However, `IntentService` has recently been supplanted by `JobIntentService`. This has similar characteristics, but it works better on Android 8.0+ devices, due to limitations on what you can do in the background.

We will examine all three of these solutions in this chapter.

Beyond those, there are many specialized service classes. Elsewhere in the book you will find examples of:

- `JobService`, for doing periodic or scheduled work
- `TileService`, for adding a custom tile to the notification shade of the device
- `ChooserTargetService`, for helping provide more specific integration options with other apps

And there are plenty of others. While they are all services, and they will all be added to the manifest in the same fashion (more or less), the API that you implement will be very specific to the service that you are extending. The API for `TileService` looks little like the API for `JobService`, for example. As such, those services, where we use them, are covered elsewhere in the book.

Lifecycle Methods

Just as activities have `onCreate()`, `onResume()`, `onPause()` and kin, `Service` implementations have their own lifecycle methods, such as:

- `onCreate()`, which, as with activities, is called when the service is created, by any means
- `onStartCommand()`, which is called each time the service is sent a command via `startService()`
- `onBind()`, which is called whenever a client binds to the service via `bindService()`
- `onDestroy()` which is called as the service is being shut down

As with activities, services initialize whatever they need in `onCreate()` and clean up those items in `onDestroy()`. And, as with activities, the `onDestroy()` method of a service might not be called, if Android terminates the entire application process, such as for emergency RAM reclamation.

The `onStartCommand()` and `onBind()` lifecycle methods will be implemented based on your choice of communicating to the client, as will be explained later in this chapter.

Note that `Service` is an `abstract` class and `onBind()` is an `abstract` method, so even if you are not using `bindService()`, you will need to implement `onBind()` in order to successfully compile. A common approach here is to have `onBind()` simply return `null`.

Note that these methods may be optional, depending upon your needs and the base class that you extend. So, for example, overriding any of these in a `JobIntentService` is unusual at best and a bad idea at worst.

Manifest Entry

Finally, you need to add the service to your `AndroidManifest.xml` file, for it to be recognized as an available service for use. That is simply a matter of adding a `<service>` element as a child of the `application` element, providing `android:name` to reference your service class.

Since the service class is in the same Java namespace as everything else in this application, we can use the shorthand (e.g., `"PlayerService"`) to reference our class.

For example, here is a manifest showing the `<service>` element:

```
<?xml version="1.0" encoding="utf-8"?>
<manifest xmlns:android="http://schemas.android.com/apk/res/android"
  package="com.commonsware.android.fakeplayer"
  android:versionCode="1"
  android:versionName="1.0">

  <supports-screens
    android:anyDensity="true"
    android:largeScreens="true"
    android:normalScreens="true"
    android:smallScreens="true"/>

  <uses-sdk
    android:minSdkVersion="14"
    android:targetSdkVersion="14"/>

  <application
    android:icon="@drawable/ic_launcher"
    android:label="@string/app_name"
```

```
    android:theme="@android:style/Theme.Holo.Light.DarkActionBar">
    <activity
      android:name="FakePlayer"
      android:label="@string/app_name">
      <intent-filter>
        <action android:name="android.intent.action.MAIN"/>

        <category android:name="android.intent.category.LAUNCHER"/>
      </intent-filter>
    </activity>

    <service android:name="PlayerService"/>
  </application>

</manifest>
```

(from Service/FakePlayer/app/src/main/AndroidManifest.xml)

Communicating To Services

Clients of services — frequently activities, though not necessarily — have two main ways to send requests or information to a service. One approach is to send a command, which creates no lasting connection to the service. The other approach is to bind to the service, establishing a communications channel that lasts as long as the client needs it.

Sending Commands with startService()

The simplest way to work with a service is to call `startService()`. The `startService()` method takes an `Intent` parameter, much like `startActivity()` does. In fact, the `Intent` supplied to `startService()` has the same two-part role as it does with `startActivity()`:

1. Identify the service to communicate with
2. Supply parameters, in the form of `Intent` extras, to tell the service what it is supposed to do

For a local service — the focus of this chapter — the simplest form of `Intent` is one that identifies the class that implements the `Service` (e.g., `new Intent(this, MyService.class);`).

The call to `startService()` is asynchronous, so the client will not block. The service will be created if it is not already running, and it will receive the `Intent` via a call to

the `onStartCommand()` lifecycle method. The service can do whatever it needs to in `onStartCommand()`, but since `onStartCommand()` is called on the main application thread, it should do its work very quickly. Anything that might take more than a handful of milliseconds should be delegated to a background thread.

The `onStartCommand()` method can return one of several values, mostly to indicate to Android what should happen if the service's process should be killed while it is running. The most likely return values are:

1. `START_STICKY`, meaning that the service should be moved back into the started state (as if `onStartCommand()` had been called), but do not re-deliver the `Intent` to `onStartCommand()`
2. `START_REDELIVER_INTENT`, meaning that the service should be restarted via a call to `onStartCommand()`, supplying the same `Intent` as was delivered this time
3. `START_NOT_STICKY`, meaning that the service should remain stopped until explicitly started by application code

By default, calling `startService()` not only sends the command, but tells Android to keep the service running until something tells it to stop. One way to stop a service is to call `stopService()`, supplying the same `Intent` used with `startService()`, or at least one that is equivalent (e.g., identifies the same class). At that point, the service will stop and will be destroyed. Note that `stopService()` does not employ any sort of reference counting, so three calls to `startService()` will result in a single service running, which will be stopped by a call to `stopService()`.

Another possibility for stopping a service is to have the service call `stopSelf()` on itself. You might do this if you use `startService()` to have a service begin running and doing some work on a background thread, then having the service stop itself when that background work is completed.

Note that `JobIntentService` has an API that feels like the command pattern, though it uses a different set of methods, as will be explored later in the chapter.

Binding to Services

Another approach to communicating with a service is to use the binding pattern. Here, instead of packaging commands to be sent via an `Intent`, you can obtain an actual API from the service, with whatever data types, return values, and so on that you wish. You then invoke that API no different than you would on some local object.

The benefit is the richer API. The cost is that binding is more complex to set up and more complex to maintain, particularly across configuration changes.

We will discuss the binding pattern later in this book.

Scenario: The Music Player

Most audio player applications in Android — for music, audiobooks, or whatever — do not require the user to remain in the player application itself. Rather, the user can go on and do other things with their device, with the audio playing in the background.

The sample project reviewed in this section is `Service/FakePlayer`.

The Design

We will use `startService()`, since we want the service to run even when the activity starting it has been destroyed. However, we will use a regular `Service`, rather than an `IntentService` or `JobIntentService`. Those are designed to do work and stop itself, whereas in this case, we want the user to be able to stop the music playback when the user wants to.

Since music playback is outside the scope of this chapter, the service will simply stub out those particular operations.

The Service Implementation

Here is the implementation of this `Service`, named `PlayerService`:

```
package com.commonsware.android.fakeplayer;

import android.app.Service;
import android.content.Intent;
import android.os.IBinder;
import android.util.Log;

public class PlayerService extends Service {
  public static final String EXTRA_PLAYLIST="EXTRA_PLAYLIST";
  public static final String EXTRA_SHUFFLE="EXTRA_SHUFFLE";
  private boolean isPlaying=false;

  @Override
```

```
  public int onStartCommand(Intent intent, int flags, int startId) {
    String playlist=intent.getStringExtra(EXTRA_PLAYLIST);
    boolean useShuffle=intent.getBooleanExtra(EXTRA_SHUFFLE, false);

    play(playlist, useShuffle);

    return(START_NOT_STICKY);
  }

  @Override
  public void onDestroy() {
    stop();
  }

  @Override
  public IBinder onBind(Intent intent) {
    return(null);
  }

  private void play(String playlist, boolean useShuffle) {
    if (!isPlaying) {
      Log.w(getClass().getName(), "Got to play()!");
      isPlaying=true;
    }
  }

  private void stop() {
    if (isPlaying) {
      Log.w(getClass().getName(), "Got to stop()!");
      isPlaying=false;
    }
  }
}
```

(from Service/FakePlayer/app/src/main/java/com/commonsware/android/fakeplayer/PlayerService.java)

In this case, we really do not need anything for `onCreate()`, so that lifecycle method is skipped. On the other hand, we have to implement `onBind()`, because that is an abstract method on `Service`.

When the client calls `startService()`, `onStartCommand()` is called in `PlayerService`. Here, we get the `Intent` and pick out some extras to tell us what to play back (`EXTRA_PLAYLIST`) and other configuration details (e.g., `EXTRA_SHUFFLE`). `onStartCommand()` calls `play()`, which simply flags that we are playing and logs a message to Logcat — a real music player would use `MediaPlayer` to start playing the first song in the playlist. `onStartCommand()` returns `START_NOT_STICKY`, indicating

that if Android terminates the process (e.g., low memory), it should not restart it once conditions improve.

`onDestroy()` stops the music from playing — theoretically, anyway — by calling a `stop()` method. Once again, this just logs a message to Logcat, plus updates our internal are-we-playing flag.

Using the Service

The `PlayerFragment` demonstrating the use of `PlayerService` has a very elaborate UI, consisting of two large buttons:

```
<?xml version="1.0" encoding="utf-8"?>
<LinearLayout xmlns:android="http://schemas.android.com/apk/res/android"
  android:layout_width="match_parent"
  android:layout_height="match_parent"
  android:orientation="vertical">

  <Button
    android:id="@+id/start"
    android:layout_width="match_parent"
    android:layout_height="match_parent"
    android:layout_weight="1"
    android:text="@string/start_the_player"/>

  <Button
    android:id="@+id/stop"
    android:layout_width="match_parent"
    android:layout_height="match_parent"
    android:layout_weight="1"
    android:text="@string/stop_the_player"/>

</LinearLayout>
```

(from Service/FakePlayer/app/src/main/res/layout/main.xml)

The fragment itself is not much more complex:

```
package com.commonsware.android.fakeplayer;

import android.content.Intent;
import android.os.Bundle;
import android.support.v4.app.Fragment;
import android.view.LayoutInflater;
import android.view.View;
import android.view.ViewGroup;
```

```
public class PlayerFragment extends Fragment implements
    View.OnClickListener {
  @Override
  public View onCreateView(LayoutInflater inflater, ViewGroup parent,
                           Bundle savedInstanceState) {
    View result=inflater.inflate(R.layout.main, parent, false);

    result.findViewById(R.id.start).setOnClickListener(this);
    result.findViewById(R.id.stop).setOnClickListener(this);

    return(result);
  }

  @Override
  public void onClick(View v) {
    Intent i=new Intent(getActivity(), PlayerService.class);

    if (v.getId() == R.id.start) {
      i.putExtra(PlayerService.EXTRA_PLAYLIST, "main");
      i.putExtra(PlayerService.EXTRA_SHUFFLE, true);

      getActivity().startService(i);
    }
    else {
      getActivity().stopService(i);
    }
  }
}
```

(from Service/FakePlayer/app/src/main/java/com/commonsware/android/fakeplayer/PlayerFragment.java)

The `onCreateView()` method merely loads the UI. The `onClick()` method constructs an `Intent` with fake values for `EXTRA_PLAYLIST` and `EXTRA_SHUFFLE`, then calls `startService()`. After you press the "Start" button, you will see the corresponding message in Logcat. Similarly, `stopPlayer()` calls `stopService()`, triggering the second Logcat message. Notably, you do not need to keep the activity running in between those button clicks — you can exit the activity via BACK and come back later to stop the service.

Communicating *From* Services

Sending commands to a service, by default, is a one-way street. Frequently, though, we need to get results from our service back to our activity. There are a few approaches for how to accomplish this.

Broadcast Intents

One approach, first mentioned in the chapter on Intent filters, is to have the service send a broadcast Intent that can be picked up by the activity... assuming the activity is still around and is not paused. The service can call sendBroadcast(), supplying an Intent that identifies the broadcast, designed to be picked up by a BroadcastReceiver. This could be a component-specific broadcast (e.g., new Intent(this, MyReceiver.class)), if the BroadcastReceiver is registered in the manifest. Or, it can be based on some action string, perhaps one even documented and designed for third-party applications to listen for.

The activity, in turn, can register a BroadcastReceiver via registerReceiver(), though this approach will only work for Intent objects specifying some action, not ones identifying a particular component. But, when the activity's BroadcastReceiver receives the broadcast, it can do what it wants to inform the user or otherwise update itself.

However, for local services, this is not a good choice. System broadcasts like this are intrinsically system-wide; for a local service, you should be using a communications channel that is private to your process.

Pending Results

Your activity can call createPendingResult(). This returns a PendingIntent – an object that represents an Intent and the corresponding action to be performed upon that Intent (e.g., use it to start an activity). In this case, the PendingIntent will cause a result to be delivered to your activity's implementation of onActivityResult(), just as if another activity had been called with startActivityForResult() and, in turn, called setResult() to send back a result.

Since a PendingIntent is Parcelable, and can therefore be put into an Intent extra, your activity can pass this PendingIntent to the service. The service, in turn, can call one of several flavors of the send() method on the PendingIntent, to notify the activity (via onActivityResult()) of an event, possibly even supplying data (in the form of an Intent) representing that event.

We will be seeing PendingIntent used many places later in this book, such as with notifications and AlarmManager.

Event Buses

Event bus implementations — like `LocalBroadcastManager` or greenrobot's EventBus — are a great solution for having a service communicate with objects elsewhere within your process. You can have the service raise events (e.g., `NewEmailEvent`, `UploadCompletedEvent`, `MartiansHaveLandedEvent`), which activities or fragments can listen for and respond to.

Messenger

Yet another possibility is to use a `Messenger` object. A `Messenger` sends messages to an activity's `Handler`. Within a single activity, a `Handler` can be used to send messages to itself, as was mentioned briefly in the chapter on threads. However, between components — such as between an activity and a service — you will need a `Messenger` to serve as the bridge.

As with a `PendingIntent`, a `Messenger` is `Parcelable`, and so can be put into an `Intent` extra. The activity calling `startService()` or `bindService()` would attach a `Messenger` as an extra on the `Intent`. The service would obtain that `Messenger` from the `Intent`. When it is time to alert the activity of some event, the service would:

1. Call `Message.obtain()` to get an empty `Message` object
2. Populate that `Message` object as needed, with whatever data the service wishes to pass to the activity
3. Call `send()` on the `Messenger`, supplying the `Message` as a parameter

The `Handler` will then receive the message via `handleMessage()`, on the main application thread, and so can update the UI or whatever is necessary.

Notifications

Another approach is for the service to let the user know directly about the work that was completed. To do that, a service can raise a `Notification` — putting an icon in the status bar and optionally shaking or beeping or something. This technique is covered in an upcoming chapter.

We can also combine these techniques, such as using an event bus event and detecting when nothing in the UI layer receives the event, so we know that we need to display a `Notification`. We will be examining this pattern later in the book as well.

Scenario: The Downloader

If you elect to download something from the Play Store, you are welcome to back out of the Play Store application entirely. This does not cancel the download – the download and installation run to completion, despite no Play Store activity being on-screen.

You may have similar circumstances in your application, from downloading a purchased e-book to downloading a map for a game to downloading a file from some sort of "drop box" file-sharing service. And, perhaps `DownloadManager` is not going to be a great choice, for any number of reasons (e.g., you want to download the file to internal storage).

The sample project reviewed in this section is `Service/Downloader`, which implements such a downloading service.

The Design

This sort of situation is a perfect use for the command pattern and either an `IntentService` or a `JobIntentService`. Either of those have a background thread, so downloads can take as long as needed. Either of those will automatically shut down when the work is done, so the service will not linger and you do not need to worry about shutting it down yourself. Your activity can simply send a command to tell it to go do the work.

In this sample, we will use an `IntentService`. A clone of this project that uses a `JobIntentService` appears later in this chapter.

Admittedly, things get a bit trickier when you want to have the activity find out when the download is complete. This example will show the use of `LocalBroadcastManager` for this.

Things get even trickier when you want to download to a public location on external storage, such as the `Downloads` directory. On Android 6.0+ devices, with a `targetSdkVersion` of 23 or higher, you need to request runtime permissions before you can write to external storage. However, requesting runtime permissions needs to be done by the UI layer — a service cannot request permissions on its own (though it can check to see if the app has permission). The simplest thing to do is to request the permissions, if needed, before starting the service. This sample app demonstrates this.

Using the Service

The `DownloadFragment` demonstrating the use of `Downloader` has a trivial UI, consisting of one large button:

```
<?xml version="1.0" encoding="utf-8"?>
<Button xmlns:android="http://schemas.android.com/apk/res/android"
  android:id="@+id/button"
  android:layout_width="match_parent"
  android:layout_height="match_parent"
  android:text="@string/do_the_download"
/>
```

(from Service/Downloader/app/src/main/res/layout/main.xml)

That UI is initialized in `onCreateView()`, as usual:

```
  @Override
  public View onCreateView(LayoutInflater inflater, ViewGroup parent,
                           Bundle savedInstanceState) {
    View result=inflater.inflate(R.layout.main, parent, false);

    b=result.findViewById(R.id.button);
    b.setOnClickListener(this);

    return(result);
  }
```

(from Service/Downloader/app/src/main/java/com/commonsware/android/downloader/DownloadFragment.java)

When the user clicks the button, `onClick()` is called. What happens now depends on whether we have permission to write to external storage or not:

```
  @Override
  public void onClick(View v) {
    if (hasPermission(WRITE_EXTERNAL_STORAGE)) {
      doTheDownload();
    }
    else {
      requestPermissions(
        new String[] { WRITE_EXTERNAL_STORAGE }, REQUEST_STORAGE);
    }
  }
```

(from Service/Downloader/app/src/main/java/com/commonsware/android/downloader/DownloadFragment.java)

The first time the user runs the app, the app will not have permission yet. `hasPermission(WRITE_EXTERNAL_STORAGE)` will return `false`, where `hasPermission()` is a utility method wrapping around `ContextCompat.checkSelfPermission()`:

```
  private boolean hasPermission(String perm) {
    return(ContextCompat.checkSelfPermission(getActivity(), perm)==
      PackageManager.PERMISSION_GRANTED);
  }
```

(from Service/Downloader/app/src/main/java/com/commonsware/android/downloader/DownloadFragment.java)

`WRITE_EXTERNAL_STORAGE` is a `static` import, just to cut down on verbosity:

```
import static android.Manifest.permission.WRITE_EXTERNAL_STORAGE;
```

(from Service/Downloader/app/src/main/java/com/commonsware/android/downloader/DownloadFragment.java)

If `hasPermission()` returns `false`, we call `requestPermissions()` on `FragmentCompat`, as we are in a fragment, not an activity. That eventually routes to `onRequestPermissionsResult()`:

```
  @Override
  public void onRequestPermissionsResult(int requestCode, String[] permissions,
                                         int[] grantResults) {
    if (hasPermission(WRITE_EXTERNAL_STORAGE)) {
      doTheDownload();
    }
  }
```

(from Service/Downloader/app/src/main/java/com/commonsware/android/downloader/DownloadFragment.java)

Hence, if we either have permission when the user clicks the button, or if we receive permission after asking for it, we call a `doTheDownload()` method to kick off the download. Specifically, we disable the button (to prevent accidental duplicate downloads) and call `startService()` to send over a command:

```
  private void doTheDownload() {
    b.setEnabled(false);

    Intent i=new Intent(getActivity(), Downloader.class);

    i.setData(Uri.parse("https://commonsware.com/Android/Android-1_0-CC.pdf"));

    getActivity().startService(i);
  }
```

(from Service/Downloader/app/src/main/java/com/commonsware/android/downloader/DownloadFragment.java)

Here, the `Intent` we pass over has the URL of the file to download (in this case, a URL pointing to a PDF).

The Service Implementation

Here is the implementation of this `IntentService`, named `Downloader`:

```
package com.commonsware.android.downloader;

import android.app.IntentService;
import android.content.Intent;
import android.os.Environment;
import android.support.v4.content.LocalBroadcastManager;
import android.util.Log;
import java.io.BufferedOutputStream;
import java.io.File;
import java.io.FileOutputStream;
import java.io.IOException;
import java.io.InputStream;
import java.net.HttpURLConnection;
import java.net.URL;

public class Downloader extends IntentService {
  public static final String ACTION_COMPLETE=
      "com.commonsware.android.downloader.action.COMPLETE";

  public Downloader() {
    super("Downloader");
  }

  @Override
  public void onHandleIntent(Intent i) {
    try {
      File root=
          Environment.getExternalStoragePublicDirectory(Environment.DIRECTORY_DOWNLOADS);

      root.mkdirs();

      File output=new File(root, i.getData().getLastPathSegment());

      if (output.exists()) {
        output.delete();
      }

      URL url=new URL(i.getData().toString());
      HttpURLConnection c=(HttpURLConnection)url.openConnection();

      FileOutputStream fos=new FileOutputStream(output.getPath());
      BufferedOutputStream out=new BufferedOutputStream(fos);

      try {
        InputStream in=c.getInputStream();
        byte[] buffer=new byte[8192];
        int len=0;
```

```
        while ((len=in.read(buffer)) >= 0) {
          out.write(buffer, 0, len);
        }

        out.flush();
      }
      finally {
        fos.getFD().sync();
        out.close();
        c.disconnect();
      }

      LocalBroadcastManager.getInstance(this)
                           .sendBroadcast(new Intent(ACTION_COMPLETE));
    }
    catch (IOException e2) {
      Log.e(getClass().getName(), "Exception in download", e2);
    }
  }
}
```

(from Service/Downloader/app/src/main/java/com/commonsware/android/downloader/Downloader.java)

Our business logic is in `onHandleIntent()`, which is called on an Android-supplied background thread, so we can take whatever time we need. Also, when `onHandleIntent()` ends, the `IntentService` will stop itself automatically... assuming no other requests for downloads occurred while `onHandleIntent()` was running. In that case, `onHandleIntent()` is called again for the next download, and so on.

In `onHandleIntent()`, we first set up a `File` object pointing to where we want to download the file. We use `getExternalStoragePublicDirectory()` to find the public folder for downloads. Since this directory may not exist, we need to create it using `mkdirs()`. We then use the `getLastPathSegment()` convenience method on `Uri`, which returns to us the filename portion of a path-style `Uri`. The result is that our `output` `File` object points to a file, named the same as the file we are downloading, in a public folder.

We then go through a typical `HttpUrlConnection` process to connect to the URL supplied via the `Uri` in the `Intent`, streaming the results from the connection (8KB at a time) out to our designated file. Then, we follow the requested recipe to ensure our file is saved:

- `flush()` the stream
- `sync()` the `FileDescriptor` (from `getFD()`)
- `close()` the stream

This recipe was explained back in the chapter on file I/O.

Finally, it would be nice to let somebody know that the download has completed. So, we send a local broadcast `Intent`, with our own custom action (`ACTION_COMPLETE`), using `LocalBroadcastManager`.

Note that, in theory, we could start the service, but the user could revoke our permission before we get a chance to start the download. In practice, this is very unlikely to happen, as our download should start within milliseconds. However, when working with runtime permissions from services, you need to consider the length of time between confirming that you have permission and when you perform the actions secured by that permission. If there may be a significant time gap, double-check the permission before trying the actions (e.g., writing to external storage). It is cleaner to recover from `checkSelfPermission()` indicating that you do not have permission than from some `IOException` or `SecurityException` because you do not have permission and tried the action anyway.

If your service determines that it does *not* have permission, you cannot call `requestPermissions()`, as a service is neither an activity nor a fragment. Instead, raise a notification and gracefully exit the service. The notification can direct the user somewhere in the app where you can request the permission (again) and re-try the work to be done by the service.

Receiving the Broadcast

Our `DownloadFragment` is set up to listen for that local broadcast `Intent`, by registering a local `BroadcastReceiver` in `onStart()` and unregistering it in `onStop()`:

```
@Override
public void onStart() {
  super.onStart();

  IntentFilter f=new IntentFilter(Downloader.ACTION_COMPLETE);

  LocalBroadcastManager.getInstance(getActivity())
                       .registerReceiver(onEvent, f);
}

@Override
public void onStop() {
  LocalBroadcastManager.getInstance(getActivity())
                       .unregisterReceiver(onEvent);
```

```
    super.onStop();
  }
```

(from Service/Downloader/app/src/main/java/com/commonsware/android/downloader/DownloadFragment.java)

The `BroadcastReceiver` itself re-enables our button, plus displays a `Toast` indicating that the download is complete:

```
  private BroadcastReceiver onEvent=new BroadcastReceiver() {
    public void onReceive(Context ctxt, Intent i) {
      b.setEnabled(true);

      Toast.makeText(getActivity(), R.string.download_complete,
                     Toast.LENGTH_LONG).show();
    }
  };
```

(from Service/Downloader/app/src/main/java/com/commonsware/android/downloader/DownloadFragment.java)

Note that if the user leaves the activity (e.g., BACK, HOME), the broadcast will not be received by the activity. There are other ways of addressing this, particularly combining an ordered broadcast with a `Notification`, which we will examine later in this book.

Limitation: Time

On Android 7.1 and older, this sample app works fine.

On Android 8.0 and newer, this sample app works fine... because the PDF file that it is trying to download is not that big.

However, on Android 8.0+, a started service like this can run for only one minute. After that, Android will stop the service. That will not terminate our background thread immediately, but it will make it far more likely that Android will terminate our entire process, taking our thread and download with it.

As a result, nowadays, an `IntentService` is suitable only for scenarios where you are quite certain that the work will get done in less than a minute.

One way to work around this is to make the service be a "foreground service". In the upcoming chapter on notifications, we will revisit this sample and discuss the use of `startForeground()` to make a service be a foreground service.

Another workaround is to use `JobIntentService`, as we will see in the next section.

Limitation: Staying Awake

Even if our work is certain to take less than a minute, we may run into another problem: the device might fall asleep. When the screen turns off, by default, Android will power down the CPU, suspending all running processes. This, in turn, will prevent us from downloading the file anymore.

`JobIntentService` works around this by way of a "wakelock": a request to the OS to keep the device awake, even though the screen turns off. You can use a wakelock yourself to keep the device awake, for scenarios where you need that capability but where `JobIntentService` is not a great option. We will explore wakelocks in greater detail in the chapter on `AlarmManager`.

JobIntentService

`IntentService` still works on Android 8.0, but unless you make it be a foreground service, you will be limited to ~1 minute of runtime before your service is stopped abruptly. `JobIntentService` is a wrapper around a `JobService` that offers `IntentService`-style semantics. On Android 8.0 and higher, when you tell a `JobIntentService` to do some work, it enqueues that work via `JobScheduler`. On Android 7.1 and earlier, the `JobIntentService` behaves more like a regular `IntentService`, though one that supplies a `WakeLock` for you (akin to the author's `WakefulIntentService`).

The `Service/JobIntentService` sample project is a clone of the `IntentService` sample, where we use the service to download a PDF file. The revised sample swaps out the `IntentService` with a `JobIntentService`, which is a fairly easy conversion to make.

First, we need to defend it with the `android.permission.BIND_JOB_SERVICE` permission:

```
    <service
      android:name="Downloader"
      android:permission="android.permission.BIND_JOB_SERVICE" />
```

(from Service/JobIntentService/app/src/main/AndroidManifest.xml)

This is required because, under the covers, a `JobIntentService` is really a `JobService`, and `JobService` requires this `android:permission` attribute. We will explore this more in the chapter on `JobScheduler`.

What had been `onHandleIntent()` in an `IntentService` turns into `onHandleWork()` in a `JobIntentService`:

```
package com.commonsware.android.downloader;

import android.content.Context;
import android.content.Intent;
import android.os.Environment;
import android.support.v4.app.JobIntentService;
import android.support.v4.content.LocalBroadcastManager;
import android.util.Log;
import java.io.BufferedOutputStream;
import java.io.File;
import java.io.FileOutputStream;
import java.io.IOException;
import java.io.InputStream;
import java.net.HttpURLConnection;
import java.net.URL;

public class Downloader extends JobIntentService {
  public static final String ACTION_COMPLETE=
      "com.commonsware.android.downloader.action.COMPLETE";
  private static final int UNIQUE_JOB_ID=1337;

  static void enqueueWork(Context ctxt, Intent i) {
    enqueueWork(ctxt, Downloader.class, UNIQUE_JOB_ID, i);
  }

  @Override
  public void onHandleWork(Intent i) {
    try {
      File root=
          Environment.getExternalStoragePublicDirectory(Environment.DIRECTORY_DOWNLOADS);

      root.mkdirs();

      File output=new File(root, i.getData().getLastPathSegment());

      if (output.exists()) {
        output.delete();
      }

      URL url=new URL(i.getData().toString());
      HttpURLConnection c=(HttpURLConnection)url.openConnection();

      FileOutputStream fos=new FileOutputStream(output.getPath());
      BufferedOutputStream out=new BufferedOutputStream(fos);

      try {
        InputStream in=c.getInputStream();
        byte[] buffer=new byte[8192];
        int len=0;

        while ((len=in.read(buffer)) >= 0) {
          out.write(buffer, 0, len);
        }

        out.flush();
```

```
      }
      finally {
        fos.getFD().sync();
        out.close();
        c.disconnect();
      }

      LocalBroadcastManager.getInstance(this)
                           .sendBroadcast(new Intent(ACTION_COMPLETE));
    }
    catch (IOException e2) {
      Log.e(getClass().getName(), "Exception in download", e2);
    }
  }
}
```

(from Service/JobIntentService/app/src/main/java/com/commonsware/android/downloader/Downloader.java)

The semantics of `onHandleWork()` are the same as `doWakefulWork()` with a `WakefulIntentService`:

- The method is called on a background thread
- While there is work to be done, a wakelock is held
- Once there is no more work to be done and the method returns, the service stops itself

Because our code is using a wakelock — by way of a support library — we need to have the `WAKE_LOCK` permission in the manifest, along with other permissions needed for our business logic:

```
  <uses-permission android:name="android.permission.WAKE_LOCK" />
  <uses-permission android:name="android.permission.INTERNET" />
  <uses-permission android:name="android.permission.WRITE_EXTERNAL_STORAGE" />
```

(from Service/JobIntentService/app/src/main/AndroidManifest.xml)

To arrange to have the service perform some work, with `IntentService`, you would use `startService()`, with an `Intent` identifying the service (and, optionally, passing along details of the work to be done). With `JobIntentService`, you instead call a static `enqueueWork()` method defined on `JobIntentService`. This takes four parameters:

- a `Context`
- the Java `Class` object for your `JobIntentService` subclass (e.g., `Downloader.class`)

- a job ID, which will be used on Android 8.0 when using `JobScheduler` to perform the work, where the job ID needs to be unique within your app compared to anything else that is using `JobScheduler`
- an `Intent` akin to the one you would have used with `startService()` and `IntentService`

Since the second and third parameters are constants, you can create your own `enqueueWork()` method that calls the `JobService` implementation, passing along those constant values:

```
private static final int UNIQUE_JOB_ID=1337;

static void enqueueWork(Context ctxt, Intent i) {
  enqueueWork(ctxt, Downloader.class, UNIQUE_JOB_ID, i);
}
```

(from Service/JobIntentService/app/src/main/java/com/commonsware/android/downloader/Downloader.java)

Then, your code that wishes to have the work performed calls your `enqueueWork()` method to do so:

```
private void doTheDownload() {
  b.setEnabled(false);

  Intent i=new Intent(getActivity(), Downloader.class);

  i.setData(Uri.parse("https://commonsware.com/Android/Android-1_0-CC.pdf"));

  Downloader.enqueueWork(getActivity(), i);
}
```

(from Service/JobIntentService/app/src/main/java/com/commonsware/android/downloader/DownloadFragment.java)

The `JobIntentService` can spend up to ~10 minutes in `onHandleWork()` on Android 8.0+, which is a substantial improvement over the ~1 minute a background `IntentService` has. If, however, there is a substantial chance that the work would exceed 10 minutes, use a foreground `IntentService`.

However, there is one issue with `JobIntentService`: on Android 8.0+, it may not do its work right away. On Android 8.0+, `JobIntentService` schedules its work via `JobScheduler`, and `JobScheduler` may elect to postpone that work for a bit. In cases where you really need the work to be started immediately, `JobIntentService` is not a good choice.

IntentService or JobIntentService?

Use `JobIntentService` if:

- You can live with the possible slight delay in the work being started, and
- You think that the work might take more than a minute, but surely less than 10 minutes

Use a plain `IntentService` if you are sure that the work will take less than a minute.

Use a foreground `IntentService` if either:

- You think that the work might take more than a minute, but you want to avoid the possible delayed-start of a `JobIntentService`, or
- You think that the work might take more than 10 minutes

Services and Configuration Changes

Services are not directly affected by configuration changes the way that activities are. While activities will be destroyed and recreated by default, services continue running if they were created.

Usually, services do not really care about configuration changes. However, if you have a service that *does* care, you can override `onConfigurationChanged()` in the service.

This means that you have two choices for dealing with configuration changes: override `onConfigurationChanged()` or simply re-read in the configuration information as needed. For example, suppose that you need to know the user's chosen locale, to include as information in a Web service call. If you are checking the locale on each Web service call, your service does not need to know about configuration changes. If, on the other hand, you prefer to cache the locale data, reading it in from the `Locale` class when the service is created, you will want to override `onConfigurationChanged()` and update that cache, in case the configuration change was a locale change.

When Do Services End?

One common question with services is: when do services end? If we start them, what causes them to ever stop?

While services are designed to run in the background for a while, they will not run forever. Exactly how long they will run depends on what stops them, and there are several scenarios for that.

Scenario #1: You Stop It

If you call `stopSelf()` from inside a started service, the service is stopped and destroyed. Or, if you call `stopService()` from something outside of the service — but supplying an `Intent` that identifies your service — the service is stopped and destroyed. In both cases, the service is stopped and destroyed asynchronously, so the service will be running for a bit even after the `stopSelf()` or `stopService()` call. However, the service will be stopped and destroyed fairly quickly, assuming that you are not tying up the main application thread for some reason.

As we will see in the chapter on binding and remote services, if you unbind from a bound service, and nothing else has bound to it or has started it, Android will destroy the service.

So, you can cause a service to stop by taking some positive action to stop it, much as we did with the `stopService()` call in the `FakePlayer` example earlier in this chapter.

Scenario #2: Android Terminates Your Process

The real point behind a service is to elevate your process' importance within the operating system. Android terminates low-importance processes to free up system RAM for other processes representing other apps.

However, while process importance is the primary criterion for Android to choose processes to terminate, it is not the only criterion. Process age and memory consumption are also taken into account. As a result, your process will not run forever, even with a service running.

Needless to say, when your process is terminated, your service goes with it.

Scenario #3: The User Nukes You From Orbit

Not only can Android terminate your process, but so can the user, by any number of ways:

- Using a third-party task manager
- Swiping your app off of the recent-tasks ("overview") screen
- Clicking "Force Stop" on your page in the Settings app

In the first two scenarios, if you had a running service, and if your `onStartCommand()` returns something like `START_STICKY` or `START_REDELIVER_INTENT`, eventually Android will fork a fresh process for you and restart your service. This also happens if Android terminates your process on its own due to old age.

If the user presses "Force Stop", nothing of your app will run again, until the user launches your app from the home screen or something else uses an explicit `Intent` to start one of your components.

Scenario #4: Automatically, After a Minute

All of the previous options have been a possibility for a long time, frequently since Android 1.0.

New to Android 8.0 is a time limit on background services: you can run for a minute, and then you're done. We will explore this more in the next section.

Background Service Limitations

For apps that have a `targetSdkVersion` of 26 or higher and are running on Android 8.0, background services are limited. After a short period of time — as low as one minute — any such services will be stopped and you will be unable to start new ones.

Also, even if your `targetSdkVersion` is 25 or lower, you might *still* have these limitations applied to your app. If your app appears on the Battery screen in Settings — indicating that it is using above-average power — the user will have the ability to apply these limitations to your app from there.

What Is a Background Service, Exactly?

Here, "background services" are ones that:

- Have not used something like `startForeground()` to raise themselves to foreground importance (with a `Notification`),
- Are in a process that is not showing the foreground UI at the moment, and
- Are not bound to by some other process that happens to have foreground importance

That latter scenario covers cases where your service exposes an API that is bound to by other apps or by core OS processes. This includes custom APIs implemented via AIDL and framework-supplied APIs such as those used by `JobService`, `TileService`, and so on.

Certain events, such as having your code triggered by a `Notification` `PendingIntent`, or by receiving a broadcast, will also give you a fresh window of time when background services behave normally.

What Happens?

The documentation indicates that when your process moves from the foreground to the background, or when one of the other triggers (e.g., receiving a broadcast) occurs, you have "several minutes" of normal operation. Testing suggests that by "several minutes", Google actually means "a minute or so".

At that point:

- Any outstanding services are stopped and destroyed, via `stopService()`-style functionality, and
- Any calls to `startService()` will fail

Your process is still running at this point. However, its importance is the same as if you had no service running, meaning that your process is at risk of being terminated at any point to free up system RAM.

Note that while the documentation suggests that `startService()` will throw an `IllegalStateException` when your app is ineligible to start a background service, this behavior varies. If a service calls `startService()`, no exception is thrown, and the call seems to fail quietly. If another `Context` is used — such as a `BroadcastReceiver` — you will get the exception:

```

What Are the Alternatives?

An obvious solution is to use a foreground service. You have three options for doing this:

- The classic solution, which is to start the service via `startService()`, then have the service call `startForeground()`
- The new `getForegroundService()` method on `PendingIntent`
- The new `startForegroundService()` method on `Context`

The latter two approaches work even when your process no longer has the ability to call `startService()`. However, those methods are new to Android 8.0. Also, despite their method names, they do not actually start your service as a foreground service. Rather, they give you a short reprieve from the normal service-starting limits — your service needs to call `startForeground()` shortly after being created, or else your service will be destroyed.

A `JobService` can spend ~10 minutes processing a job, before Android will consider the service to be broken and reduce the process' priority to lower levels. Hence, using `JobScheduler` may be an option for you, particularly if the work you are trying to do is periodic in nature, where your `JobService` does the work.

As this change only affects apps with a `targetSdkVersion` higher than 25, keeping your `targetSdkVersion` at 25 or lower will avoid this behavior change.

Tutorial #16 - Updating the Book

The app is designed to ship a copy of the book's chapters as assets, so a user can just download one thing and get everything they need: book and reader.

However, sometimes books get updated. This is a bit less likely with the material being used in this tutorial, as it is rather unlikely that H. G. Wells will rise from the grave to amend *The War of the Worlds*. However, other books, such as Android developer guides written by balding guys, might be updated more frequently.

Most likely, the way you would get those updates is by updating the entire app, so you get improvements to the reader as well. However, another approach would be to be able to download an update to the book as a separate ZIP file. The reader would use the contents of that ZIP file if one has been downloaded, otherwise it will "fall back" to the copy in assets. That is the approach that we will take in this tutorial, to experiment a bit with Internet access and services. Along the way, we will use Retrofit to call a Web service (of sorts) to find out if an update is available.

This is a continuation of the work we did in the previous tutorial.

You can find the results of the previous tutorial and the results of this tutorial in the book's GitHub repository.

Step #1: Adding a Stub DownloadCheckService

There are a few pieces to our download-the-book-update puzzle:

- We need to determine if there is an update available and, if so, where we can find the ZIP file that is the update
- We need to download the update's ZIP file, which could be a fairly large file

- We need to unpack that ZIP file into internal or external storage, so that it is more easily used by the rest of our code and performs more quickly than would dynamically reading the contents out of the ZIP on the fly
- All of that needs to happen in the background from a threading standpoint
- Ideally, all of that could happen either in the foreground or the background from a UI standpoint (i.e., user manually requests an update check, or an update check is performed automatically on a scheduled basis)

To address the first puzzle piece — determining if there is an update available — we can use an `IntentService`. That makes it easy for us to do the work not only in the background from a threading standpoint, but also be able to use it either from the UI or from some sort of background-work scheduler. So, let's add a `DownloadCheckService` to our project.

Right-click over the `com.commonsware.empublite` package in your `java/` directory and choose New > Service > "Service (IntentService)" from the context menu. Fill in `DownloadCheckService` as the class name and uncheck the "helper methods" checkbox. Click Finish to generate the `DownloadCheckService` class and add an entry for you to the manifest.

Then, replace the generated implementation of `DownloadCheckService` with:

```
package com.commonsware.empublite;

import android.app.IntentService;
import android.content.Intent;

public class DownloadCheckService extends IntentService {
  public DownloadCheckService() {
    super("DownloadCheckService");
  }

  @Override
  protected void onHandleIntent(Intent intent) {
  }
}
```

Step #2: Tying the Service Into the Action Bar

To allow the user to manually request that we update the book (if an update is available), we should add a new action bar item to `EmPubLiteActivity`.

Right-click over the `res/` directory and choose New > Vector Asset from the context menu. Click the Icon button and search for the "refresh" icon:

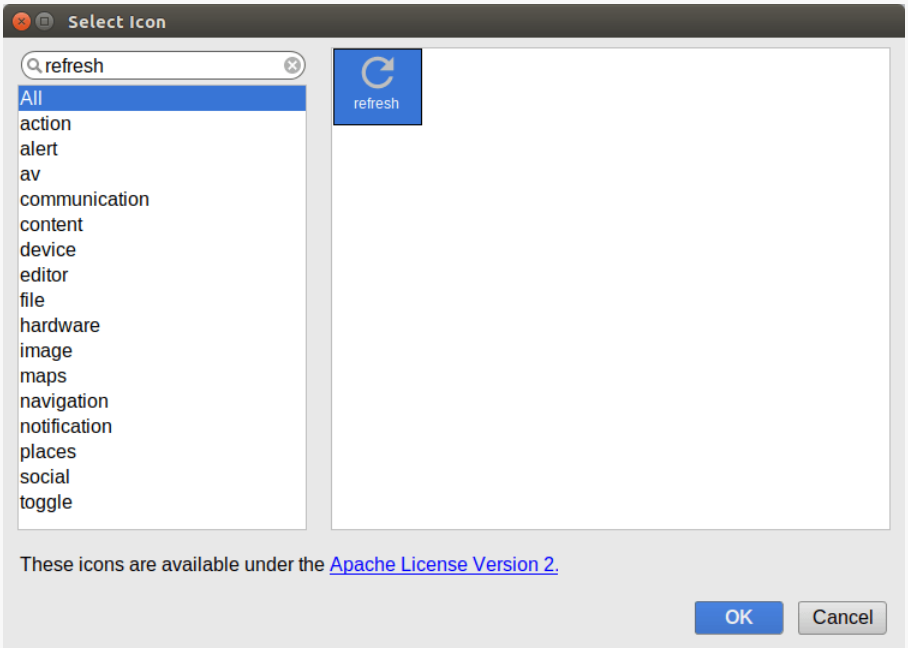

Figure 309: Asset Studio Icon Picker, with Refresh Icon Selected

Click OK to close the icon picker. Change the resource name to `ic_refresh_white_24dp`. Then click Next and Finish to save this drawable resource.

Once again, this icon will render in black, when we need it to render in white given our theme. Open `res/drawable/ic_refresh_white_24dp.xml` and change the `android:fillColor` in the `<path>` element to be `#FFFFFFFF` instead of `#FF000000`:

```
<vector xmlns:android="http://schemas.android.com/apk/res/android"
        android:width="24dp"
        android:height="24dp"
        android:viewportWidth="24.0"
        android:viewportHeight="24.0">
    <path
        android:fillColor="#FFFFFFFF"
        android:pathData="M17.65,6.35C16.2,4.9 14.21,4 12,4c-4.42,0 -7.99,3.58 -7.99,8s3.57,8
7.99,8c3.73,0 6.84,-2.55 7.73,-6h-2.08c-0.82,2.33 -3.04,4 -5.65,4 -3.31,0 -6,-2.69 -6,-6s2.69,-6
6,-6c1.66,0 3.14,0.69 4.22,1.78L13,11h7V4l-2.35,2.35z"/>
</vector>
```

(from EmPubLite-AndroidStudio/T16-Update/EmPubLite/app/src/main/res/drawable/ic_refresh_white_24dp.xml)

Then, modify the `res/menu/options.xml` file to include the following `<item>` element:

```
<item
  android:id="@+id/update"
  android:icon="@drawable/ic_refresh_white_24dp"
  android:showAsAction="ifRoom|withText"
  android:title="@string/download_update">
</item>
```

(from EmPubLite-AndroidStudio/T16-Update/EmPubLite/app/src/main/res/menu/options.xml)

Note that this menu definition requires a new string resource, named `download_update`, with a value like `Download Update`.

That allows us to add a new `case` to the `switch` statement in `onOptionsItemSelected()` in `EmPubLiteActivity`:

```
    case R.id.update:
      startService(new Intent(this, DownloadCheckService.class));

      return(true);
```

(from EmPubLite-AndroidStudio/T16-Update/EmPubLite/app/src/main/java/com/commonsware/empublite/EmPubLiteActivity.java)

All we do here is send a command to our `DownloadCheckService` to see if a download is available.

Step #3: Defining Our Event

Our `IntentService` will do the work of updating the book in the background. However, we will want to let the rest of the app know when the book is updated. In particular, the `ModelFragment`, if it exists, needs to know that there is a new set of book contents to display. To accomplish this, we can use another event on our `EventBus`, a `BookUpdatedEvent` in this case.

Right-click over the `com.commonsware.empublite` package in your `java/` directory and choose New > Java Class from the context menu. Fill in `BookUpdatedEvent` as the name and click OK to create the empty class.

Step #4: Defining Our JSON

Under the covers, Retrofit uses GSON for parsing the JSON it retrieves from the Web service (or other URL). Hence, just as we needed to define a Java class that models

our JSON for the book contents, we need a Java class that models the data we will get from our server as to whether or not a book update is available.

That JSON looks like:

```
{
  "updatedOn": "20120512",
  "updateUrl": "http://misc.commonsware.com/WarOfTheWorlds-Update.zip"
}
```

We can create a `BookUpdateInfo` class that mimics this structure.

Right-click over the `com.commonsware.empublite` package in your `java/` directory and choose New > Java Class from the context menu. Fill in `BookUpdateInfo` as the name and click OK to create the empty class.

Then, with `BookUpdateInfo` open in the editor, paste in the following class definition:

```
package com.commonsware.empublite;

public class BookUpdateInfo {
  String updatedOn;
  String updateUrl;
}
```

(from EmPubLite-AndroidStudio/T16-Update/EmPubLite/app/src/main/java/com/commonsware/empublite/BookUpdateInfo.java)

If you prefer, you can view this file's contents in your Web browser via this GitHub link.

Step #5: Defining Our Retrofit Interface

Retrofit then needs a Java *interface* that provides most of the details for how to fetch our JSON and convert it into a Java object. In our case, we will be using an HTTP `GET` operation to retrieve the JSON, and so we will use the Retrofit `@GET` annotation to point to a path on a server pointing to that JSON.

Right-click over the `com.commonsware.empublite` package in your `java/` directory and choose New > Java Class from the context menu. Fill in `BookUpdateInterface` as the name, switch the "Kind" to be "Interface", and click OK to create the empty interface.

Then, with `BookUpdateInterface` open in the editor, paste in the following interface definition:

```
package com.commonsware.empublite;

import retrofit2.Call;
import retrofit2.http.GET;

public interface BookUpdateInterface {
  @GET("/misc/empublite-update.json")
  Call<BookUpdateInfo> update();
}
```

(from EmPubLite-AndroidStudio/T16-Update/EmPubLite/app/src/main/java/com/commonsware/empublite/BookUpdateInterface.java)

If you prefer, you can view this file's contents in your Web browser via this GitHub link.

Here, we define our interface as having an `update()` method, returning an instance of our `BookUpdateInfo` structure, with the `@GET` annotation pointing to a path where the corresponding JSON can be found on a server to be designated later.

Step #6: Retrieving Our JSON Via Retrofit

Now, we can actually use Retrofit to retrieve our `BookUpdateInfo` and see if we have a book update.

First, we need to add the `INTERNET` permission to our app, as we are going to be downloading materials from the `INTERNET`. Add the following `<uses-permission>` element as a child of the root `<manifest>` element in `AndroidManifest.xml`:

```
  <uses-permission android:name="android.permission.INTERNET" />
```

(from EmPubLite-AndroidStudio/T16-Update/EmPubLite/app/src/main/AndroidManifest.xml)

Next, in `DownloadCheckService`, add an `OUR_BOOK_DATE` static data member, representing the edit date of the book baked into our APK, in YYYYMMDD format:

```
  private static final String OUR_BOOK_DATE="20120418";
```

(from EmPubLite-AndroidStudio/T16-Update/EmPubLite/app/src/main/java/com/commonsware/empublite/DownloadCheckService.java)

Then, add a `getUpdateUrl()` method to `DownloadCheckService`:

```
private String getUpdateUrl() throws IOException {
  Retrofit retrofit=
    new Retrofit.Builder()
      .baseUrl("https://commonsware.com")
      .addConverterFactory(GsonConverterFactory.create())
      .build();
  BookUpdateInterface updateInterface=
    retrofit.create(BookUpdateInterface.class);
  BookUpdateInfo info=updateInterface.update().execute().body();

  if (info.updatedOn.compareTo(OUR_BOOK_DATE) > 0) {
    return(info.updateUrl);
  }

  return(null);
}
```

(from EmPubLite-AndroidStudio/T16-Update/EmPubLite/app/src/main/java/com/commonsware/empublite/DownloadCheckService.java)

Here, we create a `Retrofit` instance, pointing to the server that is our "Web service" (really a static JSON file, but that does not matter from the standpoint of the client code). We then use the `Retrofit` instance to create an instance of a `BookUpdateInterface` implementation, code-generated by Retrofit. We then call `update()` on that object to get our `BookUpdateInfo`. If the date in the `updatedOn` field of our `BookUpdateInfo` is newer than `OUR_BOOK_DATE`, we return the `updateUrl` field of the `BookUpdateInfo`, which will be a URL pointing to a ZIP archive containing the updated book. If the `updatedOn` value is older than `OUR_BOOK_DATE`, we return `null` to signify that no updates are available.

This is not a particularly well-optimized approach. In particular, we never take into account that, once we have downloaded an update, we are only interested in updates newer than the one we downloaded. As it stands, we always compare the `updatedOn` value to `OUR_BOOK_DATE`, not the last `updatedOn` value that we used. A production-grade app would aim to handle this, such as by saving the last-used `updatedOn` value in a `SharedPreferences` and comparing against it, where available.

Finally, update `onHandleIntent()` to call `getUpdateUrl()`:

```
@Override
protected void onHandleIntent(Intent intent) {
  try {
    String url=getUpdateUrl();

    if (url != null) {
```

```
      // do something really cool here
    }
  }
  catch (Exception e) {
    Log.e(getClass().getSimpleName(),
          "Exception downloading update", e);
  }
}
```

Step #7: Downloading the Update

While the above code gets us the URL of the ZIP archive, it does not actually download it. We need more code to accomplish that.

Add a `private static final String` data member named `UPDATE_FILENAME` to `DownloadCheckService`, representing the name of the file for the downloaded ZIP file:

```
private static final String UPDATE_FILENAME="book.zip";
```

(from EmPubLite-AndroidStudio/T16-Update/EmPubLite/app/src/main/java/com/commonsware/empublite/DownloadCheckService.java)

Then, in `DownloadCheckService`, add the following `download()` method:

```
private File download(String url) throws IOException {
  File output=new File(getFilesDir(), UPDATE_FILENAME);

  if (output.exists()) {
    output.delete();
  }

  OkHttpClient client=new OkHttpClient();
  Request request=new Request.Builder().url(url).build();
  Response response=client.newCall(request).execute();
  BufferedSink sink=Okio.buffer(Okio.sink(output));

  sink.writeAll(response.body().source());
  sink.close();

  return(output);
}
```

(from EmPubLite-AndroidStudio/T16-Update/EmPubLite/app/src/main/java/com/commonsware/empublite/DownloadCheckService.java)

This method deletes the existing output file if it exists, then uses OkHttp (and its Okio transitive dependency) to download the book, writing the results to the designated output file.

Then, update `onHandleIntent()` in `DownloadCheckService` to call `download()` when we have something to download:

```
@Override
protected void onHandleIntent(Intent intent) {
  try {
    String url=getUpdateUrl();

    if (url != null) {
      File book=download(url);

      // do something almost as cool here

      book.delete();
    }
  }
  catch (Exception e) {
    Log.e(getClass().getSimpleName(),
          "Exception downloading update", e);
  }
}
```

Here, we delete the file after downloading it, so we do not clutter up our internal storage with the downloaded ZIP. This would appear to defeat the purpose of downloading the ZIP file in the first place, but we will add some code to use the ZIP file in the next step of the tutorial.

Step #8: Unpacking the Update

The last step in the book-download process is to unpack the ZIP archive onto internal storage, so we can start using the downloaded contents.

Add a `static final String` data member named `UPDATE_BASEDIR` to `DownloadCheckService`:

```
static final String UPDATE_BASEDIR="updates";
```

(from EmPubLite-AndroidStudio/T16-Update/EmPubLite/app/src/main/java/com/commonsware/empublite/DownloadCheckService.java)

This will point to the directory on internal storage where the latest book update will reside.

Then, update `onHandleIntent()` on `DownloadCheckService` once again, this time to add in a call to `ZipUtils.unzip()` and some other necessary changes:

```
@Override
protected void onHandleIntent(Intent intent) {
  try {
    String url=getUpdateUrl();

    if (url != null) {
      File book=download(url);
      File updateDir=new File(getFilesDir(), UPDATE_BASEDIR);

      updateDir.mkdirs();
      ZipUtils.unzip(book, updateDir);
      book.delete();
      EventBus.getDefault().post(new BookUpdatedEvent());
    }
  }
  catch (Exception e) {
    Log.e(getClass().getSimpleName(),
      "Exception downloading update", e);
  }
}
```

(from EmPubLite-AndroidStudio/T16-Update/EmPubLite/app/src/main/java/com/commonsware/empublite/DownloadCheckService.java)

Here, we:

- Create the `UPDATE_BASEDIR` directory if it does not already exist
- Call `ZipUtils.unzip()` to unZIP the ZIP file into that directory
- Post a `BookUpdatedEvent` to signify that a book update is ready

`ZipUtils` is a class from the CWAC-Security library that we added to our project back in Tutorial #6. Its `unzip()` method handles a variety of possible flaws in the ZIP archive that might be injected by an attacker who is intercepting our communications with the book update server.

Despite that, this update logic is a bit sloppy. It is possible that different book updates will have different files, and our `UPDATE_BASEDIR` will have some extra files as a result. Ideally, we should clean out `UPDATE_BASEDIR` before unpacking the ZIP

archive. Adding in some recursive delete-all-the-files-in-a-directory logic is left as an exercise for the reader.

At this point, `DownloadCheckService` should resemble:

```
package com.commonsware.empublite;

import android.app.IntentService;
import android.content.Intent;
import android.util.Log;
import com.commonsware.cwac.security.ZipUtils;
import org.greenrobot.eventbus.EventBus;
import java.io.File;
import java.io.IOException;
import okhttp3.OkHttpClient;
import okhttp3.Request;
import okhttp3.Response;
import okio.BufferedSink;
import okio.Okio;
import retrofit2.Retrofit;
import retrofit2.converter.gson.GsonConverterFactory;

public class DownloadCheckService extends IntentService {
  private static final String OUR_BOOK_DATE="20120418";
  private static final String UPDATE_FILENAME="book.zip";
  static final String UPDATE_BASEDIR="updates";

  public DownloadCheckService() {
    super("DownloadCheckService");
  }

  @Override
  protected void onHandleIntent(Intent intent) {
    try {
      String url=getUpdateUrl();

      if (url != null) {
        File book=download(url);
        File updateDir=new File(getFilesDir(), UPDATE_BASEDIR);

        updateDir.mkdirs();
        ZipUtils.unzip(book, updateDir);
        book.delete();
        EventBus.getDefault().post(new BookUpdatedEvent());
      }
    }
    catch (Exception e) {
```

```
      Log.e(getClass().getSimpleName(),
        "Exception downloading update", e);
    }
  }

  private String getUpdateUrl() throws IOException {
    Retrofit retrofit=
      new Retrofit.Builder()
        .baseUrl("https://commonsware.com")
        .addConverterFactory(GsonConverterFactory.create())
        .build();
    BookUpdateInterface updateInterface=
      retrofit.create(BookUpdateInterface.class);
    BookUpdateInfo info=updateInterface.update().execute().body();

    if (info.updatedOn.compareTo(OUR_BOOK_DATE) > 0) {
      return(info.updateUrl);
    }

    return(null);
  }

  private File download(String url) throws IOException {
    File output=new File(getFilesDir(), UPDATE_FILENAME);

    if (output.exists()) {
      output.delete();
    }

    OkHttpClient client=new OkHttpClient();
    Request request=new Request.Builder().url(url).build();
    Response response=client.newCall(request).execute();
    BufferedSink sink=Okio.buffer(Okio.sink(output));

    sink.writeAll(response.body().source());
    sink.close();

    return(output);
  }
}
```

(from EmPubLite-AndroidStudio/T16-Update/EmPubLite/app/src/main/java/com/commonsware/empublite/DownloadCheckService.java)

Step #9: Using the Update

All this work is nice. However, nothing else in the app knows about this `UPDATE_BASEDIR` copy of the book to actually display it.

In fact, we have two scenarios to consider:

- The user taps the update action bar item, and we download the update and want to show the updated book to the user right now
- Later on, when the user opens the book, we need to realize that we already have an update and use it, rather than using the copy baked into the APK

That will require some changes to our data model, how we populate it from `ModelFragment`, and how we use the results in our `ContentsAdapter`.

First, add a `File baseDir` data member to `BookContents`, along with an accompanying setter method:

```
File baseDir=null;

void setBaseDir(File baseDir) {
  this.baseDir=baseDir;
}
```

(from EmPubLite-AndroidStudio/T16-Update/EmPubLite/app/src/main/java/com/commonsware/empublite/BookContents.java)

Then, add a `getChapterPath()` method to `BookContents` that uses `getChapterFile()` for getting the relative path from the book's JSON, then uses that in conjunction with `baseDir` or the `android_asset` path to come up with a full `WebView`-friendly path to the file, whether it is in assets or a local file:

```
String getChapterPath(int position) {
  String file=getChapterFile(position);

  if (baseDir==null) {
    return("file:///android_asset/book/" + file);
  }

  return(Uri.fromFile(new File(baseDir, file)).toString());
}
```

(from EmPubLite-AndroidStudio/T16-Update/EmPubLite/app/src/main/java/com/commonsware/empublite/BookContents.java)

Next, change the `getItem()` method on `ContentsAdapter` to use this new `getChapterPath()` method on `BookContents`:

```
@Override
public Fragment getItem(int position) {
  return(SimpleContentFragment.newInstance(contents.getChapterPath(position)));
}
```

(from EmPubLite-AndroidStudio/T16-Update/EmPubLite/app/src/main/java/com/commonsware/empublite/ContentsAdapter.java)

Then, modify the `run()` method of the `LoadThread` in `ModelFragment` to try to use the update:

```
    @Override
    public void run() {
      prefs.set(PreferenceManager.getDefaultSharedPreferences(ctxt));

      Process.setThreadPriority(Process.THREAD_PRIORITY_BACKGROUND);
      Gson gson=new Gson();
      File baseDir=
        new File(ctxt.getFilesDir(),
          DownloadCheckService.UPDATE_BASEDIR);

      try {
        InputStream is;

        if (baseDir.exists()) {
          is=new FileInputStream(new File(baseDir, "contents.json"));
        }
        else {
          is=ctxt.getAssets().open("book/contents.json");
        }

        BufferedReader reader=
          new BufferedReader(new InputStreamReader(is));

        contents.set(gson.fromJson(reader, BookContents.class));

        if (baseDir.exists()) {
          contents.get().setBaseDir(baseDir);
        }

        EventBus.getDefault().post(new BookLoadedEvent(getBook()));
      }
      catch (IOException e) {
        Log.e(getClass().getSimpleName(), "Exception parsing JSON", e);
      }
```

```
    }
  }
```

(from EmPubLite-AndroidStudio/T16-Update/EmPubLite/app/src/main/java/com/commonsware/empublite/ModelFragment.java)

Here, we do the following, in addition to our original logic:

- See if the `UPDATE_BASEDIR` directory exists or not
- If it does, we use the `contents.json` in it; otherwise, we fall back to the one in `assets/` as before
- Update the `BookContents` with the update directory if we used that for loading the contents

This will handle the case where an update exists when we fire up the app and go to view the book. However, we still need some code that responds to the `BookUpdatedEvent` and arranges to use the updated contents at that point.

With that in mind, augment `onAttach()` on `ModelFragment` to register with the `EventBus`:

```
@Override
public void onAttach(Activity host) {
  super.onAttach(host);

  EventBus.getDefault().register(this);

  if (contents.get()==null) {
    new LoadThread(host).start();
  }
}
```

(from EmPubLite-AndroidStudio/T16-Update/EmPubLite/app/src/main/java/com/commonsware/empublite/ModelFragment.java)

We also now need a corresponding `onDetach()` method on `ModelFragment` to unregister from the `EventBus`:

```
@Override
public void onDetach() {
  EventBus.getDefault().unregister(this);

  super.onDetach();
}
```

(from EmPubLite-AndroidStudio/T16-Update/EmPubLite/app/src/main/java/com/commonsware/empublite/ModelFragment.java)

Finally, we can respond to the `BookUpdatedEvent`, via a new `onEventBackgroundThread()` method on `ModelFragment`:

```
@SuppressWarnings("unused")
@Subscribe(threadMode =ThreadMode.BACKGROUND)
public void onBookUpdated(BookUpdatedEvent event) {
  if (getActivity()!=null) {
    new LoadThread(getActivity()).start();
  }
}
```

(from EmPubLite-AndroidStudio/T16-Update/EmPubLite/app/src/main/java/com/commonsware/empublite/ModelFragment.java)

The name `threadMode =ThreadMode.BACKGROUND` signals to the `EventBus` that we want to receive this event on a background thread. In our case, the event is posted on a background thread (the one from the `IntentService`). Hence, our `onBookUpdated()` method is called on that thread. If, however, we were to post a `BookUpdatedEvent` from the main application thread, `EventBus` would deliver our `BookUpdatedEvent` to `onBookUpdated()` on an `EventBus`-supplied background thread, to ensure that we do not tie up the main application thread.

Here, we just kick off a fresh `LoadThread` to reload the `BookContents`, assuming that the user has not just pressed BACK or otherwise destroyed our activity. The new `LoadThread` will see that the update is available and use it, posting its own event to have our UI layer apply the update to the screen.

At this point, if you build and run the app, you will see the update action bar item:

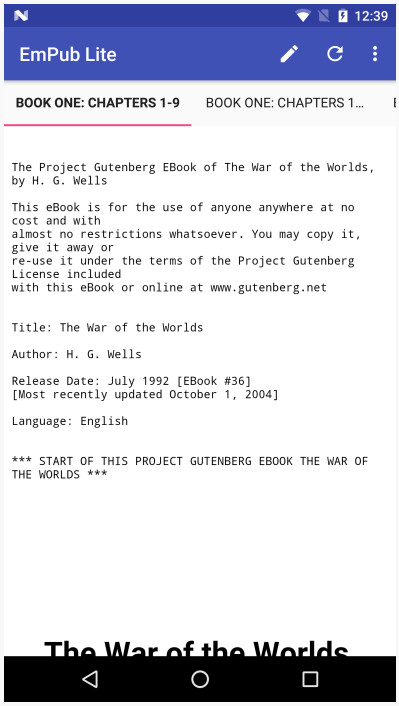

Figure 310: The New Action Bar Item

Swiping back to the first page in the `ViewPager`, tapping that action bar item, and waiting a few moments, should cause your book to be updated with new contents downloaded from the Internet:

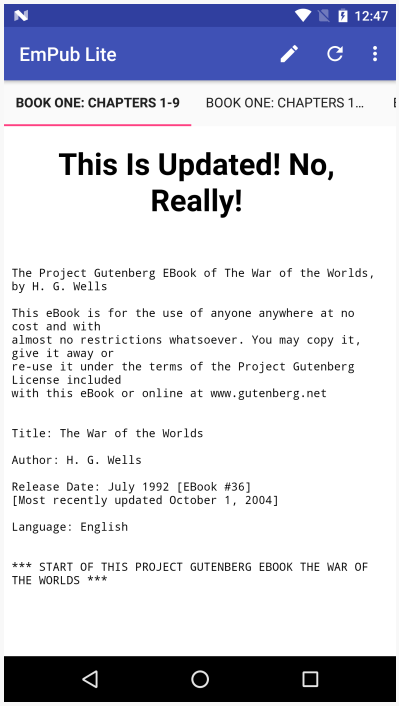

Figure 311: The Updated Content

In Our Next Episode…

… we will move some fragments into a sidebar on large-screen devices, like tablets.

Large-Screen Strategies and Tactics

So far, we have been generally ignoring screen size. With the vast majority of Android devices being in a fairly narrow range of sizes (3" to just under 5"), ignoring size while learning is not a bad approach. However, when it comes time to create a production app, you are going to want to strongly consider how you are going to handle other sizes, mostly larger ones (e.g., tablets).

Objective: Maximum Gain, Minimum Pain

What you want is to be able to provide a high-quality user experience without breaking your development budget — time *and* money — in the process.

An app designed around a phone, by default, may look fairly lousy on a tablet. That is because Android is simply going to try to stretch your layouts and such to fill the available space. While that will work, technically, the results may be unpleasant, or at least ineffective. If we have the additional room, it would be nice to allow the user to do something with that room.

At the same time, though, you do not have an infinite amount of time to be dealing with all of this. After all, there are a variety of tablet sizes. While ~7" and ~10" screens are the most common, there are certainly others that are reasonably popular (e.g., Amazon's Kindle Fire HD 8.9").

The Fragment Strategy

Some apps will use the additional space of a large screen directly. For example, a painting app would use that space mostly to provide a larger drawing canvas upon which the user can attempt to become the next Rembrandt, Picasso, or Pollock. The

app might elect to make more tools available directly on the screen as well, versus requiring some sort of pop-up to appear to allow the user to change brush styles, choose a different color, and so forth.

However, this can be a lot of work.

Some apps can make a simplifying assumption: the tablet UI is really a bunch of phone-sized layouts, stitched together. For example, if you take a 10" tablet in landscape, it is about the same size as two or three phones side-by-side. Hence, one could imagine taking the smarts out of a few activities and having them be adjacent to one another on a tablet, versus having to be visible only one at a time as they are on phones.

For example, consider the original edition of the Gmail app for Android.

On a phone, you would see conversations in a particular label on one screen:

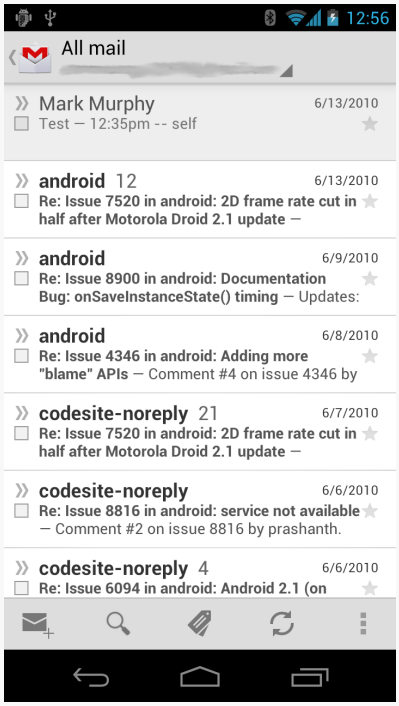

Figure 312: Gmail, On a Galaxy Nexus, Showing Conversations

... and the list of labels on another screen:

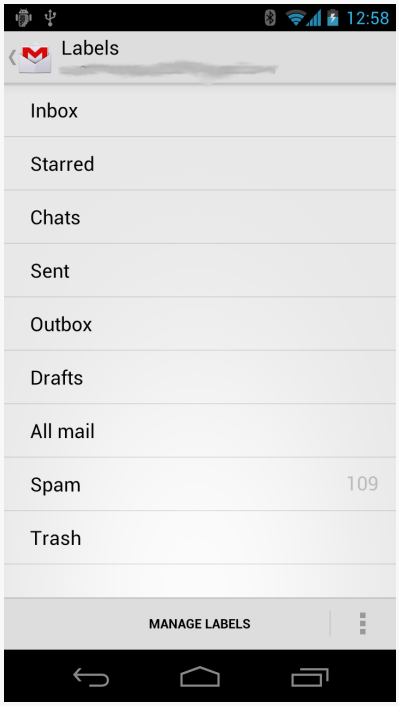

Figure 313: Gmail, On a Galaxy Nexus, Showing Labels

... and the list of messages in some selected conversation in a third screen:

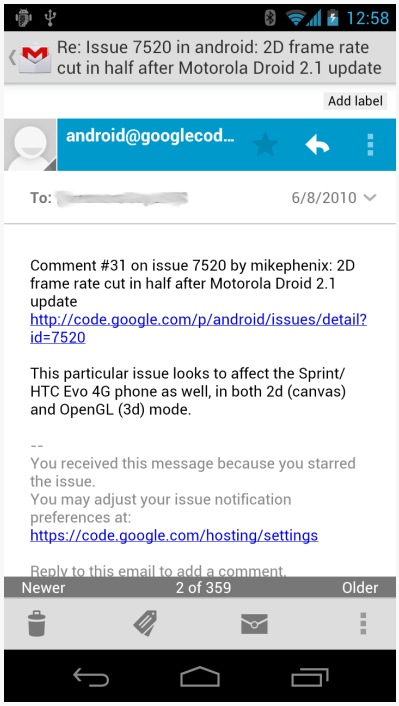

Figure 314: Gmail, On a Galaxy Nexus, Showing Messages

Whereas on a 7" tablet, you would see the list of labels and the conversations in a selected label at the same time:

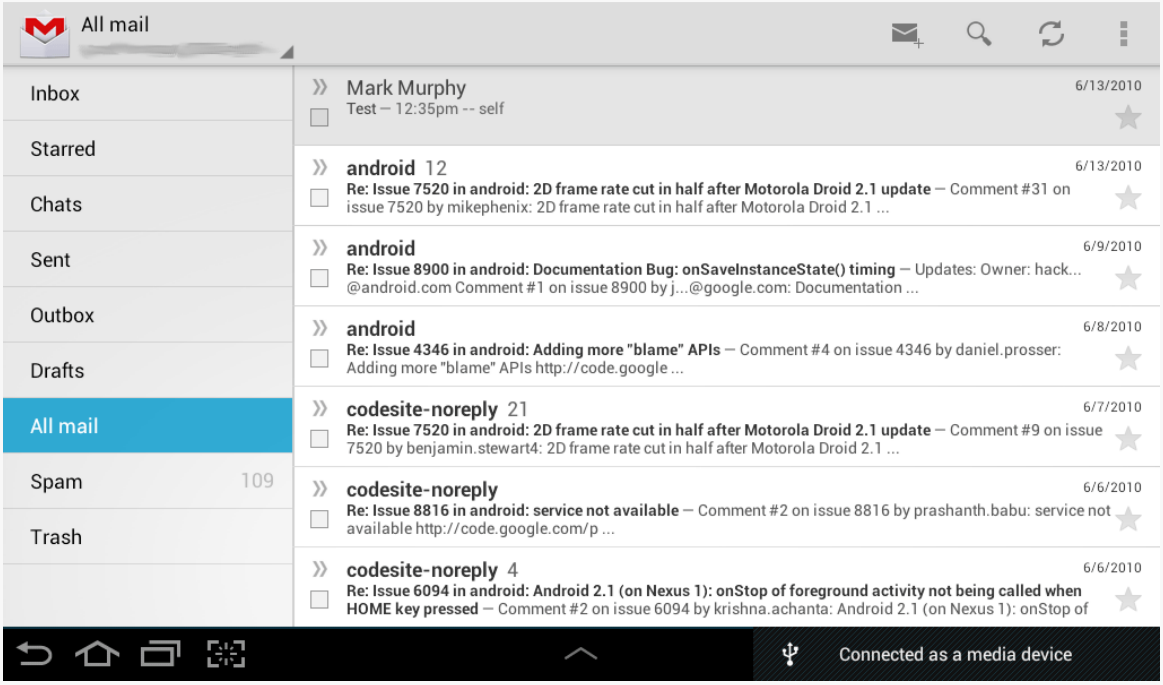

Figure 315: Gmail, On a Galaxy Tab 2, Showing Labels and Conversations

On that 7" tablet, tapping on a specific conversation brings up the list of messages for that conversation in a new screen. But, on a 10" tablet, tapping on a specific conversation showed that conversation, plus the list of conversations, side-by-side:

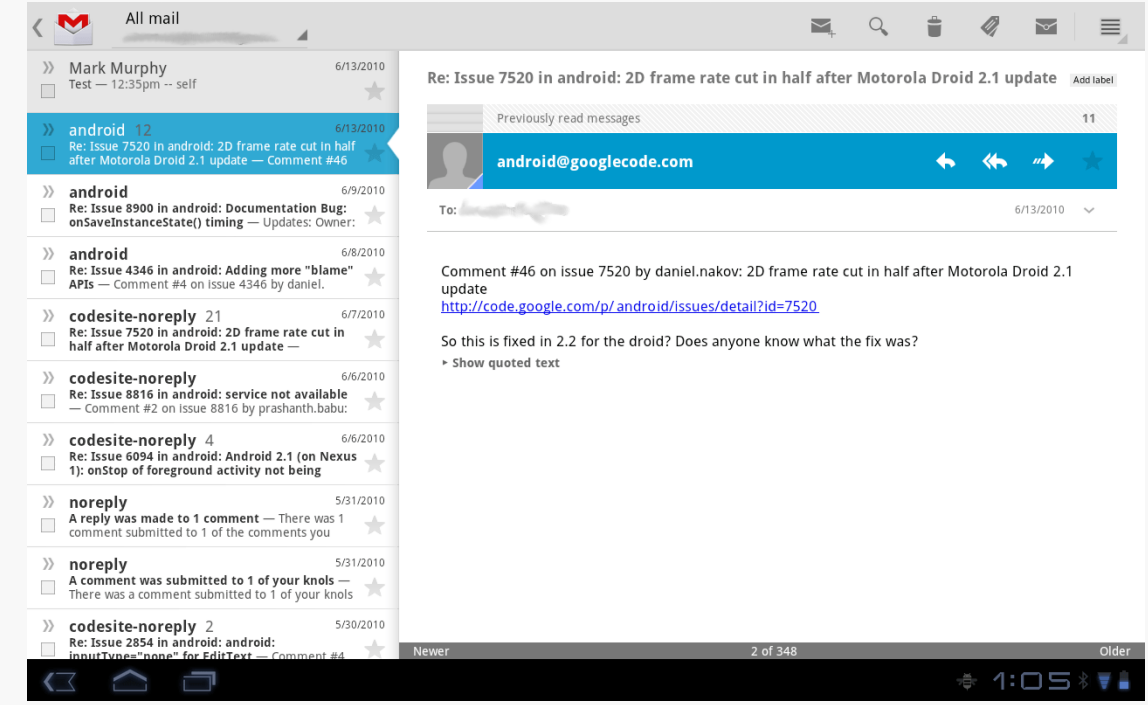

Figure 316: Gmail, On a Motorola XOOM, Showing Conversations and Messages

Yet all of that was done with one app with very little redundant logic, by means of fragments.

The list-of-labels, list-of-conversations, and list-of-messages bits of the UI were implemented as fragments. On a smaller screen (e.g., a phone), each one is displayed by an individual activity. Yet, on a larger screen (e.g., a tablet), more than one fragment is displayed by a single activity. In fact — though it will not be apparent from the static screenshots — on the 10" tablet, the activity showed *all three fragments*, using animated effects to slide the list of labels off-screen and the list of conversations over to the left slot when the user taps on a conversation to show the messages.

The vision, therefore, is to organize your UI into fragments, then choose which fragments to show in which circumstances based on available screen space:

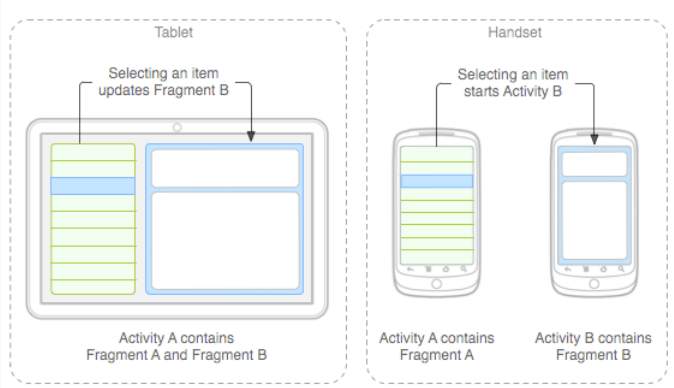

Figure 317: Tablets vs. Handsets (image courtesy of Android Open Source Project)

Changing Layout

One solution is to say that you have the same fragments for all devices and all configurations, but that the sizing and positioning of those fragments varies. This is accomplished by using different layouts for the activity, ones that provide the sizing and positioning rules for the fragments.

So far, most of our fragment examples have been focused on activities with a single fragment, like you might use on smaller screens (e.g., phones). However, activities can most certainly have more than one fragment, though you will need to provide the "slots" into which to plug those fragments.

For example, you could have the following in `res/layout-w720dp/main.xml`:

```
<?xml version="1.0" encoding="utf-8"?>
<LinearLayout
  xmlns:android="http://schemas.android.com/apk/res/android"
  android:orientation="horizontal"
  android:layout_width="match_parent"
  android:layout_height="match_parent">
  <FrameLayout
    android:id="@+id/countries"
    android:layout_weight="30"
    android:layout_width="0px"
    android:layout_height="match_parent"
  />
  <FrameLayout
    android:id="@+id/details"
    android:layout_weight="70"
    android:layout_width="0px"
```

```
    android:layout_height="match_parent"
  />
</LinearLayout>
```

(from LargeScreen/EU4You/app/src/main/res/layout-w720dp/main.xml)

Here we have a horizontal `LinearLayout` holding a pair of `FrameLayout` containers. Each of those `FrameLayout` containers will be a slot to load in a fragment, using code like:

```
getSupportFragmentManager().beginTransaction()
                                .add(R.id.countries, someFragmentHere)
                                .commit();
```

In principle, you could also have a `res/layout-h720dp/main.xml` that holds both of the same `FrameLayout` containers, but just in a `vertical` `LinearLayout`:

```
<?xml version="1.0" encoding="utf-8"?>
<LinearLayout
  xmlns:android="http://schemas.android.com/apk/res/android"
  android:orientation="vertical"
  android:layout_width="match_parent"
  android:layout_height="match_parent">
  <FrameLayout
    android:id="@+id/countries"
    android:layout_weight="30"
    android:layout_height="0dp"
    android:layout_width="match_parent"
  />
  <FrameLayout
    android:id="@+id/details"
    android:layout_weight="70"
    android:layout_height="0dp"
    android:layout_width="match_parent"
  />
</LinearLayout>
```

As the user rotates the device, the fragments will go in their appropriate slots.

Changing Fragment Mix

However, for larger changes in screen size, you will probably need to have larger changes in your fragments. The most common pattern is to have fewer fragments on-screen for an activity on a smaller-screen device (e.g., one fragment at a time on

a phone) and more fragments on-screen for an activity on a larger-screen device (e.g., two fragments at a time on a tablet).

So, for example, as the counterpart to the `res/layout-w720dp/main.xml` shown in the previous section, you might have a `res/layout/main.xml` that looks like this:

```
<?xml version="1.0" encoding="utf-8"?>
<FrameLayout xmlns:android="http://schemas.android.com/apk/res/android"
  android:id="@+id/countries"
  android:layout_width="match_parent"
  android:layout_height="match_parent"
/>
```

(from LargeScreen/EU4You/app/src/main/res/layout/main.xml)

This provides a single slot, `R.id.countries`, for a fragment, one that fills the screen. For a larger-screen device, held in landscape, you would use the two-fragment layout; for anything else (e.g., tablet in portrait, or phone in any orientation), you would use the one-fragment layout.

Of course, the content that belongs in the second fragment would have to show up *somewhere*.

Sometimes, when you add another fragment for a large screen, you only want it to be there some of the time. For example, a digital book reader (like the one we are building in the tutorials) might normally take up the full screen with the reading fragment, but might display a sidebar fragment based upon an action bar item click or the like. If you would like the BACK button to reverse your `FragmentTransaction` that added the second fragment — so pressing BACK removes that fragment and returns you to the single-fragment setup — you can add `addToBackStack()` as part of your `FragmentTransaction` construction:

```
getSupportFragmentManager().beginTransaction()
                           .addToBackStack(null)
                           .replace(R.id.sidebar, f)
                           .commit();
```

We will see this in the next tutorial.

The Role of the Activity

So, what is the activity doing?

First, the activity is the one loading the overall layout, the one indicating which fragments should be loaded (e.g., the samples shown above). The activity is responsible for populating those "slots" with the appropriate fragments. It can determine which fragments to create based on which slots exist, so it would only try to create a fragment to go in `R.id.details` if there actually is an `R.id.details` slot to use.

Next, the activity is responsible for handling any events that are triggered by UI work in a fragment (e.g., user clicking on a `ListView` item), whose results should impact other fragments (e.g., displaying details of the clicked-upon `ListView` item). The activity knows which fragments exist at the present time. So, the activity can either call some method on the second fragment if it exists, or it can call `startActivity()` to pass control to another activity that will be responsible for the second fragment if it does not exist in the current activity.

Finally, the activity is generally responsible for any model data that spans multiple fragments. Whether that model data is held in a "model fragment" (as outlined in the chapter on fragments) or somewhere else is up to you.

Fragment Example: The List-and-Detail Pattern

This will make a bit more sense as we work through another example, this time focused on a common pattern: a list of something, where clicking on the list brings up details on the item that was clicked upon. On a larger-screen device, in landscape, both pieces are typically displayed at the same time, side-by-side. On smaller-screen devices, and sometimes even on larger-screen devices in portrait, only the list is initially visible — tapping on a list item brings up some other activity to display the details.

Describing the App

The sample app for this section is `LargeScreen/EU4You`. This app has a list of member nations of the European Union (EU). Tapping on a member nation will display the mobile Wikipedia page for that nation in a `WebView` widget.

The data model — such as it is and what there is of it — consists of a `Country` class which holds onto the country name (as a string resource ID), flag (as a drawable resource ID), and mobile Wikipedia URL (as another string resource ID):

```
Country(int name, int flag, int url) {
  this.name=name;
  this.flag=flag;
  this.url=url;
}
```

The `Country` class has a static `ArrayList` of `Country` objects representing the whole of the EU, initialized in a static initialization block:

```
  static {
    EU.add(new Country(R.string.austria, R.drawable.austria,
                       R.string.austria_url));
    EU.add(new Country(R.string.belgium, R.drawable.belgium,
                       R.string.belgium_url));
    EU.add(new Country(R.string.bulgaria, R.drawable.bulgaria,
                       R.string.bulgaria_url));
    EU.add(new Country(R.string.cyprus, R.drawable.cyprus,
                       R.string.cyprus_url));
    EU.add(new Country(R.string.czech_republic,
                       R.drawable.czech_republic,
                       R.string.czech_republic_url));
    EU.add(new Country(R.string.denmark, R.drawable.denmark,
                       R.string.denmark_url));
    EU.add(new Country(R.string.estonia, R.drawable.estonia,
                       R.string.estonia_url));
    EU.add(new Country(R.string.finland, R.drawable.finland,
                       R.string.finland_url));
    EU.add(new Country(R.string.france, R.drawable.france,
                       R.string.france_url));
    EU.add(new Country(R.string.germany, R.drawable.germany,
                       R.string.germany_url));
    EU.add(new Country(R.string.greece, R.drawable.greece,
                       R.string.greece_url));
    EU.add(new Country(R.string.hungary, R.drawable.hungary,
                       R.string.hungary_url));
    EU.add(new Country(R.string.ireland, R.drawable.ireland,
                       R.string.ireland_url));
    EU.add(new Country(R.string.italy, R.drawable.italy,
                       R.string.italy_url));
    EU.add(new Country(R.string.latvia, R.drawable.latvia,
                       R.string.latvia_url));
    EU.add(new Country(R.string.lithuania, R.drawable.lithuania,
                       R.string.lithuania_url));
    EU.add(new Country(R.string.luxembourg, R.drawable.luxembourg,
                       R.string.luxembourg_url));
    EU.add(new Country(R.string.malta, R.drawable.malta,
                       R.string.malta_url));
```

```
    EU.add(new Country(R.string.netherlands, R.drawable.netherlands,
                       R.string.netherlands_url));
    EU.add(new Country(R.string.poland, R.drawable.poland,
                       R.string.poland_url));
    EU.add(new Country(R.string.portugal, R.drawable.portugal,
                       R.string.portugal_url));
    EU.add(new Country(R.string.romania, R.drawable.romania,
                       R.string.romania_url));
    EU.add(new Country(R.string.slovakia, R.drawable.slovakia,
                       R.string.slovakia_url));
    EU.add(new Country(R.string.slovenia, R.drawable.slovenia,
                       R.string.slovenia_url));
    EU.add(new Country(R.string.spain, R.drawable.spain,
                       R.string.spain_url));
    EU.add(new Country(R.string.sweden, R.drawable.sweden,
                       R.string.sweden_url));
    EU.add(new Country(R.string.united_kingdom,
                       R.drawable.united_kingdom,
                       R.string.united_kingdom_url));
  }
```

(from LargeScreen/EU4You/app/src/main/java/com/commonsware/android/eu4you/Country.java)

CountriesFragment

The fragment responsible for rendering the list of EU nations is `CountriesFragment`. It is a `ListFragment`, using a `CountryAdapter` to populate the list:

```
class CountryAdapter extends ArrayAdapter<Country> {
  CountryAdapter() {
    super(getActivity(), R.layout.row, R.id.name, Country.EU);
  }

  @Override
  public View getView(int position, View convertView, ViewGroup parent) {
    CountryViewHolder wrapper=null;

    if (convertView == null) {
      convertView=
          LayoutInflater.from(getActivity()).inflate(R.layout.row,
                                                     parent, false);
      wrapper=new CountryViewHolder(convertView);
      convertView.setTag(wrapper);
    }
    else {
      wrapper=(CountryViewHolder)convertView.getTag();
    }
```

```
      wrapper.populateFrom(getItem(position));

      return(convertView);
    }
  }
```

(from LargeScreen/EU4You/app/src/main/java/com/commonsware/android/eu4you/CountriesFragment.java)

This adapter is somewhat more complex than the ones we showed in the chapter on selection widgets. We will get into what `CountryAdapter` is doing, and the `CountryViewHolder` it references, in a later chapter of this book. Suffice it to say for now that the rows in the list contain both the country name and its flag.

When the user taps on a row in our `ListView`, something needs to happen – specifically, the details of that country need to be displayed. However, displaying those details is not the responsibility of `CountriesFragment`, as it simply displays the list of countries and nothing else. Hence, we need to pass the event up to the hosting activity to handle.

We could accomplish this using an event bus, as seen in other examples earlier in the book. The `EU4You` series of samples, though, use a different approach, referred to as the contract pattern. In this pattern, the fragment defines an interface, which is the "contract" that all hosting activities of that fragment must implement. This requirement is enforced by the superclass, `ContractListFragment`:

```

  Covered in detail in the book _The Busy Coder's Guide to Android Development_
    https://commonsware.com/Android
 */

// derived from https://gist.github.com/JakeWharton/2621173

package com.commonsware.android.eu4you;
```

```
import android.app.Activity;
import android.app.ListFragment;

public class ContractListFragment<T> extends ListFragment {
  private T contract;

  @SuppressWarnings("unchecked")
  @Override
  public void onAttach(Activity activity) {
    super.onAttach(activity);

    try {
      contract=(T)activity;
    }
    catch (ClassCastException e) {
      throw new IllegalStateException(activity.getClass()
                                              .getSimpleName()
          + " does not implement contract interface for "
          + getClass().getSimpleName(), e);
    }
  }

  @Override
  public void onDetach() {
    super.onDetach();

    contract=null;
  }

  public final T getContract() {
    return(contract);
  }
}
```

(from LargeScreen/EU4You/app/src/main/java/com/commonsware/android/eu4you/ContractListFragment.java)

`onAttach()` is called when the fragment has been attached to an activity, whether that is from when the activity was initially created, after a configuration change, or whenever. In those cases, we cast the activity to be the contract interface (provided via the data type in the declaration), raising an exception if the cast fails. Subclasses can then access the contract object via the `getContract()` method.

`CountriesFragment` inherits from `ContractListFragment` and defines its contract. Hence, any activity that hosts a `CountriesFragment` is responsible for implementing

this contract interface, so we can call `onCountrySelected()` when the user clicks on a row in the list:

```
  @Override
  public void onListItemClick(ListView l, View v, int position, long id) {
    if (getContract().isPersistentSelection()) {
      getListView().setChoiceMode(ListView.CHOICE_MODE_SINGLE);
      l.setItemChecked(position, true);
    }
    else {
      getListView().setChoiceMode(ListView.CHOICE_MODE_NONE);
    }

    getContract().onCountrySelected(Country.EU.get(position));
  }
```

(from LargeScreen/EU4You/app/src/main/java/com/commonsware/android/eu4you/CountriesFragment.java)

`CountriesFragment` also has quite a bit of code dealing with clicked-upon rows being in an "activated" state. This provides visual context to the user and is often used in the list-and-details pattern. For example, in the tablet renditions of Gmail shown earlier in this chapter, you will notice that the list on the left (e.g., list of labels) has one row highlighted with a blue background. This is the "activated" row, and it indicates the context for the material in the adjacent fragment (e.g., list of conversations in the label). Managing this "activated" state is a bit beyond the scope of this section, however, so we will delay discussion of that topic to a later chapter in this book.

DetailsFragment

The details to be displayed come in the form of a URL to a mobile Wikipedia page for a country, designed to be displayed in a `WebView`. The EU4You sample app makes use of the same `WebViewFragment` that we saw earlier in this book, such as in the tutorials. `DetailsFragment` itself, therefore, simply needs to expose some method to allow a hosting activity to tell it what URL to display:

```
package com.commonsware.android.eu4you;

import android.os.Bundle;
import android.view.View;
import android.webkit.WebView;
import android.webkit.WebViewClient;
import android.webkit.WebViewFragment;
```

```
public class DetailsFragment extends WebViewFragment {
  @Override
  public void onViewCreated(View view, Bundle savedInstanceState) {
    super.onViewCreated(view, savedInstanceState);

    getWebView().setWebViewClient(new URLHandler());
  }

  public void loadUrl(String url) {
    getWebView().loadUrl(url);
  }

  private static class URLHandler extends WebViewClient {
    @Override
    public boolean shouldOverrideUrlLoading(WebView view, String url) {
      view.loadUrl(url);

      return(true);
    }
  }
}
```

(from LargeScreen/EU4You/app/src/main/java/com/commonsware/android/eu4you/DetailsFragment.java)

You will notice that this fragment is not retained via `setRetainInstance()`. That is because, as you will see, we will not always be displaying this fragment. Fragments that are displayed in some configurations (e.g., landscape) but not in others (e.g., portrait), where a device might change between those configurations at runtime, cannot be retained without causing crashes.

You will also notice that this fragment uses `setWebViewClient()` to associate a `URLHandler` with the `WebView`. This `URLHandler` class simply forces all URLs back into the `WebView`, as opposed to launching a browser. Wikipedia now uses HTTPS for many pages, and it uses HTTP Strict Transport Security (HSTS) to redirect HTTP requests to their HTTPS counterparts as appropriate. The mobile Wikipedia URLs used in the app all have the `https` scheme, and so in theory there should be no server-side redirects. But, just in case, the `URLHandler` ensures that such redirects will stay within the `WebView`.

The Activities

Our launcher activity is also named `EU4You`. It uses two of the layouts shown above. Both are `main.xml`, but one is in `res/layout-w720dp/`:

```
<?xml version="1.0" encoding="utf-8"?>
<LinearLayout
  xmlns:android="http://schemas.android.com/apk/res/android"
  android:orientation="horizontal"
  android:layout_width="match_parent"
  android:layout_height="match_parent">
  <FrameLayout
    android:id="@+id/countries"
    android:layout_weight="30"
    android:layout_width="0px"
    android:layout_height="match_parent"
  />
  <FrameLayout
    android:id="@+id/details"
    android:layout_weight="70"
    android:layout_width="0px"
    android:layout_height="match_parent"
  />
</LinearLayout>
```

(from LargeScreen/EU4You/app/src/main/res/layout-w720dp/main.xml)

The other is in `res/layout/`:

```
<?xml version="1.0" encoding="utf-8"?>
<FrameLayout xmlns:android="http://schemas.android.com/apk/res/android"
  android:id="@+id/countries"
  android:layout_width="match_parent"
  android:layout_height="match_parent"
/>
```

(from LargeScreen/EU4You/app/src/main/res/layout/main.xml)

Both have a `FrameLayout` for the `CountriesFragment` (`R.id.countries`), but only the `res/layout-w720dp/` edition has a `FrameLayout` for the `DetailsFragment` (`R.id.details`).

Here is the complete implementation of the `EU4You` activity:

```
package com.commonsware.android.eu4you;

import android.app.Activity;
import android.content.Intent;
import android.os.Bundle;

public class EU4You extends Activity implements
    CountriesFragment.Contract {
  private CountriesFragment countries=null;
  private DetailsFragment details=null;
```

```
  @Override
  public void onCreate(Bundle savedInstanceState) {
    super.onCreate(savedInstanceState);
    setContentView(R.layout.main);

    countries=
        (CountriesFragment)getFragmentManager().findFragmentById(R.id.countries);

    if (countries == null) {
      countries=new CountriesFragment();
      getFragmentManager().beginTransaction()
                                  .add(R.id.countries, countries)
                                  .commit();
    }

    details=
        (DetailsFragment)getFragmentManager().findFragmentById(R.id.details);

    if (details == null && findViewById(R.id.details) != null) {
      details=new DetailsFragment();
      getFragmentManager().beginTransaction()
                                  .add(R.id.details, details).commit();
    }
  }

  @Override
  public void onCountrySelected(Country c) {
    String url=getString(c.url);

    if (details != null && details.isVisible()) {
      details.loadUrl(url);
    }
    else {
      Intent i=new Intent(this, DetailsActivity.class);

      i.putExtra(DetailsActivity.EXTRA_URL, url);
      startActivity(i);
    }
  }

  @Override
  public boolean isPersistentSelection() {
    return(details != null && details.isVisible());
  }
}
```

(from LargeScreen/EU4You/app/src/main/java/com/commonsware/android/eu4you/EU4You.java)

The job of `onCreate()` is to set up the UI. So, we:

- See if we already have an instance of `CountriesFragment`, by asking our `FragmentManager` to give us the fragment in the `R.id.countries` slot — this might occur if we underwent a configuration change, as `CountriesFragment` would be recreated in that case

- If we do not have a `CountriesFragment` instance, create one and execute a `FragmentTransaction` to load it into `R.id.countries` of our layout
- Find the `DetailsFragment` (which, since `DetailsFragment` is not retained, should always return `null`, but, as they say, "better safe than sorry")
- If we do not have a `DetailsFragment` *and* the layout has an `R.id.details` slot, create a `DetailsFragment` and execute the `FragmentTransaction` to put it in that slot... but otherwise do nothing

The net result is that `EU4You` can correctly handle either situation, where we have both fragments or just one.

Similarly, the `onCountrySelected()` method (required by the `Contract` interface) will see if we have our `DetailsFragment` or not (and whether it is visible, or is hidden because we created it but it is not visible in the current screen orientation). If we do, we just call `loadUrl()` on it, to populate the `WebView`. If we do not have a visible `DetailsFragment`, we need to do something to display one. In principle, we could elect to execute a `FragmentTransaction` to replace the `CountriesFragment` with the `DetailsFragment`, but this can get complicated. Here, we start up a separate `DetailsActivity`, passing the URL for the chosen `Country` in an `Intent` extra.

`DetailsActivity` is similar:

```
package com.commonsware.android.eu4you;

import android.app.Activity;
import android.os.Bundle;

public class DetailsActivity extends Activity {
  public static final String EXTRA_URL=
      "com.commonsware.android.eu4you.EXTRA_URL";
  private String url=null;
  private DetailsFragment details=null;

  @Override
  public void onCreate(Bundle savedInstanceState) {
    super.onCreate(savedInstanceState);

    details=(DetailsFragment)getFragmentManager()
                             .findFragmentById(android.R.id.content);

    if (details == null) {
      details=new DetailsFragment();

      getFragmentManager().beginTransaction()
```

```
                                .add(android.R.id.content, details)
                                .commit();
    }

    url=getIntent().getStringExtra(EXTRA_URL);
  }

  @Override
  public void onResume() {
    super.onResume();

    details.loadUrl(url);
  }
}
```

(from LargeScreen/EU4You/app/src/main/java/com/commonsware/android/eu4you/DetailsActivity.java)

We create the `DetailsFragment` and load it into the layout, capture the URL from the `Intent` extra, and call `loadUrl()` on the `DetailsFragment`. However, since we are executing a `FragmentTransaction`, the actual UI for the `DetailsFragment` is not created immediately, so we cannot call `loadUrl()` right away (otherwise, `DetailsFragment` will try to pass it to a non-existent `WebView`, and we crash). So, we delay calling `loadUrl()` to `onResume()`, at which point the `WebView` should exist.

The Results

On a larger-screen device, in landscape, we have both fragments, though there is nothing initially loaded into the `DetailsFragment`:

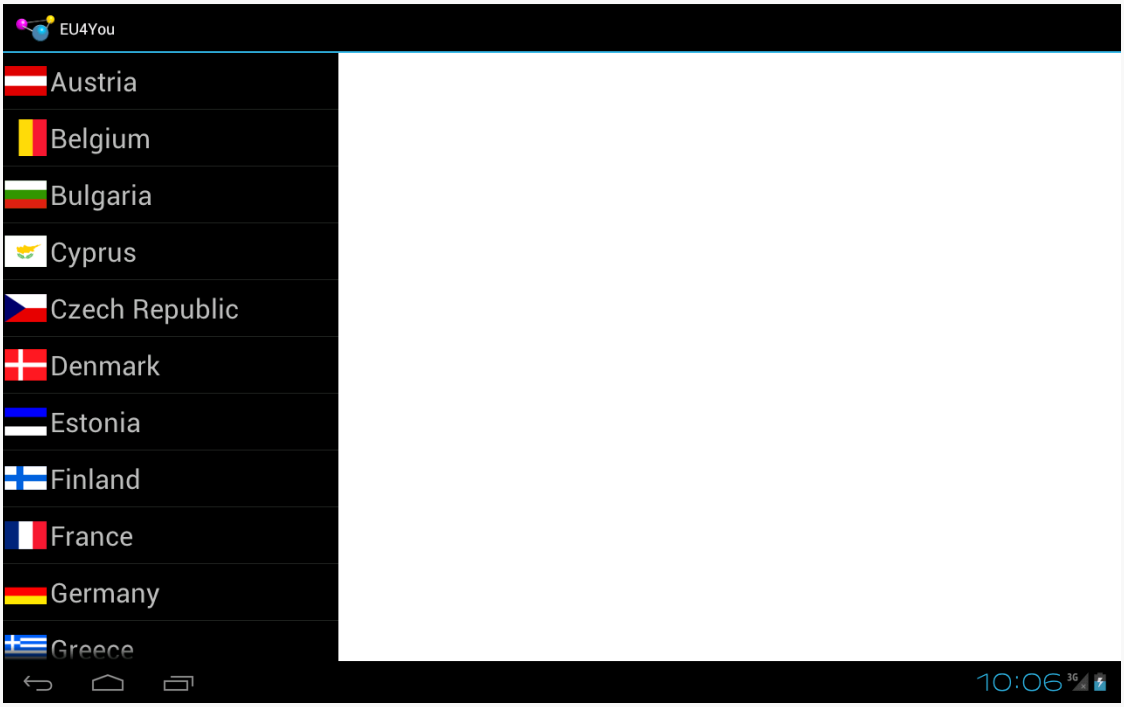

Figure 318: EU4You, On a Tablet Emulator, Landscape

Tapping on a country brings up the details on the right:

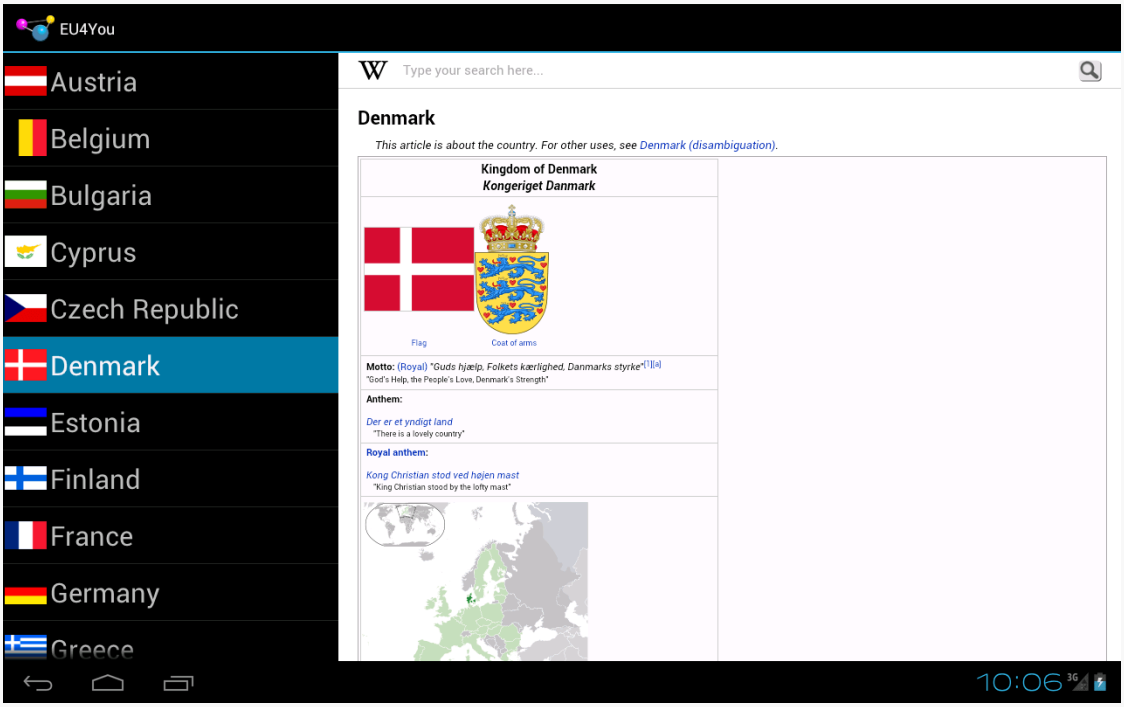

Figure 319: EU4You, On a Tablet Emulator, Landscape, With Details

In any other configuration, such as a smaller-screen device, we only see the `CountriesFragment` at the outset:

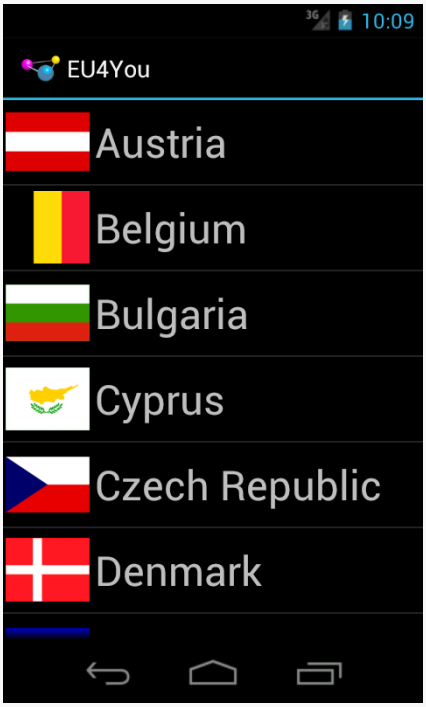

Figure 320: EU4You, On a Phone Emulator

Tapping on a country brings up the `DetailsFragment` full-screen in the `DetailsActivity`:

Figure 321: EU4You, On a Phone Emulator, Showing Details

Other Master-Detail Strategies

The EU4You sample from above is one way of approaching this master-detail pattern. It is not the only one. In this section, will we review other implementations of EU4You that use other techniques for implementating the master-detail pattern.

Static CountriesFragment

In the original `EU4You` activity, both fragments were dynamic, each added via a `FragmentTransaction`. `DetailsFragment` has to be dynamic, as whether or not it is visible depends upon screen size and orientation. However, there is no particular need for our `CountriesFragment` to be dynamic, as you will see in the `LargeScreen/EU4YouStaticCountries` sample project.

Here, our single-pane layout uses a `<fragment>` element to wire in the `CountriesFragment`:

```
<?xml version="1.0" encoding="utf-8"?>
<fragment xmlns:android="http://schemas.android.com/apk/res/android"
```

```
  android:id="@+id/countries"
  android:layout_width="match_parent"
  android:layout_height="match_parent"
  android:name="com.commonsware.android.eu4you3.CountriesFragment"
/>
```

(from LargeScreen/EU4YouStaticCountries/app/src/main/res/layout/main.xml)

Similarly, our dual-pane layout uses a `<fragment>` element for the `CountriesFragment`, alongside the `FrameLayout` for the details:

```
<?xml version="1.0" encoding="utf-8"?>
<LinearLayout xmlns:android="http://schemas.android.com/apk/res/android"
  android:layout_width="match_parent"
  android:layout_height="match_parent"
  android:baselineAligned="false"
  android:orientation="horizontal">

  <fragment
    android:id="@+id/countries"
    android:name="com.commonsware.android.eu4you3.CountriesFragment"
    android:layout_width="0px"
    android:layout_height="match_parent"
    android:layout_weight="30"/>

  <FrameLayout
    android:id="@+id/details"
    android:layout_width="0px"
    android:layout_height="match_parent"
    android:layout_weight="70"/>

</LinearLayout>
```

(from LargeScreen/EU4YouStaticCountries/app/src/main/res/layout-w720dp/main.xml)

Our `onCreate()` for `EU4You` is simpler, in that we do not need to mess with the `CountriesFragment` at all:

```
  @Override
  public void onCreate(Bundle savedInstanceState) {
    super.onCreate(savedInstanceState);
    setContentView(R.layout.main);

    details=
        (DetailsFragment)getFragmentManager().findFragmentById(R.id.details);

    if (details == null && findViewById(R.id.details) != null) {
```

```
      details=new DetailsFragment();
      getFragmentManager().beginTransaction()
                                  .add(R.id.details, details).commit();
    }
  }
```

(from LargeScreen/EU4YouStaticCountries/app/src/main/java/com/commonsware/android/eu4you3/EU4You.java)

Neither `CountriesFragment` or anything involving the details necessarily needs to change.

Going With One Activity

You might wonder why we need to bother with `DetailsActivity`. After all, the `EU4You` activity is perfectly capable of showing the `DetailsFragment` in a second pane — why not have it display the `DetailsFragment` in the first pane as well, in single-pane scenarios? Surely, this will be much simpler, as we can dispense with the activity and its entry in the manifest!

Yes, this is possible. No, it is not simpler.

The reason for the complexity is now managing all of our possible mix of fragments. We already had to deal with the following possibilities:

- Single-pane, showing the countries
- Single-pane, showing the countries, but on a large screen in portrait mode, after the activity had been launched in landscape, so the `DetailsFragment` exists in the `FragmentManager`, but is not visible
- Dual-pane, showing both fragments

If we get rid of `DetailsActivity` and dump all the responsibility onto `EU4You`, we have more scenarios:

- Single-pane, showing the details, having replaced the countries via a `FragmentTransaction`
- Single-pane, showing the countries, after having shown the details and the user then pressing BACK

Basically, what we must do now is `replace()` the `CountriesFragment` with the `DetailsFragment`, when we are in single-pane mode, when the user taps on a country in the list. This requires a fairly extensive number of changes, as you will see in the `LargeScreen/EU4YouSingleActivity` sample project.

The Revised Layouts

In our single-pane mode, our one pane will either hold the `CountriesFragment` or the `DetailsFragment`, depending upon what the user has done. Right now, our `FrameLayout` is named `R.id.countries`, which was fine before, but now seems like an inappropriate name. So, the new project's layouts change this to `R.id.mainfrag`, without changing anything else:

```
<?xml version="1.0" encoding="utf-8"?>
<FrameLayout xmlns:android="http://schemas.android.com/apk/res/android"
  android:id="@+id/mainfrag"
  android:layout_width="match_parent"
  android:layout_height="match_parent"
/>
```

(from LargeScreen/EU4YouSingleActivity/app/src/main/res/layout/main.xml)

The New onCountrySelected()

The "simple" part of the changes comes in the revised `onCountrySelected()` method in EU4You:

```
  @Override
  public void onCountrySelected(Country c) {
    String url=getString(c.url);

    details.loadUrl(url);

    if (details.getId() != R.id.details) {
      getFragmentManager().beginTransaction()
                          .replace(R.id.mainfrag, details,
                                   TAG_DETAILS)
                          .addToBackStack(null).commit();
    }
  }
```

(from LargeScreen/EU4YouSingleActivity/app/src/main/java/com/commonsware/android/eu4you2/EU4You.java)

In our revised scenario, we will *always* have a `DetailsFragment`. The question is merely whether it is presently visible. Hence, we can call `loadUrl()` on `details` directly.

However, there are two possible scenarios for the status of our `DetailsFragment` at the point in time of `onCountrySelected()` being called:

1. It exists in the `details` `FrameLayout` of our dual-pane layout resource
2. It exists, perhaps due to a configuration change, but is not presently in a container

You might think that there would be a third scenario, where it is the visible fragment in the `mainfrag` `FrameLayout`. Indeed, sometimes `DetailsFragment` will be in that container... just not now. The only time that `onCountrySelected()` will be called is if the user tapped on an item in our `CountriesFragment`, which means that `CountriesFragment` must be in `mainfrag`.

The ID of a fragment, from `getId()`, is the ID of its container, when used with dynamic fragments. So, we check to see whether our `DetailsFragment` is in the `details` `FrameLayout` by comparing ID values. If they differ, then we `commit()` a `replace()` `FragmentTransaction` to put `DetailsFragment` into `mainfrag`. Note, though, that we use `addToBackStack()`, so if the user presses the BACK button, we will roll back this transaction and return to the `CountriesFragment`.

The New onCreate()

If you thought that was messy, you will not like the changes required to `onCreate()` of `EU4You` much more:

```
@Override
public void onCreate(Bundle savedInstanceState) {
  super.onCreate(savedInstanceState);
  setContentView(R.layout.main);

  countries=
      (CountriesFragment)getFragmentManager().findFragmentByTag(TAG_COUNTRIES);
  details=
      (DetailsFragment)getFragmentManager().findFragmentByTag(TAG_DETAILS);

  if (countries == null) {
    countries=new CountriesFragment();
    getFragmentManager().beginTransaction()
                                .add(R.id.mainfrag, countries,
                                     TAG_COUNTRIES).commit();
  }

  if (details == null) {
    details=new DetailsFragment();

    if (findViewById(R.id.details) != null) {
      getFragmentManager().beginTransaction()
                                .add(R.id.details, details,
                                     TAG_DETAILS).commit();
    }
  }
  else {
```

```
    if (details.getId() == R.id.mainfrag) {
      if (findViewById(R.id.details) != null) {
        getFragmentManager().popBackStackImmediate();
      }
    }
    else {
      getFragmentManager().beginTransaction().remove(details)
                          .commit();
    }

    if (findViewById(R.id.details) != null) {
      getFragmentManager().beginTransaction()
                          .add(R.id.details, details,
                               TAG_DETAILS).commit();
    }
  }
}
```

(from LargeScreen/EU4YouSingleActivity/app/src/main/java/com/commonsware/android/eu4you2/EU4You.java)

This sample is derived from the original EU4You sample, and so we are still using a `FragmentTransaction` to set up the `CountriesFragment` in `mainfrag`, if we did not create `CountriesFragment` earlier.

Dealing with `DetailsFragment`, though, is decidedly more complicated. The flow that we want is if we were in dual-pane mode and switch to single-pane mode, that we show the `CountriesFragment` in that single pane. If we switch from single-pane mode to dual-pane mode, both fragments will be shown, of course.

First, we have the case where our `DetailsFragment` does not yet exist. This is much like the original sample: we need to create the fragment and put it into the `details` `FrameLayout`, if the `details` `FrameLayout` exists.

If the `DetailsFragment` exists, we need to make sure that it winds up in the `details` `FrameLayout`, if one exists.

To do that, we first check its ID to see if it is presently located in `mainfrag`. If it is, and if we have a `details` `FrameLayout`, we have switched to dual-pane mode and need to pop our back stack, in preparation for moving the `DetailsFragment` to the `details` `FrameLayout`.

If the `DetailsFragment` exists but is not in `mainfrag`, we `remove()` it entirely.

Then, if the `DetailsFragment` exists, regardless of where it was before, we `add()` it to the `details` `FrameLayout`.

The "OMG! Our Fragments Have No Views!" Changes

In testing, there are now scenarios in which `CountriesFragment` is called with `onSaveInstanceState()`, but without its views having been created (i.e., `onCreateView()` was not called). This would cause us to fail when trying to use `getListView()`, as that method would return `null`, since the `ListView` did not exist. So, we modify `onSaveInstanceState()` to be a bit more robust:

```
  @Override
  public void onSaveInstanceState(Bundle state) {
    super.onSaveInstanceState(state);

    if (getView() != null) {
      state.putInt(STATE_CHECKED,
                   getListView().getCheckedItemPosition());
    }
  }
```

(from LargeScreen/EU4YouSingleActivity/app/src/main/java/com/commonsware/android/eu4you2/CountriesFragment.java)

We also need to beef up `DetailsFragment` a bit. Before, we relied on the fact that, on a configuration change, our extras on our `Intent` for `DetailsActivity` would still be available. Now, though, there is no `DetailsActivity`, which means that `DetailsFragment` has to maintain its state, so that we do not lose the URL we were viewing when the user rotates the screen or causes another configuration change. And, to top it off, we have the same potential issue as with `CountriesFragment`, where the fragment might exist but not have `onCreateView()` called (e.g., we were in dual-pane mode and switched to single-pane mode, and `DetailsFragment` has not yet been displayed), so we cannot assume that `getWebView()` will always return a non-`null` value.

To that end, `DetailsFragment` gets complicated:

```
package com.commonsware.android.eu4you2;

import android.os.Bundle;
import android.view.View;
import android.webkit.WebView;
import android.webkit.WebViewClient;
import android.webkit.WebViewFragment;

public class DetailsFragment extends WebViewFragment {
  private static final String STATE_URL="url";
  private String url=null;
```

```
@Override
public void onViewCreated(View view, Bundle savedInstanceState) {
  super.onViewCreated(view, savedInstanceState);

  getWebView().setWebViewClient(new URLHandler());
}

@Override
public void onActivityCreated(Bundle savedInstanceState) {
  super.onActivityCreated(savedInstanceState);

  if (url == null && savedInstanceState != null) {
    url=savedInstanceState.getString(STATE_URL);
  }

  if (url != null) {
    loadUrl(url);
    url=null;
  }
}

@Override
public void onSaveInstanceState(Bundle outState) {
  super.onSaveInstanceState(outState);

  if (url == null) {
    outState.putString(STATE_URL, getWebView().getUrl());
  }
  else {
    outState.putString(STATE_URL, url);
  }
}

void loadUrl(String url) {
  if (getView() == null) {
    this.url=url;
  }
  else {
    getWebView().loadUrl(url);
  }
}

private static class URLHandler extends WebViewClient {
  @Override
  public boolean shouldOverrideUrlLoading(WebView view, String url) {
    view.loadUrl(url);

    return(true);
```

```
    }
  }
}
```

(from LargeScreen/EU4YouSingleActivity/app/src/main/java/com/commonsware/android/eu4you2/DetailsFragment.java)

The `url` data member will temporarily hold the URL of the page we should be viewing, particularly when we have no `WebView` to work with. So, our `loadUrl()` method now puts the URL into `url` if we have no `WebView` or loads it into the `WebView` if the `WebView` exists. `onSaveInstanceState()` will put the URL — whether from `url` or from the `WebView` — into the state `Bundle`. `onActivityCreated()` will attempt to populate `url` from the `Bundle` (if we do not already have a URL), then use that to populate the `WebView` (which should exist if `onActivityCreated()` is called). `url` is set to `null` to indicate that the `WebView` holds our URL, once that is completed.

The Results

From a user experience standpoint, things have not significantly changed. The user still sees the list, still sees the details when tapping on an entry in the list, and still gets the dual-pane experience on larger screens.

However, the transition between the list and the details in single-pane mode is a bit faster, as a `FragmentTransaction` takes less time than does starting up another activity. However, by default, our `FragmentTransaction` does not apply any transition effects, and so the fragment changes "just happen" without any fades, zooms, or the like. It is certainly possible to specify fragment transition effects, if desired, though this is outside the scope of this chapter.

The Mashup Possibilities

It should be possible to combine the two revised versions of EU4You, having a single activity manage all the fragments, with `CountriesFragment` set up as a static fragment. The proof that this is possible is left to the reader.

The SlidingPaneLayout Variant

The R13 update to the Android Support package introduced `SlidingPaneLayout`, another way of handling this sort of master-detail pattern. `SlidingPaneLayout` significantly reduces the level of effort for setting up master-detail, as it handles all

of the "dirty work" of showing the different fragments in different scenarios (normal screen, large screen, etc.).

The Role of SlidingPaneLayout

In the master-detail pattern, we are showing both the master and the detail fragment, side-by-side, on larger screens, while showing only one at a time on smaller screens. In the preceding examples, we had to manage all of that ourselves, in terms of deciding how many fragments to show and for switching between those fragments as needed.

`SlidingPaneLayout` encapsulates that logic.

`SlidingPaneLayout` will detect the screen size. If the screen size is big enough, `SlidingPaneLayout` will display its two children side-by-side. If the screen size is not big enough, `SlidingPaneLayout` will display one child at a time. However, by default, when the "master" child is visible, a thin strip on the right will allow the user to return to the "detail" child. Similarly, a swiping gesture can switch from the "detail" back to the "master" child. These are in addition to any changes in context you might introduce based on UI operations (e.g., tapping on an element in a master `ListView` automatically switching to the detail child).

Converting to SlidingPaneLayout

The `LargeScreen/EU4YouSlidingPane` sample project represents a rework of the EU4You core sample, this time using `SlidingPaneLayout` for handling the master-detail pattern.

Since `SlidingPaneLayout` encapsulates the master-detail logic, we can drop a lot of stuff that we used before but no longer need, including:

- `DetailsActivity` (as `SlidingPaneLayout` works akin to our single-activity implementation)
- the dedicated large-screen layout (as `SlidingPaneLayout` "bakes in" the logic for handling different screen sizes)
- dynamic fragments (as `SlidingPaneLayout` will work better with static fragments, anyway)
- `isPersistentSelection()` (as we will always want to use activated rows, on API Level 11+, as the user can more readily switch back and forth between

master and detail on smaller screens, and we want to indicate in the master what the context is that is displayed in the detail)

However, we did have to add a bit of pane management, plus move around some list-related behaviors in our `CountriesFragment`.

For starters, our `res/layout/main.xml` file now contains a `SlidingPaneLayout`, along with our two fragments, each set up as static `<fragment>` elements:

```
<?xml version="1.0" encoding="utf-8"?>
<android.support.v4.widget.SlidingPaneLayout xmlns:android="http://schemas.android.com/apk/res/android"
  android:id="@+id/panes"
  android:layout_width="match_parent"
  android:layout_height="match_parent">

  <fragment
    android:id="@+id/countries"
    android:name="com.commonsware.android.eu4you4.CountriesFragment"
    android:layout_width="300sp"
    android:layout_height="match_parent"/>

  <fragment
    android:id="@+id/details"
    android:name="com.commonsware.android.eu4you4.DetailsFragment"
    android:layout_width="400dp"
    android:layout_height="match_parent"
    android:layout_weight="1"/>

</android.support.v4.widget.SlidingPaneLayout>
```

(from LargeScreen/EU4YouSlidingPane/app/src/main/res/layout/main.xml)

By putting an `android:layout_weight` on our `details` fragment, we indicate that we want that one to take up all remaining room when the two fragments are shown side-by-side. You might think that we should then set the width of the `details` fragment to `0dp`; however, for some reason, this does not work.

The size of the `countries` (master) fragment will be honored on larger screens. On smaller screens, the size of the master fragment will be dictated by the width of the screen, minus a strip to allow the user to see a portion of the detail fragment and swipe that to display the detail fragment *in toto*.

Our `CountriesFragment` now always sets up the `ListView` to be single-choice mode, in `onActivityCreated()`. It also calls `onCountrySelected()` on our `CountriesFragment.Contract`, to ensure that the master is highlighting the last selection — this is needed to make sure that everything is displayed properly after a configuration change:

```
  @Override
  public void onActivityCreated(Bundle state) {
    super.onActivityCreated(state);

    setListAdapter(new CountryAdapter());
    getListView().setChoiceMode(ListView.CHOICE_MODE_SINGLE);

    if (state != null) {
      int position=state.getInt(STATE_CHECKED, -1);

      if (position > -1) {
        getListView().setItemChecked(position, true);
        getContract().onCountrySelected(Country.EU.get(position));
      }
    }
  }
```

(from LargeScreen/EU4YouSlidingPane/app/src/main/java/com/commonsware/android/eu4you4/CountriesFragment.java)

`onListItemClick()` of `CountriesFragment` becomes a bit simpler:

```
  @Override
  public void onListItemClick(ListView l, View v, int position, long id) {
    l.setItemChecked(position, true);
    getContract().onCountrySelected(Country.EU.get(position));
  }
```

(from LargeScreen/EU4YouSlidingPane/app/src/main/java/com/commonsware/android/eu4you4/CountriesFragment.java)

The `EU4You` activity overall becomes *substantially* simpler:

```
package com.commonsware.android.eu4you4;

import android.app.Activity;
import android.os.Bundle;
import android.support.v4.widget.SlidingPaneLayout;

public class EU4You extends Activity implements
    CountriesFragment.Contract {
  private DetailsFragment details=null;
  private SlidingPaneLayout panes=null;

  @Override
  public void onCreate(Bundle savedInstanceState) {
    super.onCreate(savedInstanceState);
    setContentView(R.layout.main);

    details=
```

```
        (DetailsFragment)getFragmentManager().findFragmentById(R.id.details);
    panes=(SlidingPaneLayout)findViewById(R.id.panes);
    panes.openPane();
  }

  @Override
  public void onBackPressed() {
    if (panes.isOpen()) {
      super.onBackPressed();
    }
    else {
      panes.openPane();
    }
  }

  @Override
  public void onCountrySelected(Country c) {
    details.loadUrl(getString(c.url));
    panes.closePane();
  }
}
```

(from LargeScreen/EU4YouSlidingPane/app/src/main/java/com/commonsware/android/eu4you4/EU4You.java)

In `SlidingPaneLayout` terminology, the pane is "open" if the *master* is shown on smaller screens, and the pane is "closed" if the *detail* is shown on smaller screens. If this feels a bit counter-intuitive to you, you are not alone in that regard.

By default, the `SlidingPaneLayout` is closed. So, if we want to start (on smaller screens) with the master pane shown, we need to call `openPane()`, as we do in `onCreate()`. Similarly:

- If we want to show the details when the user clicks on a country in the `CountriesFragment`, we need to call `closePane()` in `onCountrySelected()`
- If we want to show the master pane if the user presses BACK while viewing the detail pane, we need to override `onBackPressed()` and consume that event (calling `openPane()`), instead of performing the normal superclass behavior

What SlidingPaneLayout Looks Like

On a larger screen, the `SlidingPaneLayout` edition of the `EU4You` activity looks the same as the prior examples.

However, on a smaller screen, things look slightly different. Specifically:

- Our master perspective has a thin strip on the right, showing a peek of the detail fragment

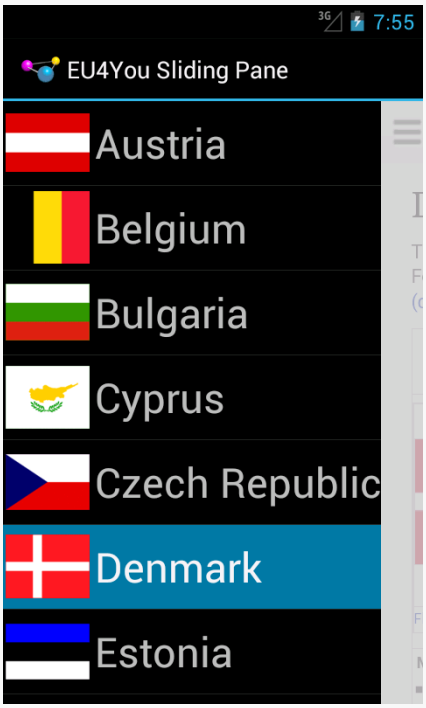

Figure 322: EU4YouSlidingPane, On a Phone Emulator, Showing Master

- The user can switch to the detail pane either by swiping open the detail pane or clicking on a country
- The user can switch back to the master pane either by swiping the detail pane back closed or by pressing the BACK button

Showing More Pages

`ViewPager` is a popular container in Android, as horizontal swiping is an increasingly popular navigational model, to move between peer pieces of content (e.g., swiping between contacts, swiping between book chapters). In some cases, when the `ViewPager` is on a larger screen, we simply want larger pages — a digital book reader, for example, would simply have a larger page in a bigger font for easier reading.

Sometimes, though, we might not be able to take advantage of the full space offered by the large screen, particularly when our `ViewPager` takes up the whole screen. In cases like this, it might be useful to allow `ViewPager`, in some cases, to show more than one page at a time. Each "page" is then designed to be roughly phone-sized, and we choose whether to show one, two, or perhaps more pages at a time based upon the available screen space.

Mechanically, allowing `ViewPager` to show more than one page is fairly easy, involving overriding one more method in our `PagerAdapter`: `getPageWidth()`. To see this in action, take a look at the `ViewPager/MultiView1` sample project.

Each page in this sample is simply a `TextView` widget, using the activity's style's "large appearance", centered inside a `LinearLayout`:

```
<LinearLayout xmlns:android="http://schemas.android.com/apk/res/android"
  android:layout_width="match_parent"
  android:layout_height="match_parent"
  android:gravity="center"
  android:orientation="vertical">

  <TextView
    android:id="@+id/text"
    android:layout_width="wrap_content"
    android:layout_height="wrap_content"
    android:textAppearance="?android:attr/textAppearanceLarge"/>

</LinearLayout>
```

(from ViewPager/MultiView1/app/src/main/res/layout/page.xml)

The activity, in `onCreate()`, gets our `ViewPager` from the `res/layout/activity_main.xml` resource, and sets its adapter to be a `SampleAdapter`:

```
  @Override
  public void onCreate(Bundle savedInstanceState) {
    super.onCreate(savedInstanceState);
    setContentView(R.layout.activity_main);

    pager=(ViewPager)findViewById(R.id.pager);
    pager.setAdapter(new SampleAdapter());
    pager.setOffscreenPageLimit(6);
  }
```

(from ViewPager/MultiView1/app/src/main/java/com/commonsware/android/mvp1/MainActivity.java)

In this case, `SampleAdapter` is not a `FragmentPagerAdapter`, nor a `FragmentStatePagerAdapter`. Instead, it is its own implementation of the `PagerAdapter` interface:

```
/*
 * Inspired by
 * https://gist.github.com/8cbe094bb7a783e37ad1
 */
private class SampleAdapter extends PagerAdapter {
  @Override
  public Object instantiateItem(ViewGroup container, int position) {
    View page=
        getLayoutInflater().inflate(R.layout.page, container, false);
    TextView tv=(TextView)page.findViewById(R.id.text);
    int blue=position * 25;

    final String msg=
        String.format(getString(R.string.item), position + 1);

    tv.setText(msg);
    tv.setOnClickListener(new OnClickListener() {
      @Override
      public void onClick(View v) {
        Toast.makeText(MainActivity.this, msg, Toast.LENGTH_LONG)
             .show();
      }
    });

    page.setBackgroundColor(Color.argb(255, 0, 0, blue));
    container.addView(page);

    return(page);
  }

  @Override
  public void destroyItem(ViewGroup container, int position,
                          Object object) {
    container.removeView((View)object);
  }

  @Override
  public int getCount() {
    return(9);
  }

  @Override
  public float getPageWidth(int position) {
```

```
    return(0.5f);
  }

  @Override
  public boolean isViewFromObject(View view, Object object) {
    return(view == object);
  }
}
```

(from ViewPager/MultiView1/app/src/main/java/com/commonsware/android/mvp1/MainActivity.java)

To create your own `PagerAdapter`, the big methods that you need to implement are:

- `instantiateItem()`, where you create the page itself and add it to the supplied container. In this case, we inflate the page, set the text of the `TextView` based on the supplied position, set the background color of the page itself to be a different shade of blue based on the position, set up a click listener to show a `Toast` when the `TextView` is tapped, and use that for our page. We return some object that identifies this page; in this case, we return the inflated `View` itself. A fragment-based `PagerAdapter` would probably return the fragment.
- `destroyItem()`, where we need to clean up a page that is being removed from the pager, where the page is identified by the `Object` that we had previously returned from `instantiateItem()`. In our case, we just remove it from the supplied container.
- `isViewFromObject()`, where we confirm whether some specific page in the pager (represented by a `View`) is indeed tied to a specific `Object` returned from `instantiateItem()`. In our case, since we return the `View` from `instantiateItem()`, we merely need to confirm that the two objects are indeed one and the same.
- `getCount()`, as with the built-in `PagerAdapter` implementations, to return how many total pages there are.

In our case, we also override `getPageWidth()`. This indicates, for a given position, how much horizontal space in the `ViewPager` should be given to this particular page. In principle, each page could have its own unique size. The return value is a `float`, from `0.0f` to `1.0f`, indicating what fraction of the pager's width goes to this page. In our case, we return `0.5f`, to have each page take up half the pager.

The result is that we have two pages visible at a time:

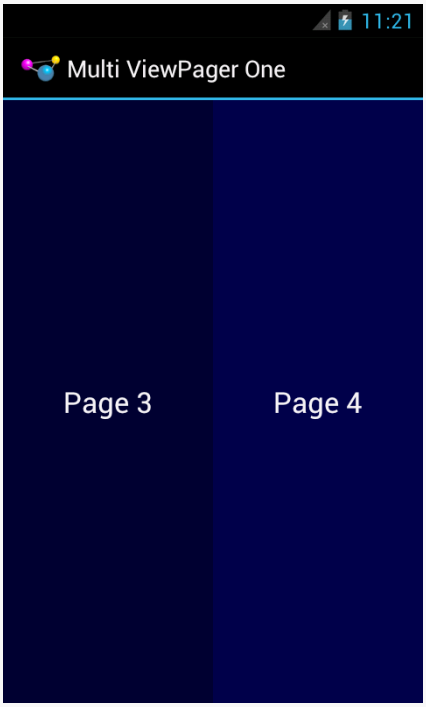

Figure 323: Two Pages in a ViewPager on Android 4.0.3

It is probably also a good idea to call `setOffscreenPageLimit()` on the `ViewPager`, as we did in `onCreate()`. By default (and at minimum), `ViewPager` will cache three pages: the one presently visible, and one on either side. However, if you are showing more than one at a time, you should bump the limit to be 3 times the number of simultaneous pages. For a page width of `0.5f` — meaning two pages at a time – you would want to call `setOffscreenPageLimit(6)`, to make sure that you had enough pages cached for both the current visible contents and one full swipe to either side.

`ViewPager` even handles "partial swipes" — a careful swipe can slide the right-hand page into the left-hand position and slide in a new right-hand page. And `ViewPager` stops when you run out of pages, so the last page will always be on the right, no matter how many pages at a time and how many total pages you happen to have.

The biggest downside to this approach is that it will not work well with the current crop of indicators. `PagerTitleStrip` and `PagerTabStrip` assume that there is a single selected page. While the indicator will adjust properly, the visual representation shows that the left-hand page is the one selected (e.g., the tab with the highlight), even though two or more pages are visible. You can probably overcome this with a custom indicator (e.g., highlight the selected tab and the one to its right).

Also note that this approach collides a bit with `setPageMargin()` on `ViewPager`. `setPageMargin()` indicates an amount of whitespace that should go in a gutter between pages. In principle, this would work great with showing multiple simultaneous pages in a `ViewPager`. However, `ViewPager` does not take the gutter into account when interpreting the `getPageWidth()` value. For example, suppose `getPageWidth()` returns `0.5f` and we `setPageMargin(20)`. On a 480-pixel-wide `ViewPager`, we will actually use 500 pixels: 240 for the left page, 240 for the right page, and 20 for the gutter. As a result, 20 pixels of our right-hand page are off the edge of the pager. Ideally, `ViewPager` would subtract out the page margin *before* applying the page width. One workaround is for you to derive the right `getPageWidth()` value based upon the `ViewPager` size and gutter yourself, rather than hard-coding a value. Or, build in your gutter into your page contents (e.g., using `android:layout_marginLeft` and `android:layout_marginRight`) and skip `setPageMargin()` entirely.

Columns or Pages

Another pattern — using pages for smaller screens and having the "pages" side-by-side in columns for larger screens — will be explored later in the book.

The Grid Pattern

Yet another approach for taking advantage of larger screen sizes is to always show a full-size master and a full-size detail — perhaps using different activities — but to use a grid rather than a list for the master. This works well when the data being shown in the grid can be represented as "cards", often dominated by some photo or other image.

The basic approach is to use fewer grid columns (e.g., 1 or 2) on smaller screen sizes and more grid columns (e.g., 3 or 4) on larger screen sizes. This way, the application flow is identical across screen sizes, yet the screen usage on larger screens is more effective. This is particularly true if you use on of the "staggered" grid widgets available from third parties, like Etsy's `AndroidStaggeredGrid` or Maurycy Wojtowicz's `StaggeredGridView`:

Figure 324: StaggeredGridView Demo (image courtesy of Maurycy Wojtowicz)

Fragment FAQs

Here are some other common questions about the use of fragments in support of large screen sizes:

Does *Everything* Have To Be In a Fragment?

In a word, no.

UI constructs that do not change based on screen size, configurations, and the like could simply be defined in the activity itself. For example, the activity can add items to the action bar that should be there regardless of what fragments are shown.

What If Fragments Are Not Right For Me?

While fragments are useful, they do not solve all problems. Few games will use fragments for the core of game play, for example. Applications with other forms of specialized user interfaces — painting apps, photo editors, etc. – may also be better served by avoiding fragments *for those specific activities* and doing something else.

That "something else" might start with custom layouts for the different sizes and orientations. At runtime, you can determine what you need either by inspecting what you got from the layout, or by using `Configuration` and `DisplayMetrics` objects to determine what the device capabilities are (e.g., screen size). The activity would then need to have its own code for handling whatever you want to do differently based on screen size (e.g., offering a larger painting canvas plus more on-screen tool palettes).

Do Fragments Work on TVs?

Much of the focus on "larger-screen devices" has been on tablets, because, as of the time of this writing, they are the most popular "larger-screen devices" in use. However, there are plenty of scenarios involving Android on TV to consider. A TV or other external display will present itself as a `-large` (720p) or `-xlarge` (1080p) screen. Fragments can certainly help with displaying a UI for a TV, but there are other design considerations to take into account, based upon the fact that the user sits much further from a TV than they do from a phone or tablet (so-called "10-foot user experience"). This is covered in greater detail later in the book.

Screen Size and Density Tactics

Even if we take the "tablet = several phones" design approach, the size of the "phone" will vary, depending on the size of the tablet. Plus, there are real actual *phones*, and those too vary in size. Hence, our fragments (or activities hosting their own UI directly) need to take into account micro fluctuations in size, as well as the macro ones.

Screen density is also something that affects us tactically. It is rare that an application will make wholesale UI changes based upon whether the screen is 160dpi or 240dpi or 320dpi or something else. However, changes in density can certainly impact the sizes of things, like images, that are intrinsically tied to pixel sizes. So, we need to take density into account as we are crafting our fragments to work well in a small range of sizes.

Dimensions and Units

As a unit of measure, the pixel (`px`) is a poor choice, because its size varies by density. Two phones might have very similar screen sizes but radically different densities. Anything specified in terms of pixels will be smaller on the higher-density device, and typically you would want them to be about the same size. For example, a

`Button` should not magically shrink for a ~4" phone just because the phone happens to have a much higher screen density than some other phone.

The best answer is to avoid specifying concrete sizes where possible. This is why you tend to see containers, and some widgets, use `match_parent` and `wrap_content` for their size — those automatically adjust based upon device characteristics.

Some places, though, you have to specify a more concrete size, such as with padding or margins. For these, you have two major groups of units of measure to work with:

- Those based upon pixels, but taking device characteristics into account. These include density-independent pixels (`dp` or `dip`), which try to size each `dp` to be about 1/160 of an inch. These also include scaled pixels (`sp`), which scales the size based upon the default font size on the device — `sp` is often used with `TextView` (and subclasses) for `android:textSize` attributes.
- Those based purely on physical units of measure: `mm` (millimeters), `in` (inches), and `pt` (points = 1/72 of an inch).

Any of those tends to be better than `px`. Which you choose will depend on which you and your graphics designer are more comfortable with.

If you find that there are cases where the dimensions you want to use vary more widely than the automatic calculations from these density-aware units of measure, you can use dimension resources. Create a `dimens.xml` file in `res/values/` and related resource sets, and put in there `<dimen>` elements that give a dimension a name and a size. In addition to perhaps making things a bit more DRY ("don't repeat yourself"), you can perhaps create different values of those dimensions for different screen sizes, densities, or other cases as needed.

Layouts and Stretching

Web designers need to deal with the fact that the user might resize their browser window. The approaches to deal with this are called "fluid" designs.

Similarly, Android developers need to create "fluid" layouts for fragments, rows in a `ListView`, and so on, to deal with similar minor fluctuations in size.

Each of "The Big Three" container classes has its approach for dealing with this:

- Use `android:layout_weight` with `LinearLayout` to allocate extra space

- Use `android:stretchColumns` and `android:shrinkColumns` with `TableLayout` to determine which columns should absorb extra space and which columns should be forcibly "shrunk" to yield space for other columns if we lack sufficient horizontal room
- Use appropriate rules on `RelativeLayout` to anchor widgets as needed to other widgets or the boundaries of the container, such that extra room flows naturally wherever the rules call for

Drawables That Resize

Images, particularly those used as backgrounds, will need to be resized to take everything into account:

- screen size and density
- size of the widget, and its contents, for which it serves as the background (e.g., amount of prose in a `TextView`)

Android supports what is known as the "nine-patch" PNG format, where resizing information is held in the PNG itself. This is typically used for things like rounded rectangles, to tell Android to stretch the straight portions of the rectangle but to not stretch the corners. Nine-patch PNG files will be examined in greater detail in a later chapter of this book.

The `ShapeDrawable` XML drawable resource uses an ever-so-tiny subset of SVG (Scalable Vector Graphics) to create a vector art definition of an image. Once again, this tends to be used for rectangles and rounded rectangles, particularly those with a gradient fill. Since Android interprets the vector art definition at runtime, it can create a smooth gradient, interpolating all intervening colors from start to finish. Stretching a PNG file — even a nine-patch PNG file — tends to result in "banding effects" on the gradients. `ShapeDrawable` is also covered later in this book.

Third-party libraries can also help. The `svg-android` project supplies a JAR that handles more SVG capabilities than does `ShapeDrawable`, though it too does not cover the entire SVG specification. Also, `WebView` has some ability to view SVG files on Android 3.0+.

Drawables By Density

Sometimes, though, there is no substitute for your traditional bitmap image. Icons and related artwork are not necessarily going to be stretched at runtime, but they are still dependent upon screen density. A 80x80 pixel image may look great on a

Samsung Galaxy Nexus or other `-xhdpi` device, coming in at around a quarter-inch on a side. However, when viewed on a `-mdpi` device, that same icon will be a half-inch on a side, which may be entirely too large.

The best answer is to create multiple renditions of the icon at different densities, putting each icon in the appropriate drawable resource directory (e.g., `res/drawable-mdpi`, `res/drawable-hdpi`). This is what Android Asset Studio did for us in the tutorials, creating launcher icons from some supplied artwork for all four densities. Even better is to create icons tailored for each density — rather than just reducing the pixel count, take steps to draw an icon that will still make sense to the user at the lower pixel count, exaggerating key design features and dropping other stuff off. Google's Kirill Grouchnikov has an excellent blog post on this aspect

However, Android will let you cheat.

If you supply only some densities, but your app runs on a device with a different density, Android will automatically resample your icons to try to generate one with the right density, to keep things the same size. On the plus side, this saves you work — perhaps you only ship an `-xhdpi` icon and let Android do the rest. And it can reduce your APK size by a bit. However, there are costs:

- This is a bit slower at runtime and consumes a bit more battery
- Android's resampling algorithm may not be as sophisticated as that of your preferred image editor (e.g., Photoshop)
- You cannot finesse the icon to look better than a simple resampling (e.g., drop off design elements that become unidentifiable)

Other Considerations

There are other things you should consider when designing your app to work on multiple screen sizes, beyond what is covered above.

Small-Screen Devices

It is easy to think of screen size issues as being "phones versus tablets". However, not only do tablets come in varying sizes (5" Samsung Galaxy Note to a bunch of 10.1" tablets), but phones come in varying sizes. Those that have less than a 3" diagonal screen size will be categorized as `-small` screen devices, and you can have different layouts for those.

Getting things to work on small screens is sometimes more difficult than moving from normal to larger screens, simply because you lack sufficient room. You can only shrink widgets so far before they become unreadable or "untappable". You may need to more aggressively use `ScrollView` to allow your widgets to have more room, but requiring the user to pan through your whole fragment's worth of UI. Or, you may need to divide your app into more fragments than you originally anticipated, and use more activities or other tricks to allow the user to navigate the fragments individually on small-screen devices, while stitching them together into larger blocks for larger phones.

Avoid Full-Screen Backgrounds

Android runs in lots of different resolutions.

Lots and lots of different resolutions.

Trying to create artwork for each and every resolution in use today will be tedious and fragile, the latter because new resolutions pop up every so often, ones you may not be aware of.

Hence, try to design your app to avoid some sort of full-screen background, where you are expecting the artwork to perfectly fit the screen. Either:

- Do not use a background, or
- Use a background, but one that is designed to be cropped to fit and will look good in its cropped state, or
- Use a background, but one that can naturally bleed into some solid fill to the edges (e.g., a starfield that simply lacks stars towards the edges), so you can "fill in" space around your background with that solid color to fill the screen, or
- Dynamically draw the background (e.g., a starfield where you place the stars yourself at runtime using 2D graphics APIs)

For most conventional apps, just using the background from your stock theme will typically suffice. This problem is much bigger for 2D games, which tend to rely upon backgrounds as a game surface.

Manifest Elements for Screen Sizes

There are two elements you can add to your manifest that impact how your application will behave with respect to screen sizes.

<compatible-screens> serves as an advertisement of your capabilities, to the Google Play Store and similar "markets". You can have a <compatible-screens> element with one or more child <screen> elements — each <screen> enumerates a combination of screen size and screen density that you support:

```
<compatible-screens>
    <!-- all possible normal size screens -->
    <screen android:screenSize="normal" android:screenDensity="ldpi" />
    <screen android:screenSize="normal" android:screenDensity="mdpi" />
    <screen android:screenSize="normal" android:screenDensity="hdpi" />
    <screen android:screenSize="normal" android:screenDensity="xhdpi" />
    <!-- all possible large size screens -->
    <screen android:screenSize="large" android:screenDensity="ldpi" />
    <screen android:screenSize="large" android:screenDensity="mdpi" />
    <screen android:screenSize="large" android:screenDensity="hdpi" />
    <screen android:screenSize="large" android:screenDensity="xhdpi" />
</compatible-screens>
```

The Google Play Store will filter your app, so it will not show up on devices that have screens that do not meet one of your <screen> elements. However, new densities show up every year or so, and devices running those densities will *not* be supported by your <compatible-screens> element unless you add the appropriate <screen> element for that density. For example, the above <compatible-screens> element does not cover tvdpi or xxhdpi devices. As a result, Google discourages the use of <compatible-screens>.

There is also a <supports-screens> element, as we saw when we set up our initial project in the tutorials. Here, you indicate what screen sizes you support, akin to <compatible-screens> (minus any density declarations). And, the Google Play Store will filter your app, so it will not show up on devices that have screens *smaller than what you support*.

So, for example, suppose that you have a <supports-screens> element like this:

```
<supports-screens android:smallScreens="false"
                  android:normalScreens="true"
                  android:largeScreens="true"
                  android:xlargeScreens="false"
/>
```

You will not show up in the Google Play Store for any -small screen devices. However, you *will* show up in the Google Play Store for any -xlarge screen devices — Android will merely apply some runtime logic to try to help your app run well on

such screens. So, while <compatible-screens> is purely a filter, <supports-screens> is a filter for smaller-than-supported screens, and a runtime "give me a hand!" flag for larger-than-supported screens.

Considering Newer Densities

-tvdpi — around 213dpi — was added for Android TV, and is the density used for 720p Android TV devices. However, Google *also* elected to use -tvdpi for the Nexus 7 tablet. However, not even Google bothered to create many -tvdpi-specific resources, allowing the OS to downsample from the -hdpi edition.

-xxhdpi was added in late 2012 and is for devices with a screen density around 480dpi. While Android can up-sample an -xhdpi image for -xxhdpi, the results may not be as crisp as you would like. Hence, you may wish to consider creating -xxhdpi as your "top tier" density, so other devices can downsample if needed. At the time of this writing, about 15% of Play Store-equipped Android devices are -xxhdpi.

-xxxhdpi is for devices with screens around 640dpi. At the time of this writing -xxxhdpi is not in significant use.

Tutorial #17 - Supporting Large Screens

So far, we have created a variety of fragments that are being used one at a time in a hosting activity: notes, help, and about. And, on smaller-screen devices, like phones, that is probably the best solution. But on devices like 10" tablets, it might be nice to be able to have some of those fragments take over a part of the main activity's space. For example, the user could be reading the chapter and reading the online help.

Hence, in this tutorial, we will arrange for the help and about fragments to be loaded into `EmPubLiteActivity` directly on tablets, while retaining our existing functionality for other devices.

This is a continuation of the work we did in the previous tutorial.

You can find the results of the previous tutorial and the results of this tutorial in the book's GitHub repository.

Step #1: Creating Our Layouts

The simplest way to both add a place for these other fragments and to determine when we should be using these other fragments in the main activity is to create new `layout` resource sets for larger-screen devices, with customized versions of `main.xml` to be used by `EmPubLiteActivity`.

Right-click over the `res/` directory in your app, then choose New > "Android Resource Directory" from the context menu. As before, this brings up the new resource directory dialog:

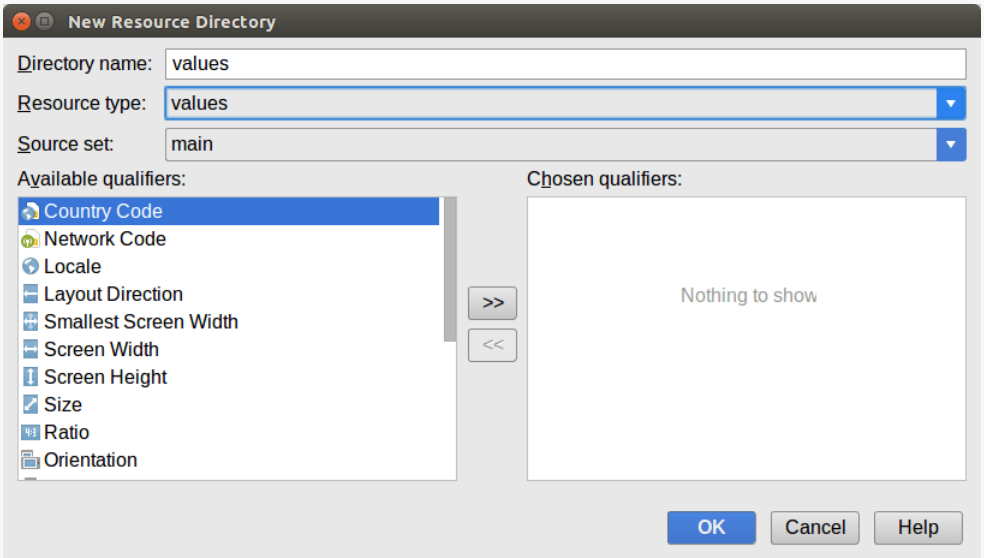

Figure 325: Android Studio New Resource Dialog, As Initially Opened

Choose "layout" from the "Resource type" drop-down. Then, click on "Screen Width" in the list of qualifiers on the left, and click the ">>" button to add that to the list on the right:

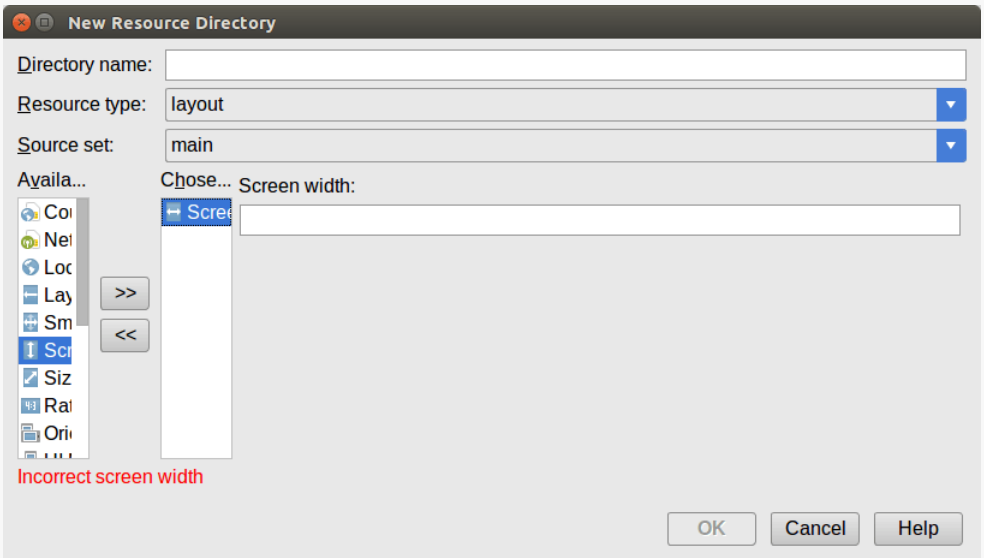

Figure 326: Android Studio New Resource Dialog, After Selecting "Screen Width"

In the "Screen width" field, fill in `880`:

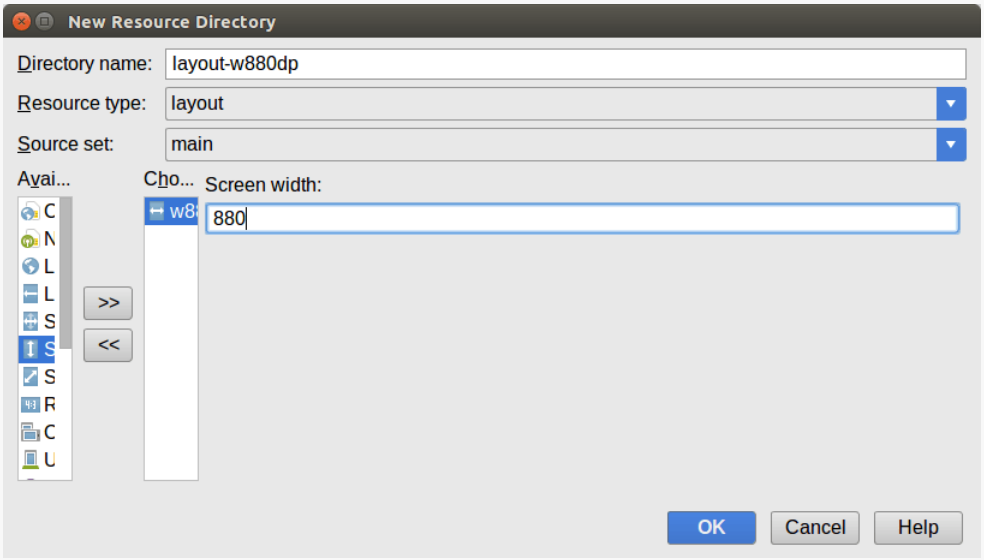

Figure 327: Android Studio New Resource Dialog, After Setting Screen Width

Click OK to create the directory. Repeat that process to create a `res/layout-h880dp/` directory, this time choosing "Screen Height" rather than "Screen Width".

Then, right-click over the `res/layout/main.xml` file and choose "Copy" from the context menu. After that, right-click over the new `res/layout-w880dp/` directory and choose "Paste" from the context menu. This brings up the copy dialog:

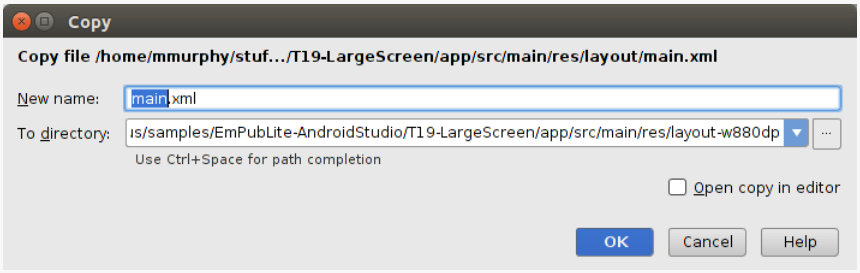

Figure 328: Android Studio Copy Dialog

Check the "Open copy in editor" checkbox and click OK. This will bring up the graphical layout editor on this copy of the `main` layout.

Unfortunately, what we want to do is not readily supported by Android Studio's edition of the drag-and-drop GUI builder. So, switch over to the XML for this layout, and replace it with:

```
<?xml version="1.0" encoding="utf-8"?>
<LinearLayout xmlns:android="http://schemas.android.com/apk/res/android"
  xmlns:app="http://schemas.android.com/apk/res-auto"
  android:layout_width="match_parent"
  android:layout_height="match_parent"
  android:orientation="horizontal">

  <LinearLayout
    android:layout_width="0dp"
    android:layout_height="match_parent"
    android:layout_weight="7"
    android:orientation="vertical">

    <io.karim.MaterialTabs
      android:id="@+id/tabs"
      android:layout_width="match_parent"
      android:layout_height="48dp"
      app:mtIndicatorColor="@color/colorAccent"
      app:mtSameWeightTabs="true" />

    <android.support.v4.view.ViewPager
      android:id="@+id/pager"
      android:layout_width="match_parent"
      android:layout_height="match_parent"></android.support.v4.view.ViewPager>
  </LinearLayout>

  <View
    android:id="@+id/divider"
    android:layout_width="2dp"
    android:layout_height="match_parent"
    android:background="#AA000000"
    android:visibility="gone" />

  <FrameLayout
    android:id="@+id/sidebar"
    android:layout_width="0dp"
    android:layout_height="match_parent" />
</LinearLayout>
```

(from EmPubLite-AndroidStudio/T17-LargeScreen/EmPubLite/app/src/main/res/layout-w880dp/main.xml)

Repeat the same process, copying `res/layout/main.xml` into the `res/layout-h880dp/` directory, and replacing the copy's contents with:

```
<?xml version="1.0" encoding="utf-8"?>
<LinearLayout xmlns:android="http://schemas.android.com/apk/res/android"
  xmlns:app="http://schemas.android.com/apk/res-auto"
  android:layout_width="match_parent"
```

```
  android:layout_height="match_parent"
  android:orientation="vertical">

  <LinearLayout
    android:layout_width="match_parent"
    android:layout_height="0dp"
    android:layout_weight="7"
    android:orientation="vertical">

    <io.karim.MaterialTabs
      android:id="@+id/tabs"
      android:layout_width="match_parent"
      android:layout_height="48dp"
      app:mtIndicatorColor="@color/colorAccent"
      app:mtSameWeightTabs="true" />

    <android.support.v4.view.ViewPager
      android:id="@+id/pager"
      android:layout_width="match_parent"
      android:layout_height="match_parent"></android.support.v4.view.ViewPager>
  </LinearLayout>

  <View
    android:id="@+id/divider"
    android:layout_width="match_parent"
    android:layout_height="2dp"
    android:background="#AA000000"
    android:visibility="gone" />

  <FrameLayout
    android:id="@+id/sidebar"
    android:layout_width="match_parent"
    android:layout_height="0dp"></FrameLayout>
</LinearLayout>
```

(from EmPubLite-AndroidStudio/T17-LargeScreen/EmPubLite/app/src/main/res/layout-h880dp/main.xml)

Step #2: Loading Our Sidebar Widgets

Now that we added the divider widget and sidebar container to (some of) our layouts, we need to access those widgets at runtime.

So, in `EmPubLiteActivity`, add data members for them:

```
  private View sidebar=null;
  private View divider=null;
```

(from EmPubLite-AndroidStudio/T17-LargeScreen/EmPubLite/app/src/main/java/com/commonsware/empublite/EmPubLiteActivity.java)

Then, in `onCreate()` of `EmPubLiteActivity`, initialize those data members, sometime after the call to `setContentView()`:

```
    sidebar=findViewById(R.id.sidebar);
    divider=findViewById(R.id.divider);
```

(from EmPubLite-AndroidStudio/T17-LargeScreen/EmPubLite/app/src/main/java/com/commonsware/empublite/EmPubLiteActivity.java)

Step #3: Opening the Sidebar

A real production-grade app would use animated effects to hide and show our sidebar. However, we have not yet covered animations in this book, so we will simply:

- Cause the divider to become visible
- Adjust the `android:layout_weight` of our sidebar to be `3` instead of `0`, giving it ~30% of the screen (with the original `RelativeLayout` getting 70%, courtesy of its `android:layout_weight="7"`)

With that in mind, add the following implementation of an `openSidebar()` method to `EmPubLiteActivity`:

```
  private void openSidebar() {
    LinearLayout.LayoutParams p=
      (LinearLayout.LayoutParams)sidebar.getLayoutParams();
    if (p.weight == 0) {
      p.weight=3;
      sidebar.setLayoutParams(p);
    }

    divider.setVisibility(View.VISIBLE);
  }
```

(from EmPubLite-AndroidStudio/T17-LargeScreen/EmPubLite/app/src/main/java/com/commonsware/empublite/EmPubLiteActivity.java)

Here, we:

- Get the existing `LinearLayout.LayoutParams` from the sidebar

- If it is still `0` (meaning the sidebar has not been opened), assign it a weight of `3`, update the layout via `setLayoutParams()`, and toggle the visibility of the divider

Step #4: Loading Content Into the Sidebar

Now that we can get our sidebar to appear, we need to load content into it... but only if we have the sidebar. If `EmPubLiteActivity` loads a layout that does not have the sidebar, we need to stick with our existing logic that starts up an activity to display the content.

With that in mind, add data members to `EmPubLiteActivity` to hold onto our help and about fragments:

```
private SimpleContentFragment help=null;
private SimpleContentFragment about=null;
```

(from EmPubLite-AndroidStudio/T17-LargeScreen/EmPubLite/app/src/main/java/com/commonsware/empublite/EmPubLiteActivity.java)

Also add a pair of static data members that will be used as tags for identifying these fragments in our `FragmentManager`:

```
private static final String HELP="help";
private static final String ABOUT="about";
```

(from EmPubLite-AndroidStudio/T17-LargeScreen/EmPubLite/app/src/main/java/com/commonsware/empublite/EmPubLiteActivity.java)

Also add a pair of static data members that will hold the paths to our help and about assets, since we will be referring to them from more than one place when we are done:

```
private static final String FILE_HELP=
  "file:///android_asset/misc/help.html";
private static final String FILE_ABOUT=
  "file:///android_asset/misc/about.html";
```

(from EmPubLite-AndroidStudio/T17-LargeScreen/EmPubLite/app/src/main/java/com/commonsware/empublite/EmPubLiteActivity.java)

In `onCreate()` of `EmPubLiteActivity`, initialize the fragments from the `FragmentManager`:

```
    help=(SimpleContentFragment)getFragmentManager().findFragmentByTag(HELP);
    about=
      (SimpleContentFragment)getFragmentManager().findFragmentByTag(ABOUT);
```

(from EmPubLite-AndroidStudio/T17-LargeScreen/EmPubLite/app/src/main/java/com/commonsware/empublite/EmPubLiteActivity.java)

The net result is that *if* we are returning from a configuration change, we will have our fragments, otherwise we will not at this point.

Next, add the following methods to `EmPubLiteActivity`:

```
private void showAbout() {
  if (sidebar!=null) {
    openSidebar();

    if (about==null) {
      about=SimpleContentFragment.newInstance(FILE_ABOUT);
    }

    getFragmentManager().beginTransaction().addToBackStack(null)
      .replace(R.id.sidebar, about, ABOUT).commit();
  }
  else {
    Intent i=new Intent(this, SimpleContentActivity.class);

    i.putExtra(SimpleContentActivity.EXTRA_FILE, FILE_ABOUT);
    startActivity(i);
  }
}

private void showHelp() {
  if (sidebar!=null) {
    openSidebar();

    if (help==null) {
      help=SimpleContentFragment.newInstance(FILE_HELP);
    }

    getFragmentManager().beginTransaction().addToBackStack(null)
      .replace(R.id.sidebar, help, HELP).commit();
  }
  else {
    Intent i=new Intent(this, SimpleContentActivity.class);

    i.putExtra(SimpleContentActivity.EXTRA_FILE, FILE_HELP);
    startActivity(i);
```

```
    }
  }
```

(from EmPubLite-AndroidStudio/T17-LargeScreen/EmPubLite/app/src/main/java/com/commonsware/empublite/EmPubLiteActivity.java)

Both of these methods follow the same basic recipe:

- Check to see if `sidebar` is `null`, to see if we have a sidebar or not
- If we have a sidebar, call `openSidebar()` to ensure the user can see the sidebar, create our `Fragment` if we do not already have it, and use a `FragmentTransaction` to replace whatever was in the sidebar with the new `Fragment`
- If we do not have the sidebar, launch an activity with an appropriately-configured `Intent`

Note a couple of things with our `FragmentTransaction` objects:

- We use `addToBackStack(null)`, so if the user presses BACK, Android will reverse this transaction
- We use `replace()` instead of `add()`, as there may already be a fragment in the sidebar (`replace()` will behave the same as `add()` for an empty sidebar)

Then, in the `onOptionsItemSelected()` of `EmPubLiteActivity`, replace the `about`, and `help` `case` blocks to use the newly-added methods, replacing their existing implementations:

```
      case R.id.about:
        showAbout();

        return(true);

      case R.id.help:
        showHelp();

        return(true);
```

(from EmPubLite-AndroidStudio/T17-LargeScreen/EmPubLite/app/src/main/java/com/commonsware/empublite/EmPubLiteActivity.java)

Step #5: Removing Content From the Sidebar

While `addToBackStack(null)` will allow Android to automatically remove fragments as the user presses BACK, that will not cause our sidebar to magically close. Rather, we need to do that ourselves.

The easiest way to track this is to track the state of the "back stack". So, add `implements FragmentManager.OnBackStackChangedListener` to the declaration of `EmPubLiteActivity`, and in `onCreate()` of `EmPubLiteActivity`, add the following line, sometime after you initialized the `sidebar` and `divider` data members:

```
    getFragmentManager().addOnBackStackChangedListener(this);
```

(from EmPubLite-AndroidStudio/T17-LargeScreen/EmPubLite/app/src/main/java/com/commonsware/empublite/EmPubLiteActivity.java)

This statement registers our activity as receiving events related to changes in the state of the back stack.

To make this compile, we need to implement `onBackStackChanged()` in `EmPubLiteActivity`:

```
  @Override
  public void onBackStackChanged() {
    if (getFragmentManager().getBackStackEntryCount() == 0) {
      LinearLayout.LayoutParams p=
        (LinearLayout.LayoutParams)sidebar.getLayoutParams();
      if (p.weight > 0) {
        p.weight=0;
        sidebar.setLayoutParams(p);
        divider.setVisibility(View.GONE);
      }
    }
  }
```

(from EmPubLite-AndroidStudio/T17-LargeScreen/EmPubLite/app/src/main/java/com/commonsware/empublite/EmPubLiteActivity.java)

Here, if our back stack is empty, we reverse the steps from `openSidebar()` and close it back up again, hiding the divider and setting the sidebar's weight to `0`.

The complete revised `EmPubLiteActivity` should now look something like:

```
package com.commonsware.empublite;
```

```
import android.app.Activity;
import android.app.FragmentManager;
import android.content.Intent;
import android.content.SharedPreferences;
import android.os.Bundle;
import android.os.StrictMode;
import android.support.v4.view.ViewPager;
import android.view.Menu;
import android.view.MenuItem;
import android.view.View;
import android.widget.LinearLayout;
import org.greenrobot.eventbus.EventBus;
import org.greenrobot.eventbus.Subscribe;
import org.greenrobot.eventbus.ThreadMode;
import io.karim.MaterialTabs;

public class EmPubLiteActivity extends Activity

  }
}
```

(from EmPubLite-AndroidStudio/T17-LargeScreen/EmPubLite/app/src/main/java/com/commonsware/empublite/EmPubLiteActivity.java)

At this point, if you build the project and run it on a sufficiently-large device or emulator, and you choose to view the help or about pages, you will see the sidebar appear, whether in portrait or landscape.

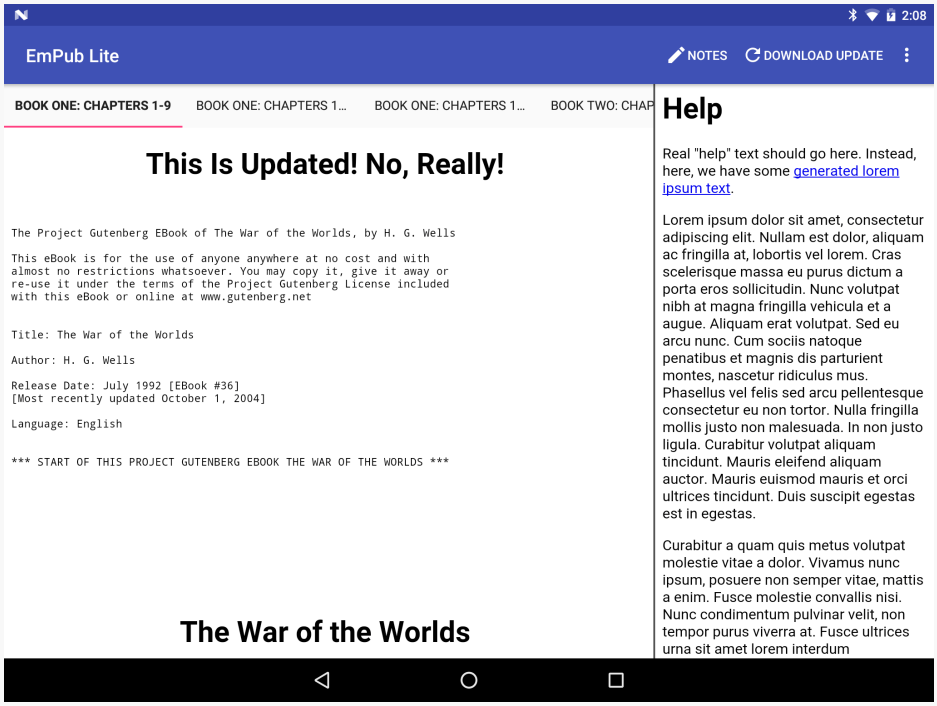

Figure 329: EmPubLite, on a Tablet-Sized Emulator, With Help

Note that a tablet emulator usually will only run acceptably fast if you are using the x86 emulator images.

Backwards Compatibility Strategies and Tactics

Android is an ever-moving target, averaging about 2.5 API level increments per year. The Android Developer site maintains a chart and table showing the most recent breakdown of OS versions making requests of the Play Store.

Most devices tend to be clustered around 1-3 minor releases. However, these are never the most recent release, which takes time to percolate through the device manufacturers and carriers and onto devices, whether those are new sales or upgrades to existing devices.

Some developers panic when they realize this.

Panic is understandable, if not necessary. This is a well-understood problem, that occurs frequently within software development — ask any Windows developer who had to simultaneously support everything from Windows 98 to Windows XP, or Windows XP through Windows 8.1. Moreover, there are many things in Android designed to make this problem as small as possible. What you need are the strategies and tactics to make it all work out.

Think Forwards, Not Backwards

Android itself tries very hard to maintain backwards compatibility. While each new Android release adds many classes and methods, relatively few are marked as deprecated, and almost none are outright eliminated. And, in Android, "deprecated" means "there's probably a better solution for what you are trying to accomplish, though we will maintain this option for you as long as we can".

Despite this, many developers aim purely for the lowest common denominator. Aiming to support older releases is noble. Ignoring what has happened since those releases is stupid, if you are trying to distribute your app to the public via the Play Store or similar mass-distribution means.

Why? You want your app to be distinctive, not decomposing.

For example, as we saw in the chapter on the action bar, adding one line to the manifest (`android:targetSdkVersion="11"`) gives you the action bar, the holographic widget set (e.g., `Theme.Holo`), the new style of options menu, and so on. Those dead-set on avoiding things newer than Android 2.1 would not use this attribute. As a result, on Android 3.0+ devices, their apps will tend to look old. Some will not, due to other techniques they are employing (e.g., running games in a full-screen mode), but many will.

You might think that this would not matter. After all, how many people in 2011 were even using Android 3.x? 5%?

However, those in position to trumpet your application — Android enthusiast bloggers chief among them — will tend to run newer equipment. Their opinion matters, if you are trying to have their opinion sway others relative to your app. Hence, if you look out-of-touch to them, they may be less inclined to provide glowing recommendations of your app to their readers.

Besides, not everything added to newer versions of Android is pure "eye candy". It is entirely possible that features in the newer Android releases might help make your app stand out from the competition, whether it is making greater use of NFC or offering tighter integration to the stock Calendar application or whatever. By taking an "old features only" approach, you leave off these areas for improvement.

And, to top it off, the world moves faster than you think. It takes about a year for a release to go from release to majority status (or be already on the downslope towards oblivion, passed over by something newer still). You need to be careful that the decisions you make today do not doom you tomorrow. If you focus on "old features only", how much rework will it take you to catch up in six months, or a year?

Hence, this book advocates an approach that differs from that taken by many: aim high. Decide what features you want to use, whether those features are from older releases or the latest-and-greatest release. Then, write your app using those features, and take steps to ensure that everything still works reasonably well (if not as full-featured) on older devices. This too is a well-trodden path, used by Web developers

for ages (e.g., support sexy stuff in Firefox and Safari, while still gracefully degrading for IE6). And the techniques that those Web developers use have their analogous techniques within the Android world.

Aim Where You Are Going

One thing to bear in mind is that the OS distribution chart and table shown above is based on devices contacting the Play Store. Hence, this is only directly relevant if you are actually distributing through the Play Store.

If you are distributing through the Amazon AppStore, or to device-specific outlets (e.g., BlackBerry World), you will need to take into account what sorts of devices are using those means of distribution.

If you are specifically targeting certain non-Play Store devices, like the Kindle Fire, you will need to take into account what versions of Android they run.

If you are building an app to be distributed by a device manufacturer on a specific device, you need to know what Android version will (initially) be on that device and focus on it.

If you are distributing your app to employees of a firm, members of an organization, or the like, you need to determine if there is some specific subset of devices that they use, and aim accordingly. For example, some enterprises might distribute Android devices to their employees, in which case apps for that enterprise should run on those devices, not necessarily others.

A Target-Rich Environment

There are a few places in your application where you will need to specify Android API levels of relevance to your code.

The most important one is the `android:minSdkVersion` attribute, as discussed early in this book. You need to set this to the oldest version of Android you are willing to support, so you will not be installed on devices older than that.

There is also `android:targetSdkVersion`, mentioned in passing earlier in this chapter. In the abstract, this attribute tells Android "this is the version of Android I was thinking of when I wrote the code". Android can use this information to help both backwards and forwards compatibility. Historically, this was under-utilized.

However, with API Level 11 and API Level 14, `android:targetSdkVersion` took on greater importance. Specifying 11 or higher gives you the action bar and all the rest of the look-and-feel introduced in the Honeycomb release. Specifying 14 or higher will give you some new features added in Ice Cream Sandwich, such as automatic whitespace between your app widgets and other things on the user's home screen. In general, use a particular `android:targetSdkVersion` when instructions tell you to.

The third place — and perhaps the one that confuses developers the most – is the build target. This shows up as `compileSdkVersion` in `build.gradle` for Android Studio and Gradle users.

Part of the confusion is the multiple uses of the term "target". The build target has nothing to do with `android:targetSdkVersion`. Nor is it strictly tied to what devices you are targeting.

Rather, it is a very literal term: it is the target **of the build**. It indicates:

- What version of the Android class library you wish to compile against, dictating what classes and methods you will be able to refer to directly
- What rules to apply when interpreting resources and the manifest, to complain about things that are not recognized

The net is that you set your build target to be the lowest API level that has everything you are using directly.

Lint: It's Not Just For Belly Buttons

In the old days, the only way to find out that you were using a newer class or method than what was in your `minSdkVersion` would be to set your build target to be the same as your `minSdkVersion`. That way, any attempt to use something newer than your minimum would be greeted with compile errors. This works, but at a high cost: it makes *intentionally* using newer capabilities very painful, forcing you to use reflection to access them.

Nowadays, this is no longer needed, thanks to Lint.

Lint is part of the standard build process, adding new errors and warnings for things that are syntactically valid but probably not the right answer. In particular, Lint will tell you if you are using classes or methods that are newer than your `minSdkVersion`, *even if they are valid for your build target*.

Hence, the targeting strategy nowadays is:

- Set your `minSdkVersion` to be the oldest version that you are willing to support
- Set your build target to be the version of Android that has all of the classes and methods you intend to use, allowing Lint to point out places where you need to pay attention to what sort of device you are running on (more on this later)
- Set your `targetSdkVersion` to be something relatively recent, unless you have specific reasons to use some specific version

A Little Help From Your Friends

The simplest way to use a feature yet support devices that lack the feature is to use a compatibility library that enables the feature for more devices. The Android Support package is one such compatibility library, though it also offers other classes as well.

With a compatibility library, the API for using the library is nearly identical to using the native Android capability, mostly involving slightly different package names (e.g., `android.support.v4.app.Fragment` instead of `android.app.Fragment`).

So, if there is something new that you want to use on older devices, and the new feature is not obviously tied to hardware, see if there is a "backport" of the feature available to you. Examples include backports of:

- `CalendarView` (https://github.com/SimonVT/android-calendarview)
- `Switch` (https://github.com/BoD/android-switch-backport)
- `DatePicker` (https://github.com/SimonVT/android-datepicker)
- `NumberPicker` (https://github.com/SimonVT/android-numberpicker)
- `TimePicker` (https://github.com/SimonVT/android-timepicker)

Avoid the New on the Old

If the goal is to support new capabilities on new devices, while not losing support for older devices, that implies we have the ability to determine what devices are newer and what devices are older. There are a few techniques for doing this, involving Java and resources.

Java

If you wish to conditionally execute some lines of code based on what version of Android the device is running, you can check the value of `Build.VERSION`, referring to the `android.os.Build` class. For example:

```
if (Build.VERSION.SDK_INT >= Build.VERSION_CODES.GINGERBREAD) {
  // do something only on API Level 9 and higher
}
```

Any device running an older version of Android will skip the statements inside this version guard and therefore will not execute.

That technique is sufficient for Android 2.0 and higher devices. If you are still supporting Android 1.x devices, the story gets a bit more complicated, and that will be discussed later in the book.

If you decide that you want your build target to match your `minSdkVersion` level — as some developers elect to do — your approach will differ. Rather than *blocking* some statements from being executed on *old* devices, you will *enable* some statements to be executed on *new* devices, where those statements use Java reflection (e.g., `Class.forName()`) to reference things that are newer than what your build target supports. Since using reflection is extremely tedious in Java, it is usually simpler to have your build target reflect the classes and methods you are actually using.

@TargetAPI

One problem with this technique is that your IDE will grumble at you, saying that you are using classes and methods not available on the API level you set for your `minSdkVersion`. To quiet down these Lint messages, you can use the `@TargetAPI` annotation.

For example, earlier in the book, we saw code like this:

```
@TargetApi(Build.VERSION_CODES.HONEYCOMB)
static public <T> void executeAsyncTask(AsyncTask<T, ?, ?> task, T... params) {
  if (Build.VERSION.SDK_INT >= Build.VERSION_CODES.HONEYCOMB) {
    task.executeOnExecutor(AsyncTask.THREAD_POOL_EXECUTOR, params);
  }
  else {
    task.execute(params);
```

```
  }
}
```

This utility method executes an `AsyncTask` using a multi-threaded thread pool. That is the default behavior of `execute()` on API Level 10 and below. On higher versions of Android, we can explicitly opt into the multi-threaded thread pool by using `executeOnExecutor()`, but that method does not exist prior to API Level 11. Hence, we check our API level at runtime via `Build.VERSION.SDK_INT`, see if we are on `HONEYCOMB` or higher, and branch accordingly. However, for a project with a `minSdkVersion` of 10 or below, Lint will still complain — Lint is just not sophisticated enough to realize that we are correctly handling newer API levels. The `@TargetApi(Build.VERSION_CODES.HONEYCOMB)` annotation tells Lint that we have indeed confirmed that we are "doing the right thing", at least through API Level 11.

However, by using `@TargetApi(Build.VERSION_CODES.HONEYCOMB)`, we are implicitly saying that we have *not* checked to see if we are doing things properly for higher versions of Android. So long as all the classes, methods, and such that we reference in this `executeAsyncTask()` method are available in API Level 11, we are fine. If we change the implementation to reference something from, say, API Level 14, now Lint will start complaining again. **This is what we want**, so we are alerted to the problem and can fix it. Hence, *only* set the `@TargetApi()` annotation to the API level that are you explicitly handling. Do not just set it to some arbitrarily high level (or, worse, use `@SuppressWarning` to try to get Lint to shut up entirely).

Resources

The aforementioned version guards only work for Java code. Sometimes, you will want to have different resources for different versions of Android. For example, you might want to make a custom style that inherits from `Theme.Holo` for Android 3.0 and higher. Since `Theme.Holo` does not exist on earlier versions of Android, trying to use a style that inherits from it will fail miserably on, say, an Android 2.2 device.

To handle this scenario, use the `-vNN` suffix to have two resource sets. One (e.g., `res/values-v11/`) would be restricted to certain Android versions and higher (e.g., API Level 11 and higher). The default resource set (e.g., `res/values/`) would be valid for any device. However, since Android chooses more specific matches first, an Ice Cream Sandwich phone would go with the resources containing the `-v11` suffix. So, in the `-v11` resource directories, you put the resources you want used on API Level 11 and higher, and put the backwards-compatible ones in the set without the suffix. This works for Android 2.0 and higher. You can also use `-v3` for resources that *only*

will be used on Android 1.5 (and no higher) or `-v4` for resources that *only* will be used on Android 1.6.

Components

One variation on the above trick allows you to conditionally enable or disable components, based on API level.

Every `<activity>`, `<receiver>`, or `<service>` in the manifest can support an `android:enabled` attribute. A disabled component (`android:enabled="false"`) cannot be started by anyone, including you.

We have already seen string resources be used in the manifest, for things like `android:label` attributes. Boolean values can also be created as resources. By convention, they are stored in a `bools.xml` file in `res/values/` or related resource sets. Just as `<string>` elements provide the definition of a string resource, `<bool>` elements provide the definition of a boolean resource. Just give the boolean resource a name and a value:

```
<?xml version="1.0" encoding="utf-8"?>
<resources>
    <bool name="on_honeycomb">false</bool>
</resources>
```

The above example has a boolean resource, named `on_honeycomb`, with a value of `false`. That would typically reside in `res/values/bools.xml`. However, you might also have a `res/values-v11/bools.xml` file, where you set `on_honeycomb` to `true`.

Now, you can use `@bool/on_honeycomb` in `android:enabled` to conditionally enable a component for API Level 11 or higher, leaving it disabled for older devices.

This can be a useful trick in cases where you might need multiple separate implementations of a component, based on API level. For example, later in the book we will examine app widgets — those interactive elements users can add to their home screens. App widgets have limited user interfaces, but API Level 11 added a few new capabilities that previously were unavailable, such as the ability to use `ListView`. However, the code for a `ListView`-backed app widget may be substantially different than for a replacement app widget that works on older devices. And, if you leave the `ListView` app widget enabled in the manifest, the user might try choosing it and crashing. So, you would only enable the `ListView` app widget on API Level 11 or higher, using the boolean resource trick.

Testing

Of course, you will want to make sure your app really does work on older devices as well as newer ones.

At build time, one trick to use periodically is to change your build target to match your `minSdkVersion`, then see where the compiler complains. If everything is known (e.g., resource attributes that will be ignored on older versions) or protected (e.g., Java statements inside a version guard `if` statement), then you are OK. If, however, you see complaints about something you forgot was only in newer Android releases, you can take steps to fix things.

You will also want to think about Android versions when it comes to testing, a topic that will be covered later in this book.

Keeping Track of Changes

Each Android SDK release is accompanied by API release notes, such as this set for Android 4.4/API Level 19.

Similarly, each Android SDK release is accompanied by its "API Differences Report", a roster of each added, removed, or modified class or method. For example, this API Differences Report points out the changes between API Level 18 and API Level 19.

Other changes are called out in the JavaDocs for `Build.VERSION_CODES`, with particular emphasis on what happens when you set a specific API level as your `android:targetSdkVersion`. Note that this roster is not complete, but may mention some things not mentioned in the other locations.

Each class, method, and field in the JavaDocs has a notation as to what API level that particular item was added. Class API levels appear towards the top of the page; method and field API levels appear on the right side of the gray bar containing the method signature or field declaration. Also, in the JavaDocs "Android APIs" column on the left, there is a drop-down that allows you to filter the contents based upon API level.

System Services

One of the problems that we have in Android app development is the overloading of terms. We have already seen how "layouts" sometimes refer to layout resources and sometimes refer to container classes like `LinearLayout`.

Another example comes in the name "service". This was already used in a few places in Java (e.g., `ExecutorService`). Android then used it for one of our four app components. Android *also* uses "service" as part of the term "system service"... where system services have little to do with Java services or Android services.

What is a System Service?

System services are "manager"-type classes that you get by calling `getSystemService()` on some `Context`, such as an `Activity` or `Service`. Usually, system services are tied to lower-level device functionality, like telephony. However, not all low-level device functionality is exposed by means of system services; some have separate APIs implemented by other sorts of "manager" classes.

There are two flavors of `getSystemService()`. The one that you are likely to use is the one that takes a `String` parameter that is the name of the system service that you want. You get back a generic `Object`, which you then have to downcast to the specific type of system service that you are trying to use:

```
AlarmManager mgr=(AlarmManager)someContext.getSystemService(Context.ALARM_SERVICE);
```

API Level 23 finally added a type-safe version of `getSystemService()`. You pass in the Java class object for the system service and get an instance of that class back:

```
AlarmManager mgr=someContext.getSystemService(AlarmManager.class);
```

However, until your `minSdkVersion` rises to 23 or higher, you will not be able to use that version of `getSystemService()` on `Context` on older devices.

Alas, there is no backport of `getSystemService()` on `ContextCompat` from the Android Support library.

What System Services Are There?

There are many system services, with new ones coming every Android version release or two. Here are the major ones as of Android 6.0, with links to chapters that focus on them (where available):

- `AccessibilityManager`, for being notified of key system events (e.g., activities starting) that might be relayed to users via haptic feedback, audio prompts, or other non-visual cues
- `AccountManager`, for working with Android's system of user accounts and synchronization
- `ActivityManager`, for getting more information about what processes and components are presently running on the device
- `AlarmManager`, for scheduled tasks (a.k.a., "cron jobs"), covered elsewhere in this book
- `AppOpsManager`, for "tracking application operations on the device"
- `AppWidgetManager`, for creating or hosting app widgets
- `AudioManager`, for managing audio stream volumes, audio ducking, and other system-wide audio affordances
- `BatteryManager`, for finding out about the state of the battery
- `BluetoothManager`, for exposing or connecting to Bluetooth services
- `ClipboardManager`, for working with the device clipboard, covered elsewhere in this book
- `ConnectivityManager`, for a high-level look as to what sort of network the device is connected to for data (e.g., WiFi, 3G)
- `ConsumerIrManager`, for creating "IR blaster" or other IR-sending apps, on hardware that has an IR transmitter
- `DevicePolicyManager`, for accessing device administration capabilities, such as wiping the device
- `DisplayManager`, for working with external displays, covered elsewhere in this book
- `DownloadManager`, for downloading large files on behalf of the user, covered in elsewhere in the book

- `DropBoxManager`, for maintaining your own ring buffers of logging information akin to Logcat
- `FingerprintManager`, for working with fingerprint readers on Android 6.0+ devices
- `InputMethodManager`, for working with input method editors
- `InputManager`, for identifying external sources of input, such as keyboards and trackpads
- `JobScheduler`, for scheduling periodic background work, covered elsewhere in the book
- `KeyguardManager`, for locking and unlocking the keyguard, where possible
- `LauncherApps`, for identifying launchable apps on the device (e.g., for home screen launchers), taking into account device policies
- `LayoutInflater`, for inflating layout XML files into Views, as you saw earlier in the book
- `LocationManager`, for determining the device's location (e.g., GPS), covered in the chapter on location tracking
- `MediaProjectionManager`, for capturing screenshots and screencasts
- `MediaRouter`, for working with external speakers and displays
- `MediaSessionManager`, for teaching Android about media that you are playing back
- `MidiManager`, for playing MIDI audio
- `NetworkStatsManager`, "for querying network usage stats"
- `NfcManager`, for reading NFC tags or pushing NFC content
- `NotificationManager`, for putting icons in the status bar and otherwise alerting users to things that have occurred asynchronously, covered in the chapter on `Notification`
- `NsdManager`, for network service discovery operations
- `PowerManager`, for obtaining `WakeLock` objects and such, covered elsewhere in this book
- `PrintManager`, for printing from Android
- `RestrictionsManager`, for identifying and working with restricted operations
- `SearchManager`, for interacting with the global search system
- `SensorManager`, for accessing data about sensors, such as the accelerometer, covered elsewhere in this book
- `StorageManager`, for working with expanded payloads (OBBs) delivered as part of your app's installation from the Play Store
- `SubscriptionManager`, for dealing with data roaming and other telephony subscription rules
- `TelecomManager`, for dealing with incoming and outgoing phone calls

- `TelephonyManager`, for finding out about the state of the phone and related data (e.g., SIM card details)
- `TextServicesManager`, for working with spelling checkers and other "text services"
- `TvInputManager`, for Android-powered televisions, to find out about TV inputs
- `UiModeManager`, for dealing with different "UI modes", such as being docked in a car or desk dock
- `UsageStatsManager`, "for querying device usage stats"
- `UsbManager`, for working directly with accessories and hosts over USB
- `UserManager`, for working with multiple user accounts on a compatible device (Android 4.2+ tablets, Android 5.0+ phones)
- `Vibrator`, for shaking the phone (e.g., haptic feedback)
- `WallpaperService`, for working with the device wallpaper
- `WifiManager`, for getting more details about the active or available WiFi networks
- `WifiP2pManager`, for setting up and communicating over WiFi peer-to-peer (P2P) networks
- `WindowManager`, mostly for accessing details about the default display for the device

Google Play Services

A term that you will encounter a fair bit as an Android developer is “Google Play Services”, or “Play Services” for short. This is your gateway into a series of proprietary capabilities that Google has layered on top of Android. Many of these capabilities are tied to Google’s servers and services, such as ads and Google Drive.

However, these capabilities, while usually free from monetary cost to the developer, are not free from problems or controversy.

What Is Google Play Services?

Google Play Services is a “kitchen sink” term, encompassing a wide range of things from the standpoint of developers and users alike.

…From the Standpoint of Developers?

The Play Services SDK allows you to integrate your Android app with a number of Google proprietary services, from leaderboard management for games to interacting with Chromecast devices. Many, but not all, of these services are tied to Google servers. Many, but not all, of these services will require some sort of API key as a result.

The SDK comes in the form of an Android library project that you link into your app, giving you access to classes and methods that let you add maps, or payment options, or push message receipt into your Android apps.

Note that while the name “Play Services” contains the word “services”, Play Services is merely an API, one that does not directly have anything to do with services or system services.

…From the Standpoint of Users of Google Play Devices?

In Western countries, the common perception is that all Android devices are part of the Google Play world. These devices will have the Play Services Framework pre-installed from the device manufacturer and silently updated over the air by Google. Apps that use the Play Services SDK in theory can use all of the SDK's available APIs on all devices equipped with the Play Services Framework.

In practice, older devices (particularly Android 2.x) will have some number of limitations related to Play Services, not the least of which being the lack of automatic over-the-air updates. As many developers are now setting their `minSdkVersion` to be something newer (e.g., 15), this particular class of problems will tend to fall by the wayside.

…From the Standpoint of the Android Ecosystem?

Google's continued expansion of the Play Services SDK, sometimes at the expense of Android itself, has not proven to be universally popular:

- Developers who depend on the Play Services SDK will not be able to run on devices that lack the Play Services Framework. And while many people think that the only devices that matter have the Play Services Framework, some estimates indicate that over half of Android devices in use today are from manufacturers that are not part of the Google Play ecosystem.
- The Play Services SDK is closed-source, and as such it makes debugging certain classes of problem more difficult.
- The terms and conditions for using different aspects of the Play Services SDK may cause problems for some developers, ranging from interfering with their planned business model to interfering with their planned software license (e.g., GPL).

What Is In the Play Services SDK?

As mentioned earlier, the Play Services SDK is *vast*. The following sub-sections outline some of the major pieces of the Play Services SDK, what Gradle dependency pulls them in, and what independent alternatives exist (if any).

Android Pay / Google Wallet

Google has tried a couple of times to get into the mobile payments market, starting with Google Wallet, which has now morphed into Android Pay. If you want to allow users to purchase goods and services through your app, and you want to allow those users to pay via Android Pay, you can use this portion of the Play Services SDK.

Android Wear

To communicate from a device running an open source operating system (Android, on a phone or tablet) to a device running an open source operating system (Android, on an Android Wear device), you have to use a proprietary, closed-source library.

It is possible to show a `Notification` on a Wear device straight from the Android SDK. It is also possible to create a Wear app that exists standalone straight from the Android SDK. But if you want to send data to the Wear device from the phone or tablet, or vice versa, that requires the Wear portion of the Play Services SDK.

This library provides a few discrete APIs for communication:

- A shared data API, where both sides can read and write from a key-value store that is synchronized between the two environments
- A message API, for a classic point-to-point communications pattern
- An asset transfer API, designed for larger data sets (e.g., large images)

Google+

The documentation and business proposition for the Google+ API is a bit limited at this time. However, it appears that you can:

- add a +1 button to your app, if that sounds interesting
- have richer options for sharing content to a user's Google+ account, beyond simple `ACTION_SEND`
- examine the user's Google+ profile and some of the user's friends on Google+

Google Account Login / Sign In with Google

Rather than maintain your own account system, your app could ask the users to sign into their Google account as part of using your app.

Google Analytics

"Analytics" refers to tracking usage. Web analytics uses a mix of Web server logs, tracking cookies, and the like to determine popular Web pages, navigation flows, time spent in certain areas of a site, and so forth. Mobile analytics tracks usage within an app: certain activities, certain operations, etc.

Google Analytics is very popular for Web sites, and Google extended this to a mobile API designed for tracking app usage.

There are countless analytics services with Android APIs (e.g., Flurry) beyond Google's. While there appear to be few self-hosted or open source solutions, analytics data collection is not especially difficult to implement on your own, if you would prefer to keep this information more private. Data analysis is where the challenges with home-grown solutions arise. Or, you could simply not collect this sort of information.

Google App Indexing

Google App Indexing, among other things, allows for "deep links" into an Android app, surfaced from Google search results. That, on its own, does not require any particular proprietary APIs. However, to allow Google to discover these "deep links", it appears that you need to use a custom app-indexing API.

Google App Invites

Google's App Invites service allows your users to annoy their contacts, bugging them to install your app.

A simpler, albeit less slick, solution is to allow the user to send messages from your app with a link back to your app from its distribution channel (e.g., Play Store), such as via an `ACTION_SEND` `Intent`.

Google Cast

Google Cast can be thought of as a control protocol for Google Cast-enabled receivers. Through a Google-supplied SDK (or other means), Google Cast client apps ("senders") can direct a Google Cast-enabled receiver to play, pause, rewind, fast-forward, etc. a stream. Android TV devices and Chromecast devices are the primary Cast-enabled receivers.

Google Cast does assume that, in general, the media receiver runs its own OS and is capable of playing streaming media without ongoing assistance from the Google Cast client. Hence, the client is not "locked into" having to keep feeding content to the Google Cast client, allowing the user to go off and do other things with that client while playback is going on.

Chromecast offers up remote playback media routes and works with `RemotePlaybackClient`, as is discussed in the chapter on `MediaRouter`. The sample app for `RemotePlaybackClient` was tested on a Chromecast.

If you want greater control than is offered via `RemotePlaybackClient`, though, you can use the Cast SDK. However, using the Cast SDK will tie you to Google Cast — and some of its restrictions, both technical and legal — but will give you greater developer control over the behavior of both the Google Cast device and your app.

As noted above, `RemotePlaybackClient`, along with the `Presentation` API, offer a significant subset of what the Cast SDK offers.

Google Cloud Messaging

Google Cloud Messaging – GCM for short — asynchronously delivers notifications from the Internet ("cloud") to Android devices. Rather than the device waking up and polling on a regular basis at the behest of your app, your app can register for notifications and then wait for them to arrive. GCM is engineered with efficiency in mind:

- Apps do not have to be constantly running, maintaining their own socket connections to some XMPP or MQTT server (let alone several such apps)
- Apps can share a single managed connection to a Google server, one that is carefully tuned to minimize power draw while also keeping the connection alive
- Apps can avoid frequent wakeup events for polling, letting some server do the "heavy lifting" and just tap the app on the virtual shoulder to inform it of some data of interest

The proper use of GCM means better battery life for your users. It can also reduce the amount of time your code runs, which helps you stay out of sight of users looking to pounce on background tasks and eradicate them with task killers.

GCM has gone through four revisions of its API, including the 2016 rebranding of it as Firebase Cloud Messaging (FCM). Be sure to use up-to-date references and examples when adding GCM/FCM to your apps.

You may also encounter references to "C2DM", GCM's precursor. C2DM debuted in 2010 and quickly became popular, for everything from triggering near-real-time data synchronization (e.g., Remember the Milk to-do list updates) to lightweight coordination between multiple players in a game. However, C2DM was a Google Labs product and in perpetual beta form. When Google Labs was shut down, C2DM was in limbo: not canceled, but not converted into an actual product. In 2012, GCM formally replaced C2DM, and in 2015, C2DM was shut down entirely. Hence, while high-level concepts about push messaging from the C2DM era might still be relevant to you, any actual C2DM-related code will be useless.

Other devices from outside the Google Play ecosystem may offer their own counterparts to GCM. Independent push implementations can range from XMPP and MQTT to simple WebSockets, though these have limitations when compared to GCM.

Google Drive

Google Drive is Google's hosted file-storage service. Via Drive APIs in the Play Services SDK, you can work indirectly with the user's Google Drive-hosted content, including creating and deleting files, plus searching through files for ones that meet particular search criteria.

Note that some of this functionality is available via the Storage Access Framework in Android 4.4+, with the advantage that it works across multiple content sources, not just Google Drive.

Other services (e.g., Dropbox) have their own APIs as well.

Google Fit

Google Fit is Google's wearable sensor initiative, for "smartbands" and related gadgets. Through the Fit APIs, you can detect Fit gadgets associated with a user's device, read data from those gadgets' sensors (e.g., heart rate), and so forth.

Other manufacturers in this space (e.g., Fitbit) have their own SDKs as well.

Google Location Services

This portion of the Play Services SDK offers the "fused location provider". This combines GPS and network sources of location data, plus sensor information, to try to offer better location information with less power draw. For example, if the sensors suggest that the device is not moving, the fused location provider can scale back how aggressively it uses the location sources, since the location probably is not changing.

This library also offers a "geofencing" implementation, where you ask the Play Services SDK to keep track of certain locations and let you know if the device gets within a certain distance of those locations.

This book has a chapter on the fused location provider.

Google Maps

Android has offered integrated Google Maps to developers since the outset. With the introduction of Maps V2 in 2012, this capability was folded into the Play Services SDK. Through Maps V2, you can embed a map powered by Google Maps into your application, complete with markers and popups, lines and shaded areas, and so on.

This book has a chapter on Maps V2.

Due to the popularity of embedded maps, other manufacturers (e.g., Amazon, Blackberry) have offered their own map engines, often with APIs that attempt to mimic that of Maps V2 (or perhaps its predecessor, now known as Maps V1). Beyond that, there is the OpenStreetMap project, for which Android libraries are available.

Google Mobile Ads / AdMob

Google is an advertising company. They offer the Google Mobile Ads SDK (a.k.a., AdMob for Android) as part of the Play Services SDK, for you to be able to add banners, interstitials, and other forms of advertising to your app.

There are other competing mobile ad networks that you could consider, though you may be better served focusing on coming up with a better business model.

Google Mobile Vision

Google has a variety of APIs, grouped under the "Mobile Vision" banner, designed for detecting specific sorts of objects or other information in still photos and videos. These include:

- detection of faces, and the state of those faces (e.g., expressions)
- detection and decoding of barcodes

Android's native camera API has some amount of face recognition, though not to the level of the Face API in the Mobile Vision SDK.

There are a variety of barcode scanning apps (e.g., the legendary ZXing Barcode Scanner) and libraries (e.g., ZBar) that one can use independently of the Play Services SDK.

Google Nearby

Google Nearby offers a pair of APIs for communication between nearby devices.

The Nearby Messages API offers a publish-and-subscribe messaging framework, designed for sending small blocks of data between Internet-connected Android and iOS devices. This is largely frictionless for the user (beyond the network connection), as the Messages API uses a mix of radios (Bluetooth, Bluetooth LE, WiFi) and ultrasonic signaling to handle the pairing and interaction.

The Nearby Connections API offers connection-based group messaging between devices on the same WiFi network. While you can pass more data this way, since everybody has to be on WiFi, it reduces the number of potential communications partners.

While some aspects of Google Nearby (e.g., ultrasound) are unusual, there have been many projects offering server-less group communications, from ZeroMQ to AllJoyn.

SafetyNet

The SafetyNet APIs lets your app know "whether the device where it is running matches the profile of a device that has passed Android compatibility testing". Presumably, this is designed to help you detect custom ROMs or copies of your app installed from pirate sites onto incompatible hardware.

Adding Play Services to Your Project

On the surface, using Play Services should be simple: add the aforementioned `implementation` statement(s), then start calling some methods from the supplied Play Services SDK libraries.

Unfortunately, it is not that simple. There are a number of other things that you will need to deal with in order to integrate Play Services into your app.

The Metadata

You will see plenty of examples that show having a `<meta-data>` element, inside your `<application>` element, with an `android:name` of `com.google.android.gms.version` and a value pulling in an integer resource (`@integer/google_play_services_version`) from the Play Services SDK:

```
<application
  android:allowBackup="false"
  android:icon="@drawable/ic_launcher"
  android:label="@string/app_name"
  android:theme="@style/Theme.Apptheme">
  <activity android:name=".WeatherDemo">
    <intent-filter>
      <action android:name="android.intent.action.MAIN"/>

      <category android:name="android.intent.category.LAUNCHER"/>
    </intent-filter>
  </activity>
  <activity android:name=".LegalNoticesActivity"/>

  <meta-data
    android:name="com.google.android.gms.version"
    android:value="@integer/google_play_services_version"/>
</application>
```

(from Location/FusedNew/app/src/main/AndroidManifest.xml)

This is no longer required, if you are using version 8.1.0 or higher of the Play Services SDK. This element will be added to your manifest automatically via the manifest merger process.

Dealing with Runtime Permissions

Android 6.0's runtime permission system affects some of the Play Services APIs. For example, if you are trying to get the location via the fused location provider, you will need `ACCESS_COARSE_LOCATION` or `ACCESS_FINE_LOCATION`. Both of those are `dangerous` permissions, so apps with a `targetSdkVersion` of 23 or higher will need to request those permissions at runtime.

The `Location/FusedNew` sample application contains an `AbstractGoogleApiClientActivity` that, among other things, helps us deal with runtime permissions in our Play Services SDK-using apps.

Detecting If We Have Permission

The idea behind `AbstractGoogleApiClientActivity` is that apps using the Play Services SDK will have activities that inherit from `AbstractGoogleApiClientActivity`, overriding a few methods to configure how `AbstractGoogleApiClientActivity` handles things like runtime permissions. For example, `AbstractGoogleApiClientActivity` has an `abstract` method named `getDesiredPermissions()` that subclasses must override, providing a `String` array of permissions that the activity needs. `AbstractGoogleApiClientActivity` then uses `hasAllPermissions()` and `hasPermission()` private methods to determine whether all of the requested permissions are currently held:

```
private boolean hasAllPermissions(String[] perms) {
  for (String perm : perms) {
    if (!hasPermission(perm)) {
      return(false);
    }
  }

  return(true);
}

private boolean hasPermission(String perm) {
  return(ContextCompat.checkSelfPermission(this, perm)==
    PackageManager.PERMISSION_GRANTED);
}
```

(from Location/FusedNew/app/src/main/java/com/commonsware/android/weather2/AbstractGoogleApiClientActivity.java)

In `onCreate()` of `AbstractGoogleApiClientActivity`, among other things, we call `hasAllPermissions()` to see if we have all of our required permissions — if yes, we

can go ahead and call an `initPlayServices()` method to start the process of initializing our access to the Play Services SDK:

```
@Override
protected void onCreate(Bundle savedInstanceState) {
  super.onCreate(savedInstanceState);

  if (savedInstanceState!=null) {
    isInPermission=
      savedInstanceState.getBoolean(STATE_IN_PERMISSION, false);
    isResolvingPlayServicesError=
      savedInstanceState.getBoolean(STATE_IN_RESOLUTION, false);
  }

  if (hasAllPermissions(getDesiredPermissions())) {
    initPlayServices();
  }
  else if (!isInPermission) {
    isInPermission=true;

    ActivityCompat
      .requestPermissions(this,
        netPermissions(getDesiredPermissions()),
        REQUEST_PERMISSION);
  }
```

(from Location/FusedNew/app/src/main/java/com/commonsware/android/weather2/AbstractGoogleApiClientActivity.java)

Requesting Permissions

If we do not have all of the permissions, `onCreate()` will call `requestPermissions()` on `ActivityCompat` to ask the user for them. However, it also leverages `netPermissions()` to filter out the permissions that the user previously granted, so we only bother the user with permissions that either the user has not seen before or has previously denied:

```
private String[] netPermissions(String[] wanted) {
  ArrayList<String> result=new ArrayList<String>();

  for (String perm : wanted) {
    if (!hasPermission(perm)) {
      result.add(perm);
    }
  }
```

```
    return(result.toArray(new String[result.size()]));
  }
```

(from Location/FusedNew/app/src/main/java/com/commonsware/android/weather2/AbstractGoogleApiClientActivity.java)

Note that this code is not making use of `shouldShowRequestPermissionRationale()`, to detect previous permission denials and perhaps show some UI to educate the user on what the impacts are of this rejection.

Handling the Result

The call to `requestPermissions()` will eventually trigger a callback to `onRequestPermissionsResult()`. Here, if we now have all of the permissions, we call `initPlayServices()` (more on this in a bit) and then `connect()` to the Play Services SDK (also, more on this in a bit):

```
@Override
public void onRequestPermissionsResult(int requestCode,
                                       String[] permissions,
                                       int[] grantResults) {
  isInPermission=false;

  if (requestCode==REQUEST_PERMISSION) {
    if (hasAllPermissions(getDesiredPermissions())) {
      initPlayServices();
      playServices.connect();
    }
    else {
      handlePermissionDenied();
    }
  }
}
```

(from Location/FusedNew/app/src/main/java/com/commonsware/android/weather2/AbstractGoogleApiClientActivity.java)

If, however, we do not have all of the requested permissions, another `abstract` method on this class is `handlePermissionDenied()`, where the subclass can do what it wants to. That could range from explaining to the user what can and cannot be done to simply calling `finish()` and going away.

Dealing with Configuration Changes

There is a possibility that the user will rotate the screen or otherwise trigger a configuration change while we are in the request-permission process. Even though our activity is not in the foreground from an input standpoint, it *is* visible, and so it will undergo the configuration change while the request-permission dialog is still in the foreground. We do not want to pop up the dialog *again* (and confuse the user). So, the `isInPermission` field is tracking whether the request-permission dialog is outstanding, so we do not attempt to show the dialog again in `onCreate()`.

Since the activity could be destroyed and recreated as part of the configuration change, we hang onto the `isInPermission` value in the saved instance state `Bundle`:

```
@Override
protected void onSaveInstanceState(Bundle outState) {
  super.onSaveInstanceState(outState);

  outState.putBoolean(STATE_IN_PERMISSION, isInPermission);
  outState.putBoolean(STATE_IN_RESOLUTION,
    isResolvingPlayServicesError);
}
```

(from Location/FusedNew/app/src/main/java/com/commonsware/android/weather2/AbstractGoogleApiClientActivity.java)

(the `STATE_IN_RESOLUTION` bit will be explained shortly)

And, in `onCreate()`, we re-initialize `isInPermission` if we got the saved instance state `Bundle` passed in.

Checking for Play Services

While you typically think of Android devices as having Play Services, that is not always the case. Sometimes, they do not, yet wind up having a copy of your app anyway, perhaps through less-than-legal measures. Or, the device has Play Services, but it is not the latest version — perhaps the user missed a recent Play Services update due to international travel, taking up temporary residence in a Faraday cage, or other technical issues.

Hence, another thing that `AbstractGoogleApiClientActivity` does is confirm that the device has Play Services and can connect to the Play Services process for whatever particular API(s) we wish to use.

Initializing the GoogleApiClient

For many, though not all, Play Services APIs, you use a `GoogleApiClient` as your entry point for talking to Play Services. Some APIs, like Maps V2, do not use `GoogleApiClient` for some reason. But, more often than not, you will find yourself needing `GoogleApiClient`.

To create a `GoogleApiClient` instance, use a `GoogleApiClient.Builder`. As the class name suggests, `GoogleApiClient` is used as a client connection to many (but not all) Google Play Services APIs, and `GoogleApiClient.Builder` is a builder for building such a connection. In particular:

- We pass our `Activity` as our `Context`
- We call `addConnectionCallbacks()` to indicate what should be notified when our connection to the Play Services process is ready
- We call `addOnConnectionFailedListener()` to indicate what should be notified if we have a problem connecting to the Play Services process
- We call `build()` on the `Builder` to actually build the `GoogleApiClient`

This is handled by `initPlayServices()` on `AbstractGoogleApiClientActivity`, which we call once we have our permissions set up:

```
protected void initPlayServices() {
  playServices=
    configureApiClientBuilder(new GoogleApiClient.Builder(this))
      .addConnectionCallbacks(this)
      .addOnConnectionFailedListener(this)
      .build();
}
```

(from Location/FusedNew/app/src/main/java/com/commonsware/android/weather2/AbstractGoogleApiClientActivity.java)

This includes calling out to the subclass' implementation of `configureApiClientBuilder()`, where the subclass can use methods like `addApi()` to indicate specifically what parts of the Play Services family of APIs the activity wants to use.

Given that we have a `GoogleApiClient`, we need to `connect()` to it to be able to start requesting location data, then `disconnect()` from it when we no longer need that location data.

Disconnecting is easy: we do that in `onStop()` of `AbstractGoogleApiClientActivity`:

```
@Override
protected void onStop() {
  if (playServices!=null) {
    playServices.disconnect();
  }

  super.onStop();
}
```

(from Location/FusedNew/app/src/main/java/com/commonsware/android/weather2/AbstractGoogleApiClientActivity.java)

There are two places where we possibly call `connect()`. One is if we needed to ask for permissions, and the user granted them. In `onRequestPermissionsResult()`, after confirming that we do indeed have all necessary permissions, we call `initPlayServices()` and then immediately call `connect()` on the `GoogleApiClient`:

```
@Override
public void onRequestPermissionsResult(int requestCode,
                                       String[] permissions,
                                       int[] grantResults) {
  isInPermission=false;

  if (requestCode==REQUEST_PERMISSION) {
    if (hasAllPermissions(getDesiredPermissions())) {
      initPlayServices();
      playServices.connect();
    }
    else {
      handlePermissionDenied();
    }
  }
}
```

(from Location/FusedNew/app/src/main/java/com/commonsware/android/weather2/AbstractGoogleApiClientActivity.java)

If we did *not* need to request permissions, we call `connect()` in `onStart()`, mirroring the `onStop()` where we are disconnecting:

```
@Override
protected void onStart() {
  super.onStart();

  if (!isResolvingPlayServicesError && playServices!=null) {
    playServices.connect();
```

```
    }
  }
```

(from Location/FusedNew/app/src/main/java/com/commonsware/android/weather2/AbstractGoogleApiClientActivity.java)

The `isResolvingPlayServicesError` `boolean` value will be discussed a bit later in this chapter.

Connecting and Disconnecting

The call to `connect()`, in turn, will trigger calls to our `onConnected()` and `onDisconnected()` methods of the `GoogleApiClient.ConnectionCallbacks` interface, assuming all goes well. `AbstractGoogleApiClientActivity` does not provide those implementations; they are considered part of the `abstract` API and therefore need to be implemented by subclasses.

However, apparently it is possible for this connection attempt to fail. Exactly how and why it might fail is not well documented. If it fails, the `onConnectionFailed()` method from our `GoogleApiClient.OnConnectionFailedListener` implementation will be called. `onConnectionFailed()` is passed a `ConnectionResult` indicating what specifically went wrong.

It turns out that this `ConnectionResult` may contain a `PendingIntent` that can be used to try to help the user recover from whatever the problem was. The recipe that we have been given to try to use this is to call `hasResolution()` (to see if the `PendingIntent` exists) and to use `startResolutionForResult()` (to invoke the activity pointed to by the `PendingIntent`). Of course, `hasResolution()` may return `false`, and apparently the `PendingIntent` might be broken, so we have to handle those scenarios as well:

```
@Override
public void onConnectionFailed(ConnectionResult result) {
  if (!isResolvingPlayServicesError) {
    if (result.hasResolution()) {
      try {
        isResolvingPlayServicesError=true;
        result.startResolutionForResult(this, REQUEST_RESOLUTION);
      }
      catch (IntentSender.SendIntentException e) {
        playServices.connect();
      }
    }
    else {
      ErrorDialogFragment.newInstance(result.getErrorCode())
```

```
          .show(getFragmentManager(),
            TAG_ERROR_DIALOG_FRAGMENT);
        isResolvingPlayServicesError=true;
      }
    }
  }
```

(from Location/FusedNew/app/src/main/java/com/commonsware/android/weather2/AbstractGoogleApiClientActivity.java)

If we have a resolution and successfully start up the resolution activity, our activity will be stopped and later started, at which point we will wind up trying to `connect()` again naturally.

If there is no `PendingIntent` to try to resolve the problem, we can still attempt to display a dialog with information about what is going wrong. The Play Services SDK provides this dialog, though we are responsible for wrapping it in a `DialogFragment` ourselves. That comes in the form of `ErrorDialogFragment`:

```
public static class ErrorDialogFragment extends
  DialogFragment {
  static final String ARG_ERROR_CODE="errorCode";

  static ErrorDialogFragment newInstance(int errorCode) {
    Bundle args=new Bundle();
    ErrorDialogFragment result=new ErrorDialogFragment();

    args.putInt(ARG_ERROR_CODE, errorCode);
    result.setArguments(args);

    return(result);
  }

  @Override
  public Dialog onCreateDialog(Bundle savedInstanceState) {
    return(GoogleApiAvailability
      .getInstance()
      .getErrorDialog(
        getActivity(),
        getArguments().getInt(ARG_ERROR_CODE),
              REQUEST_RESOLUTION));
  }

  @Override
  public void onCancel(DialogInterface dlg) {
    if (getActivity()!=null) {
      getActivity().finish();
    }
```

```
    super.onCancel(dlg);
  }

  @Override
  public void onDismiss(DialogInterface dlg) {
    if (getActivity()!=null) {
      ((AbstractGoogleApiClientActivity)getActivity())
        .isResolvingPlayServicesError=false;
    }

    super.onDismiss(dlg);
  }
}
```

(from Location/FusedNew/app/src/main/java/com/commonsware/android/weather2/AbstractGoogleApiClientActivity.java)

`onCreateDialog()` uses the `GoogleApiAvailability` singleton to show the error dialog, given the error code that came from our previous attempt to connect. We pass that error code over to the `ErrorDialogFragment` via the arguments `Bundle`, so that it can survive a configuration change.

However, we also have to take into account that the device might undergo a configuration change while either the resolution activity started by `startActivityForResult()` or the `ErrorFragmentDialog` is in the foreground. What we do not want to do is immediately try connecting to Play Services again in `onStart()`, while we are in the process of trying to fix whatever problem prevented us from connecting to it previously.

So, we have to track a `boolean` state, `isResolvingPlayServicesError`, as a field in our activity. That is initially set to `false`, but we `flip` it to `true` if we show the resolution activity or the `ErrorFragmentDialog`. We flip it back to `false` when either the started activity returns control to us in `onActivityResult()` or when the `ErrorDialogFragment` is dismissed. While that flag is `true`, we skip attempting to connect to Play Services in `onStart()`. And this flag is part of our saved instance state, so we can handle configuration changes.

Getting Help

Obviously, this book does not cover everything. And while your #1 resource (besides the book) is going to be the Android SDK documentation, you are likely to need information beyond what's covered in either of those places.

Searching online for "android" and a class name is a good way to turn up tutorials that reference a given Android class. However, be sure to check the age of the blog post or whatever that you are reading. The older it is, the more likely that it is out of date, based upon changes in Android or just better solutions that have evolved over time.

Beyond randomly hunting around for tutorials, though, this chapter outlines some other resources to keep in mind.

Questions. Sometimes, With Answers.

Stack Overflow's android tag is the world's #1 place to get Android help. However, there are a variety of other sites offering help in a variety of languages.

It is important, particularly for Stack Overflow, to write well-written questions:

1. Include relevant portions of the source code (e.g., the method in which you are getting an exception) and the stack trace from Logcat, if the problem is an unhandled exception.
2. On Stack Overflow, make sure your source code and stack trace are formatted as source code; on Google Groups, consider posting long listings on gist.github.com or a similar sort of code-paste site.

3. Explain thoroughly what you are trying to do, how you are trying to do it, and why you are doing it this way (if you think your goal or approach may be a little offbeat).
4. On Stack Overflow, respond to answers and comments with your own comments, addressing the person using the @ syntax (e.g., `@CommonsWare`), to maximize the odds you will get a reply. However, only use that for people who are already involved in your question.
5. On the Google Groups, do not "ping" or reply to your own message to try to elicit a response until a reasonable amount of time has gone by (e.g., 24 hours).

Heading to the Source

The source code to Android is now available. Mostly this is for people looking to enhance, improve, or otherwise fuss with the insides of the Android operating system. But, it is possible that you will find the answers you seek in that code, particularly if you want to see how some built-in Android component "does its thing".

The source code and related resources can be found at http://source.android.com. Here, you can:

1. Download the source code
2. File bug reports against the operating system itself
3. Submit patches and learn about the process for how such patches get evaluated and approved
4. Join a separate set of Google Groups for Android platform development

Trail: Code Organization and Gradle

Working with Library Modules

Android library modules are the primary unit of Android source reuse, particularly where that source involves more than just Java source code, such as Android resources.

In this chapter, we will explore the basics of setting up and using an Android library module.

Prerequisites

Understanding this chapter requires that you have read the core chapters of this book.

Creating a Library Module

An Android library module, in many respects, looks like a regular Android project. It has source code and resources. It has a manifest.

What it does not do, though, is build an APK file. Instead, it represents a basket of programming assets that the Android build tools know how to blend in with regular Android projects.

Making a project be an Android library module is simply a matter of choosing the right Android Gradle Plugin.

Rather than have:

```
apply plugin: 'com.android.application'
```

use:

```
apply plugin: 'com.android.library'
```

That's it — the `com.android.library` plugin now knows that it is creating a library, not an app.

The real question is, *where* are you making this library? In many cases, you will do so as a module in a project, where there is another module that is an app. This covers both:

- A library designed to be standalone, but with a sample app demonstrating its use
- A library designed to be used by the app, and perhaps other app modules in this project

Adding new modules to an Android Studio project is handled most simply via the new-module wizard, which you can bring up via File > New > New Module... from the main menu. This brings up the first page of the new-module wizard:

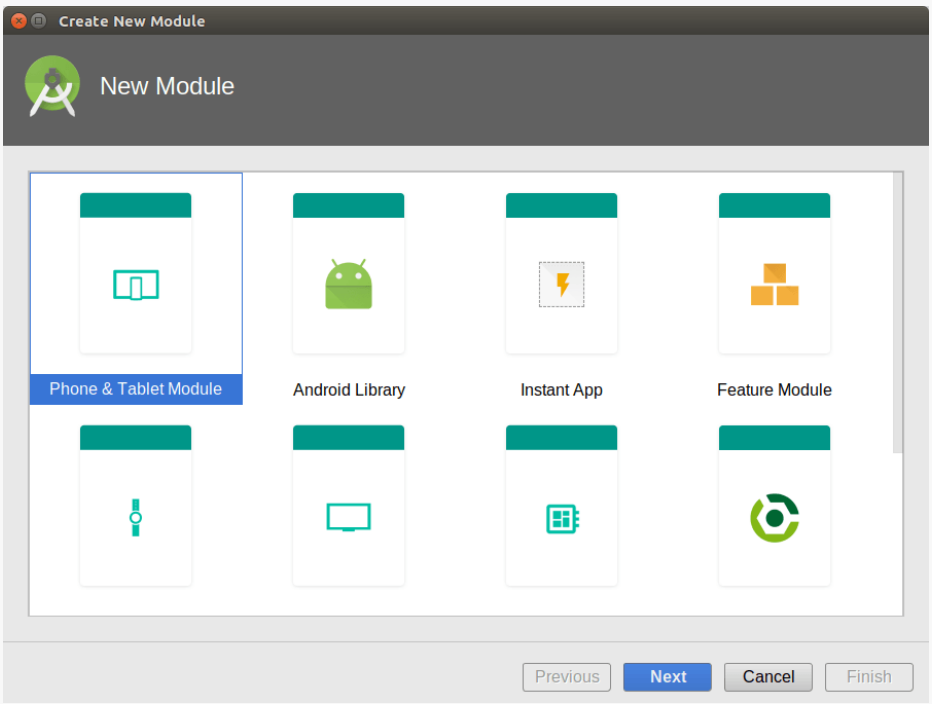

Figure 330: Android Studio New-Module Wizard, First Page

To add a library module as a module to an existing project, choose "Android Library" in the list of module types, then click Next to proceed to the second page of the wizard:

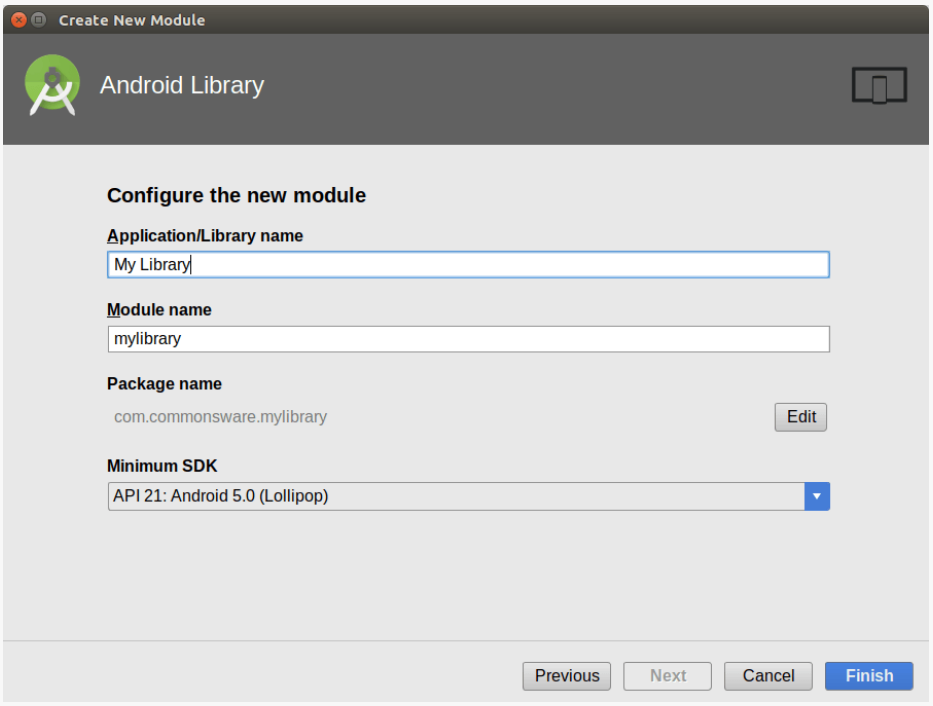

Figure 331: Android Studio New-Module Wizard, Second Page

This collects some bits of information, including:

- the "application name", whose use in this case is unclear
- the "module name", which will be the directory in this project into which this library will be created
- the "package name", which will go into the manifest of the generated library
- your module's `minSdkVersion`

At this point, clicking Next will take you to the same new-activity flow that you saw when creating a new project. If you want an activity to be generated for you in this library, proceed by selecting the activity template and providing the activity template configuration data. If you do not want an activity, choose "Add No Activity" in the grid of templates, then click "Finish" to create the module.

In the end, the new-module wizard will set up the new module for you, in your designated subdirectory of the project, including modifying `settings.gradle` to list

this subdirectory as being a module within the project. At this point, you will be able to start using the library within the project itself.

Using a Library Module

Once you have a library module, you can attach it to another Android module, so the other Android module has access to everything in the library. This works similarly to adding other sorts of dependencies, with a slight syntax change. Rather than use an artifact identifier or `fileTree()`, we use `project()`:

```
implementation project(':libname')
```

where `libname` is the name of the module. This will be the directory name, and it will also show up as the module's name in `settings.gradle` in the project root directory:

```
include ':app', ':libname'
```

The leading colon means that this module is directly off of the project root directory.

If you wish to use this library module in separate projects, other than the one that hosts the module, you will need to distribute it to those other projects. A typical way to do that is to compile the library module into an AAR file and have that be hosted in an artifact repository.

Library Modules and the Manifest

Library projects can publish their own `AndroidManifest.xml` file, which contributes to the overall manifest used by apps that incorporate the library. Hence, a library can:

- request permissions that perhaps are not in the app's own manifest
- publish activities or other components, without the app developer having to add entries to the app's own manifest
- stipulate a minimum SDK version required by the library code, which might be higher than the minimum SDK version required by the app itself

However, merging these manifests is a rather complex topic, and as such will be covered much later in the book.

Library Modules and Transitive Dependencies

Just as an application module can have dependencies, so can a library module. For other modules that depend upon the library module, the library module's dependencies become transitive dependencies. In other words, if App A depends upon Library B, and Library B depends upon Library C and Library D, App A has transitive dependencies on Library C and Library D.

When a module depends directly upon a library module (e.g., `implementation project(':libname')`), all of that library module's dependencies get added to the requesting module's dependencies list. The same holds true when a module depends upon a library from an artifact repository. It does *not* hold true for bare libraries, such as adding plain JARs to a project via `implementation fileTree(...)`.

There are three key ways that a library module can declare a dependency: `implementation`, `api`, and `compileOnly`. While an app module typically would only use `implementation`, all three of these options are possible for a library module, with subtly different behavior:

Configuration Name	Is Dependency's API Available to Hosts?	Is Dependency's Code Added to Hosts?
`implementation`	no	yes
`api`	yes	yes
`compileOnly`	no	no

Let's examine a concrete example: CWAC-NetSecurity. This library — which will be profiled later in the book — has its own code, plus it has helper code for integrating the library's code with OkHttp. There are three ways that CWAC-NetSecurity could declare its dependency upon OkHttp, and those choices change what happens in an app that itself depends upon CWAC-NetSecurity:

- If CWAC-NetSecurity uses `implementation` to depend upon OkHttp, then an app that depends upon CWAC-NetSecurity gets both CWAC-NetSecurity and OkHttp code added to the app ("Is Dependency's Code Added to Hosts?"). However, the OkHttp code itself is *not* deemed to be part of the API of CWAC-NetSecurity, and so the app that depends upon CWAC-NetSecurity cannot use the OkHttp classes, unless it has its own separate `implementation` dependency upon OkHttp.
- If CWAC-NetSecurity uses `api` to depend upon OkHttp, then as with `implementation`, both the code from OkHttp and the code from CWAC-

NetSecurity get added to apps that depend upon CWAC-NetSecurity. However, in this case, the app can directly refer to classes from either CWAC-NetSecurity or OkHttp, without an additional dependency declaration. In effect, CWAC-NetSecurity is stating that OkHttp is part of CWAC-NetSecurity's public API.
- What *really* happens is that CWAC-NetSecurity uses `compileOnly`. This says that OkHttp is used only to be able to compile CWAC-NetSecurity's own code. The OkHttp code is *not* added to apps that depend upon CWAC-NetSecurity, unless those apps have their own `implementation` dependency upon OkHttp.

`implementation` and `api` are the two most common. `compileOnly` is mostly for cases where the library module would like to offer integration for some third-party library, but where that library is not essential. For apps that want to use the integration, they simply need to have an additional dependency. For apps that *do not* want the integration, though, they avoid having all the extra code added from the third-party library.

Limitations of Library Modules

While library modules are useful for code organization and reuse, they do have their limits.

As noted above, if more than one project (main plus libraries) defines the same resource, the higher-priority project's copy gets used. Generally, that is a good thing, as it means that the main project can replace resources defined by a library (e.g., change icons). However, it does mean that two libraries might collide. It is important to keep your resource names distinct to minimize the odds of this occurrence.

Gradle and Tasks

A `build.gradle` file teaches Gradle how to execute tasks, such as how to compile an Android project. Outside of a Gradle-aware IDE like Android Studio, you use Gradle itself to run these tasks. If you have installed your own copy of Gradle, you would use the `gradle` command; if you are relying upon a trusted copy of the Gradle Wrapper, you would use the `./gradlew` script in your project root.

For the purposes of this book, the `gradle` command will be shown – just substitute `./gradlew` where you see `gradle` if you are using the Gradle Wrapper script.

Key Build-Related Tasks

To find out what tasks are available to you, you can run `gradle tasks` from the project directory. That will result in output akin to:

```
> Task :tasks

------------------------------------------------------------
All tasks runnable from root project
------------------------------------------------------------

Android tasks
-------------
androidDependencies - Displays the Android dependencies of the project.
signingReport - Displays the signing info for each variant.
sourceSets - Prints out all the source sets defined in this project.

Build tasks
-----------
assemble - Assembles all variants of all applications and secondary packages.
assembleAndroidTest - Assembles all the Test applications.
```

```
assembleDebug - Assembles all Debug builds.
assembleRelease - Assembles all Release builds.
build - Assembles and tests this project.
buildDependents - Assembles and tests this project and all projects that depend on it.
buildNeeded - Assembles and tests this project and all projects it depends on.
clean - Deletes the build directory.
cleanBuildCache - Deletes the build cache directory.
compileDebugAndroidTestSources
compileDebugSources
compileDebugUnitTestSources
compileReleaseSources
compileReleaseUnitTestSources
mockableAndroidJar - Creates a version of android.jar that's suitable for unit tests.

Build Setup tasks
-----------------
init - Initializes a new Gradle build.
wrapper - Generates Gradle wrapper files.

Help tasks
----------
buildEnvironment - Displays all buildscript dependencies declared in root project
'MyApplication'.
components - Displays the components produced by root project 'MyApplication'.
[incubating]
dependencies - Displays all dependencies declared in root project 'MyApplication'.
dependencyInsight - Displays the insight into a specific dependency in root project
'MyApplication'.
dependentComponents - Displays the dependent components of components in root project
'MyApplication'. [incubating]
help - Displays a help message.
model - Displays the configuration model of root project 'MyApplication'. [incubating]
projects - Displays the sub-projects of root project 'MyApplication'.
properties - Displays the properties of root project 'MyApplication'.
tasks - Displays the tasks runnable from root project 'MyApplication' (some of the
displayed tasks may belong to subprojects).

Install tasks
-------------
installDebug - Installs the Debug build.
installDebugAndroidTest - Installs the android (on device) tests for the Debug build.
uninstallAll - Uninstall all applications.
uninstallDebug - Uninstalls the Debug build.
uninstallDebugAndroidTest - Uninstalls the android (on device) tests for the Debug
build.
uninstallRelease - Uninstalls the Release build.

Verification tasks
```

```
------------------
check - Runs all checks.
connectedAndroidTest - Installs and runs instrumentation tests for all flavors on
connected devices.
connectedCheck - Runs all device checks on currently connected devices.
connectedDebugAndroidTest - Installs and runs the tests for debug on connected
devices.
deviceAndroidTest - Installs and runs instrumentation tests using all Device
Providers.
deviceCheck - Runs all device checks using Device Providers and Test Servers.
lint - Runs lint on all variants.
lintDebug - Runs lint on the Debug build.
lintRelease - Runs lint on the Release build.
lintVitalRelease - Runs lint on just the fatal issues in the release build.
test - Run unit tests for all variants.
testDebugUnitTest - Run unit tests for the debug build.
testReleaseUnitTest - Run unit tests for the release build.
```

This list is dynamically generated based on the contents of `build.gradle`, notably including tasks defined by the `com.android.application` plugin.

In principle, you are supposed to specify the entire task name when running that task. However, you can use shorthand, so long as it uniquely identifies the task.

Probably the most common task that a developer will use, at least in the short term, is `installDebug` (or `iD` for short). This will build a debug version of the app and install it on an available device or emulator. This roughly corresponds to `ant install debug` for those familiar with legacy Ant-based command-line builds.

Just as there is `installDebug`, there can also be `installRelease`. The `Debug` and `Release` portions of the task are not hard-coded, but rather are derived from the "build types" defined in the `build.gradle` file. The concept, role, and usage of build types will be covered in the next chapter. However, `installRelease` is not available by default, because installing an app requires that the APK be signed, and the Android Gradle Plugin does not know how to sign it. We will address this in the next chapter as well.

If you just want to build the app, without installing it, `assembleDebug` (`aD`) or `assembleRelease` (`aR`) will accomplish that aim. If you want to uninstall the app from a device or emulator, `uninstallDebug` (`uD`) and `uninstallRelease` (`uR`) should work.

Discussion of other tasks, such as the "check" tasks, will be covered in later chapters.

Results

All build output goes into a `build/` directory. Specifically, your APKs will go into `build/outputs/apk`, with different APK editions based upon whether you did a debug or release build.

Note that Gradle has a `clean` task that wipes out the `build/` directory.

Gradle Build Variants

You may think that the directory structure and files involved in an Android Studio project is a bit complicated. In truth, what you have seen so far is actually fairly simple, when you start to consider the real world of product development. Simple apps can get by with simple structures like we have seen so far, but:

- Many development teams want different behavior for debug builds instead of production builds, such as hitting a test server rather than the real app server
- Some development teams have different variations on the same app, tailored to different audiences, such as for distribution through different channels

In this chapter, we will explore the concept of "build variants" in Gradle and Android Studio and how you can take advantage of them for your projects.

Prerequisites

Understanding this chapter requires that you have read the chapters the core chapters of the book.

Objectives of the Project Structure

In the beginning, Android apps tended to be pretty simple, as we only had a handful of devices, a smattering of users, one primary distribution channel (the then-Android Market) and few major investors in the Android ecosystem.

Times have changed.

Now, Android apps for public consumption can be terribly complex, let alone apps for internal enterprise use (which seem to be complex as a side effect of being developed by an enterprise). We have multiple distribution channels, such as the Amazon AppStore for Android and Yandex.Store. We have a billion devices and nearly a billion users. Brands large and small are flocking to Android, bringing with them their own challenges.

The new build system is designed to simplify creating complex Android applications, while, ideally, not making simple Android applications a lot harder. It is designed for scenarios like:

- Supporting multiple distribution channels, which may require multiple in-app purchasing engines
- Supporting one app that is customized for individual clients, such as for use by different enterprises
- Supporting an app that really needs to have different APKs for different types of devices, despite all efforts to support all devices from a single APK
- Supporting an app that is part of a much larger integrated system and needing to be built as part and parcel of that larger system
- Supporting a fleet of apps that depend upon common code, resources, third-party libraries, and the like
- And so on

The new project structure, coupled with the Android Gradle Plugin and Gradle itself, makes all of this possible... albeit with a bit of a learning curve.

Terminology

To understand what the new project structure entails, we need to define a few terms, from Gradle and the Android Gradle Plugin.

Source Sets

To quote the Gradle documentation: "A source set is simply a group of source files which are compiled and executed together." Here, "source" means all the inputs that you are creating for the app, such as Java source code, Android resources and manifest files, and the like. This is in contrast to *dependencies*, which are inputs that you are (usually) obtaining from other developers, such as reusable libraries.

source sets, on their own, have no particular semantic meaning. You can elect to have your project use a single source set, or several source sets, for organizing your code. You might have different source sets for:

- Production code versus test code, replacing the separate test project that we historically used in Android development
- Interface code versus implementation code
- Different major functional areas within the app, particularly if they are maintained by separate teams or developer pairs
- And so on

As we will see, the new project structure assumes the existence of at least one source set, typically named `main`, but other features of the new build system will involve additional source sets.

Build Types

A build type is one axis of possible alternative outcomes from the build process.

By default, the Android Gradle Plugin assumes that you want two build types: release and debug. These may go through somewhat different build steps, such as applying ProGuard to the release build but skipping it for the debug build.

The Android Gradle Plugin though allows build types to have slightly different configurations, such as adding a `.debug` suffix to the APK's package name, so that you can have a release build and a debug build of your app on the same device at the same time. You also can create new build types for handling different scenarios. The new build system documentation, for example, suggests a separate "jnidebug" build type, where you can indicate that the Linux `.so` files for a project should be compiled in debug mode.

As we will see, creating a new build type involves modifications to the `build.gradle` file and adding a matching source set.

Product Flavors

A build type is one axis for varying your output. A product flavor is another, independent axis for varying your output.

Product flavors are designed for scenarios where you want different release output for different cases. For example, you may want to have one version of your app built

to use Google's in-app purchasing APIs (for distribution through the Play Store) and another version of your app built to use Amazon's in-app purchasing APIs (for distribution through the Amazon AppStore for Android). In this case, both versions of the app will be available in release form, and you may wish to have separate debug builds as well. And *most* of the code for the two versions of the app will be the same. However, you will have different code for the different distribution channels — not only does the right code have to run for the right channel, but there is no particular value in distributing the code for one channel through the other channel.

Another example would be an app that is branded and configured for different enterprise customers. You see this a lot with Web apps — the vendor sells a branded-and-configured version of the Web app to the customer, whether that app runs on vendor-supplied hardware or customer-supplied hardware. Similarly, the maker of an Android app for collecting employee timesheets might want to offer to its customers for *their* version of the timesheet app to sport the customer's logo, tie into the customer's specific accounting server, enable or disable features based upon how the customer uses timesheets, and so on. However, *most* of the code is shared between all customers, and so when the app is updated to add features or fix bugs, new builds are needed for *all* of the customers. In this case, each customer can be set up as an independent product flavor, sharing much of the code, but with slightly different code, resources (e.g., logo), and configuration based upon that customer's needs.

Product flavors are optional. If you do not describe any product flavors in your `build.gradle` file, it is assumed that you have a single product flavor, referred to internally as `default`. Many apps will not need product flavors; this is a feature that you will opt into as needed.

As we will see, creating a new product flavor involves modifications to the `build.gradle` file and (usually) adding a matching source set.

Build Variants

The term "build variant" is used for the cross product of the build types and the product flavors. So, a project with `debug` and `release` build types and `google` and `amazon` product flavors will result in a total of four build variants by default:

1. `debug` + `google`
2. `debug` + `amazon`
3. `release` + `google`
4. `release` + `amazon`

Flavor Dimensions

Sometimes, even this is insufficient flexibility, such as the `google` and `amazon` scenario described earlier in this section. Or, you might need separate `free` versus `paid` editions, if you want to have an up-front fee for accessing a premium version of your app.

Product flavors are considered to be part of a "flavor dimension". All flavors have to be a part of a flavor dimension, starting with Android Studio 3.0 — previously, they could be part of a default flavor dimension. You can have as many flavor dimensions as you need (e.g., one for free versus paid, one for distribution channel).

These then add another factor into the cross-product that determines your build variants. Suppose we have a `dist` flavor dimension, consisting of `free` and `paid` product flavors, and we have a `channel` flavor dimension, consisting of `google` and `amazon` flavors. Now, we have a total of *8* possible build variants, when we factor in the build types:

1. `debug` + `google` + `free`
2. `debug` + `amazon` + `free`
3. `release` + `google` + `free`
4. `release` + `amazon` + `free`
5. `debug` + `google` + `paid`
6. `debug` + `amazon` + `paid`
7. `release` + `google` + `paid`
8. `release` + `amazon` + `paid`

Configuring the Stock Build Types

The `debug` and `release` build types are ready "out of the box" for your use, with a reasonable set of defaults. However, you can change those defaults and make other adjustments to how those build types work, in addition to defining your own build types. Here, we will look at the options for changing the behavior of any build type, focusing on the stock `debug` and `release` build types.

Source Sets

Each build type can have its own associated source set. If you skip the directory for it, that means that the build type is not contributing changes to the `main` source set.

For example, later in the book, we will take a look at Stetho, a diagnostic library that you can add to your Android app to help understand what is going on inside of it. This code is handy during development, but it is *not* the sort of thing that you want to be shipping in production. Instead, you want to use it only for `debug` builds.

So, in the `Diagnostics/Stetho` sample project, we have not only a `main` source set, but also a `debug` source set alongside `main`. In `debug`, we have an `AndroidManifest.xml` file:

```
<?xml version="1.0" encoding="utf-8"?>
<manifest xmlns:android="http://schemas.android.com/apk/res/android"
  xmlns:tools="http://schemas.android.com/tools"
  package="com.commonsware.android.stetho"
  android:versionCode="1"
  android:versionName="1.0">

  <application
    android:name="com.commonsware.android.stetho.StethoApp"
    tools:replace="android:name">
  </application>

</manifest>
```

(from Diagnostics/Stetho/app/src/debug/AndroidManifest.xml)

The `com.commonsware.android.stetho.StethoApp` Java class referenced in the `<application>` element also resides in the `debug` source set.

We will see how these blend in with the contents of our `main` source set later in this chapter.

build.gradle Settings

We can also use the `buildTypes` closure in `build.gradle` to configure the behavior of the `debug` and/or `release` build types.

For example, a very popular thing to use is `applicationIdSuffix`, to append a value onto the application ID for builds of a particular build type. This allows the application ID for that build type to be different than the application ID of other build types of the same app. In other words, you can have `debug` and `release` builds installed on the same device at the same time.

As was noted earlier in the book, the `defaultConfig` closure allows us to change aspects of what is found in the `AndroidManifest.xml` file, replacing anything found in the actual file from the `main` source set.

Similarly, the `buildTypes` closure is where we configure the behavior of the build types. Each build type to be configured gets its own closure inside of `buildTypes`, and in there we can override various properties.

Notable properties that we can specify for a build type include:

- `debuggable` (to override `android:debuggable` from the `<application>` element in the manifest, to indicate that the app should be considered debuggable)
- `applicationIdSuffix` (to append to the package name specified by the manifest or the `defaultConfig` `applicationId` property)
- `versionNameSuffix` (to append to the version name specified by the manifest or the `defaultConfig` `versionName` property)

So, we can have:

```
buildTypes {
    debug {
        applicationIdSuffix ".d"
    }
}
```

Our `debug` build type adds suffixes to the application ID role for the package name. Note that altering the application ID *only* affects the package name as seen by Android when the app is installed and when the app is run. It does *not* affect the directory in which the `R` class is built, which uses the package name from the `AndroidManifest.xml` file. It also does not affect any of the Java packages for our own classes, which are whatever we used when we wrote them. Hence, much of our code will be oblivious to the package name change. However, if you want to reference the *real* package name, such as for looking things up in `PackageManager` or for use with constructing a `ComponentName`, use `getPackageName()` on any `Context` (like an `Activity`), rather than some hard-coded string, as `getPackageName()` returns what the runtime environment thinks the package is, which will include any suffixes added during the build process. Or, use `BuildConfig.APPLICATION_ID`, in cases where you do not have a `Context` handy on which to call `getPackageName()`.

We can also have a `signingConfig` property, for configuring how our APK files are digitally signed. This will be covered in a later chapter.

Order of Precedence

Properties defined for a build type, and the properties defined for the `defaultConfig` will override their equivalents in the `AndroidManifest.xml` file. However, a build type's source set can *also* have its own `AndroidManifest.xml` file. The overall order of precedence is:

- What is in `build.gradle` takes precedence over...
- ...what is in a build type's `AndroidManifest.xml` file, which takes precedence over...
- ...what is in the `main` `AndroidManifest.xml` file

However, merging manifests in general is a complex topic, with a separate chapter later in this book.

Resources from the build type's source set are merged into the resources from the `main` source set, and if there are collisions, the build type's resource takes precedence. The same is true for assets.

However, the behavior of Java source is slightly different. The build type's source set is still merged with the `main` source set, but if there is a collision, the result is a build error. Either the build type or the `main` source set can define any given source file, not both. So, while `debug` could have one version of `your/package/name/Foo.java` and `release` could have a different version of `your/package/name/Foo.java`, `main` could not *also* have `your/package/name/Foo.java`. Hence, if you define a class in a build type, you may need to define that class in *all* build types, so that any references from `main` to that class are satisfied for all build types.

One case where this would not be required would be for debug-only activities. Suppose that you wanted an activity in your app to provide diagnostic information to developers of that app regarding the state of caches and other in-memory constructs. While you could get at that stuff via a debugger, that is sometimes annoying, and just tapping on a launcher icon can be easier. But you do not want, let alone need, this diagnostic activity in your release builds. To make this work, you would put the activity's Java class only in the `debug` source set, along with its resources and manifest entry (complete with `MAIN/LAUNCHER` `<intent-filter>`). Since the `main` source set does not refer to your diagnostic activity, there is no requirement for the `release` build type to have an implementation of that Java class.

Adding Build Types

Many developers will fare just fine with the `debug` and `release` build types, perhaps with some adjustments as shown above. A few developers, though, will have other scenarios that warrant new build types. Fortunately, adding a new build type is rather easy.

First, pick whether you want to have the new build type start with the settings from `debug` or `release`. Then, use `initWith` to create a new build type initialized from that existing build type:

```
    buildTypes {
        debug {
          applicationIdSuffix ".d"
          versionNameSuffix "-debug"
        }

        dogfood.initWith(buildTypes.debug)

        dogfood {
            applicationIdSuffix ".dawg"
        }
    }
```

Here, we define a new `dogfood` build type, with its own application ID suffix.

As with the built-in build types, your new build types can have their own source sets, by adding the appropriately-named directories underneath `src/`.

Now, we gain Gradle tasks with `Dogfood` in the name, like `installDogfood`, to go along with their `Debug` and `Release` counterparts.

Adding Product Flavors and Getting Build Variants

Many apps will not need product flavors, but some will. Adding a product flavor is similar, in many respects, to adding a build type.

This involves two steps:

1. Having a `flavorDimensions` statement in the `android` closure, to define the flavor dimension(s) that you wish to use

2. Having a `productFlavors` closure where you define the flavors and their properties, including what dimension they belong to

```
flavorDimensions "channel"

productFlavors {
    goog {
        dimension "channel"
        applicationId "com.commonsware.android.awesomeapp.goog"
    }

    amzn {
        dimension "channel"
        applicationId "com.commonsware.android.awesomeapp.amzn"
    }
}
```

Here, we define one flavor dimension (`channel`) and two product flavors (`goog` and `amzn`), assigning a distinct `applicationId` to each of those flavors.

The `defaultConfig` is implemented using the same object type as is used for product flavors. Hence, we can configure the same things on a product flavor that we can on the `defaultConfig`, such as `applicationId`, as is done in this `build.gradle` file.

We could have source sets for each of these as well. For example, the `goog` source set might contain code that is used only for Google Play ecosystem devices (e.g., Play Services), while `amzn` might contain code used for devices distributed by other channels.

In terms of order of precedence:

- Product flavors override the `main` source set and the `defaultConfig`
- Build types override the product flavors

Our task names get more numerous and more complicated, to reflect the cross product of the product flavors and build types. Now, rather than `installDebug`, and `installRelease`, we have:

- `installAmznDebug`
- `installAmznRelease`
- `installGoogDebug`
- `installGoogRelease`

Doing the Splits

The Android Gradle Plugin offers `splits` as a lightweight canned replacement for product flavors for two scenarios:

- Having different APK files with different NDK binaries for ARM vs. x86 (vs. anything else)
- Having different APK files with resources for a specific screen density, important for those apps that have so many graphics that they are bumping up against distribution channel limits (e.g., 100MB on the Play Store, up from an earlier 50MB limit)

All you as a developer do is request that a particular split be enabled, with limited configuration. Notably, you do not have separate Gradle configuration (e.g., `applicationId`) nor source sets for splits. That allows splits to be processed more quickly at build time, as the build tools can make some simplifying assumptions and avoid a lot of recompiling.

Scoping Your Splits

A split, by default, will generate one APK per *possible* type of output. For example, splitting on density will give you one APK for `ldpi`, `mdpi`, `tvdpi`, `hdpi`, `xhdpi`, `xxhdpi`, and `xxxhdpi`. Plus, in the case of density, you also get one "universal" APK containing support for all densities by default.

That's nice... but what if you do not need separate APKs for all of those densities? For example, if you do not ship `tvdpi` resources, there is little reason to set up an APK for it separate from, say, the `hdpi` APK.

There are two basic patterns to controlling the scope of what gets built:

1. Use an `exclude` statement to start with the defaults and remove some options
2. Use a `reset()` method to wipe out the defaults, then use an `include` statement to list what you want

In other words, `exclude` implements a blacklist, and the `reset()/include` combination implements a whitelist. All else being equal, a whitelist is probably a better choice, so you can explicitly line it up with what you have written in your app.

Requesting NDK Splits

In your `android` closure, you can add a `splits` closure, containing an `abi` closure, which in turn sets up the APK splits by CPU architecture:

```
splits {
  abi {
    enable true
    reset()
    include 'armeabi-v7a', 'x86'
    universalApk true
  }
}
```

Here, we:

- Enable the split (`enable true`)
- Remove the default ABIs to be included (`reset()`)
- List the ABIs that we want to be included (`include 'armeabi-v7a', 'x86'`)
- Request that a "universal APK" also be created, containing all ABIs (`universalApk true`)

The latter would be useful for distribution channels that do not allow you to upload multiple APK files for different CPU architectures. This way, you can at least distribute your app there, even if it takes up more disk space than you like. By default, for the CPU architectures, you do not get a "universal APK".

Requesting Density Splits

The same basic pattern can be implemented for densities:

```
splits {
  density {
    enable true
    reset()
    include 'hdpi', 'xhdpi', 'xxhdpi'
  }
}
```

Once again, we enable the split, reset the defaults, then opt into the densities that we want.

Note, though, that a "universal APK" is always generated for densities. We do not need to have `universalApk true`, and it would appear that `universalApk false` is not an option at the present time.

Gradle and Android Studio

While most of the work involving build variants revolves around the module's `build.gradle` file, there are some things to consider when working with build variants within Android Studio.

The Build Variants View

When we run our project, Android Studio does not prompt us for a build type or a product flavor. It just runs the project. This begs the question of how Android Studio is determining which build variant is the one to run.

This is handled by the Build Variants view, usually docked on the left side of the Android Studio IDE window:

![Build Variants View, for a Simple Project](andproj-source sets3.png)

Each of your app's modules is shown, along with the current build variant that will be used if you run that module. Tapping on the build variant will allow you to choose an alternative build variant:

![Build Variants View, for a Project with Custom Build Types and Product Flavors](andproj-source sets4.png)

The Android Project View

Earlier in the book, when introducing Android Studio, we saw the Android project view. Elsewhere, we saw how the Android project view can help you manage resources across multiple resource sets.

Just as the Android project view "collapses" resource set, it also collapses source sets:

![Android Project View, Showing Java Source](andproj-source sets1.png)

Here, we have two editions of the `com.commonsware.myapplication` package. One is just the package name, while the other has "(androidTest)" appended to it. That, as you might imagine, reflects the `main` and `androidTest` source set, respectively:

![Classic Project View, Showing Java Source](andproj-source sets2.png)

This may be a bit useful between `main` and `androidTest`. It is likely to be far more useful if you employ product flavors, as your classes for the flavors will appear side-by-side... at least for the currently-selected flavor in the Build Variants view.

Flavors, Build Types, and the Project Structure Dialog

You are welcome to use the Build Types and Product Flavors tabs in the project structure dialog to maintain these portions of your `build.gradle` file, at least for simpler scenarios.

Manifest Merger Rules

When Android library projects were added as an option for app development, one problem became apparent: while libraries could contribute code and resources, they could not contribute manifest entries. Developers using libraries would sometimes have to add elements to their app manifest at the request of library authors, to add permissions, define components, and the like.

The Android Gradle Plugin has a robust set of rules for "manifest merger". While the term "manifest merger" is still used, in reality, the Android Gradle Plugin synthesizes a manifest for your app from a variety of sources, including apps, libraries, and `build.gradle` files, also varying based upon build types and product flavors.

This chapter will help to explain a bit more about what is possible what the rules are for the manifest merger process.

Prerequisites

Understanding this chapter requires that you have read the chapters that introduce Gradle and cover basic Gradle/Android integration, including build variants.

Manifest Scenarios

You might be wondering "why do we need all of this?" That is a fair question. Certainly, we were able to get by for quite a while without this sort of flexibility and accompanying confusion.

Here are some scenarios which help explain what you will get out of the manifest merger capabilities.

Library Manifest and App Manifest

A library — whether one of yours or one obtained via an AAR artifact from some repository — may need to augment the app's manifest. For example:

- a library for an ad network might require the `INTERNET` permission, so that apps that do not directly use the Internet still wind up requesting that permission
- a library providing a canned "about" activity might want to inject the `<activity>` element that you can use without requiring the developer to add it manually
- a library needs to be able to specify the `minSdkVersion` that it requires, which might supersede the value specified by the app, so the combined whole uses the most conservative value

App Manifest and Build Types

You may have particular needs for your main application that vary based upon build type that affect the manifest versus other things (e.g., ProGuard configuration).

For example, it may be that in debug builds, you want to have an activity that you can bring up, perhaps through `adb shell am`, that will give you diagnostic information about the app itself, or starts some diagnostic service that you can then access through your development machine's Web browser. In this case, that activity and that service would only be desired in `debug` builds, not `release` builds. And while the activity and the service code would simply be in the `debug` source set, you also need to merge in the manifest `<activity>` and `<service>` elements, plus perhaps other things (e.g., extra `<uses-permission>` elements that those diagnostic components need but the rest of the app does not).

App Manifest and Product Flavors

Product flavors can override values from the `defaultConfig`, such as defining distinct `applicationId` values, and that needs to be taken into account in the combined app.

Also, product flavors might need their own manifest entries to accommodate distribution channel-specific APIs, such as swapping between Play Services and Amazon equivalents for in-app purchasing or maps.

Combo Platters

And, of course, you may have some mix of all of the above.

Pieces of Manifest Generation

When you build your app, the build tools will combine information from all of the aforementioned sources to synthesize "one true manifest" that is used for the build.

However, there may be overlaps in what the sources provide, such as both a library and the app specifying a `minSdkVersion`. Hence, there are some basic rules and control structures that you have to manage the generation process, at least somewhat.

Merger Rules

Generally speaking:

- the manifests and Gradle configurations for product flavors and build types will override...
- the app's `main/` manifest, which will override...
- the manifest of any libraries

Libraries will be considered in the order of declaration — in other words, the order that they appear in the `dependencies` closure. This includes transitive dependencies, where one dependency requires another dependency, though the exact rules here are presently unclear.

For any given element or attribute, there are specific rules for how conflicts are resolved. We will explore those later in this chapter.

Note that values in `build.gradle`, such as the `defaultConfig` closure and its `minSdkVersion` and such, trump everything that result from the merger of disparate manifests from different sources.

Markers and Selectors

Through `tools:` attributes in the manifests that you control (i.e., not manifests from third-party libraries), you will be able to override the default rules for conflict resolution.

For example, a library might declare a particular theme to use for an activity that it publishes. That might be a reasonable default theme, but you may wish to override that theme in your app. A `tools:replace` attribute, in your `<activity>` element, will be able to teach the build tools that your `android:theme` value should replace the one from the library, whereas normally a conflict on an attribute like this would result in a build error.

You can also use "selectors" to help control in which scenarios a particular marker is applied, such as applying a marker only for a conflict arising from a specific library.

These markers and selectors will be explored in greater detail later in this chapter.

Placeholders

Sometimes, the "merger" we want to do involves something more involved.

For example, the `applicationId` and `applicationIdSuffix` properties that we set in various places in `build.gradle` can be used to allow for different variants of our builds to be installed at the same time on the same device. However, that is only true some of the time. If an app publishes a `ContentProvider`, not only does the application ID have to be unique, but so does the authority (or authorities) supported by that `ContentProvider`. This is not handled automatically, and so even though you might have the application ID distinct for different build variants, they still would conflict at install time because their provider authorities were the same.

The manifest generation process supports the notion of placeholders, where for string values in the manifest — like the `android:authorities` attribute on a `<provider>` — you can "splice in" dynamic values. One dynamic value that you can use "out of the box" is your build variant's `applicationId`, so you can have something like:

```
android:authorities="${applicationId}.provider"
```

to have the authority for the provider match the build variant's `application`, but with a `.provider` suffix.

We will explore the rules around these placeholders later in this chapter.

Examining the Merger Results

The generated manifest, combining the contents of all the manifests from the app, build types, product flavors, and libraries, will wind up in the `build/intermediates/manifests/` directory of your module (e.g., `app/`). Inside that directory will be subdirectories associated with each build variant, and in those subdirectories reside the generated manifest for that build variant.

The `Manifest/Merger` sample application is designed to illustrate how these merger rules work. Note that the application does not run — it exists merely to show the results of building the APK and, along the way, generating the manifests.

This project contains an app module (`app/`) and a library module (`lib/`), with the app depending upon the library. The app module has source sets for both `main/` and `debug/`, the latter for debug builds. The app module also defines two product flavors, `chocolate` and `vanilla`, with a source set for `vanilla/`. All three source sets (`main/`, `debug/`, `vanilla/`) have their own `AndroidManifest.xml` files. Adding in the manifest from the library, and you have four manifests in total that may be used to create the manifest for the app. In particular, for a `vanilla debug` build, all four manifests will be relevant and merged together.

If you build the project, particularly via the `gradle` command, you will get manifests based on what builds you create. For example, `gradle assembleVanillaDebug` will create a generated manifest in `build/intermediates/manifests/vanilla/debug/`.

As you are trying to determine how manifest merging is working in your project, you may find it useful to peek at these generated manifests from time to time... as we will here in this chapter.

Viewing Merged Manifests in Android Studio

Far and away the easiest way to see the effects of manifest merger on your app is to use Android Studio 2.2 (or higher) and its manifest merger viewer.

When you open a manifest in Android Studio, there are two sub-tabs. One, named "Text", has the XML editor where you define the manifest contents. The other, named "Merged Manifest", shows the results of the manifest merger process, using whatever build variant you have chosen for the module in the Build Variants tool.

The “Merged Manifest” tab has two panes: a tree of XML on the left, and a legend on the right:

Figure 332: Merged Manifest Tab

The contributors to the merged manifest are color-coded, to help make it easy for you to see where a particular element or attribute came from. You can get additional details by clicking on attributes or elements, as we will see when we work through some examples throughout this chapter.

Merging Elements and Attributes

Different sources of manifest data can contribute elements to the generated combined manifest. In many cases, these elements do not conflict, such as a library contributing a `<uses-permission>` element to an app. However, sometimes, what one source of manifest data wants is different than what another source of manifest data wants, and for that, we need to settle out what the generated manifest will contain.

Basic Merger Rules

Many element names can appear several times in a manifest, such as multiple `<uses-permission>` elements. Many of those have an identifier, usually `android:name`, that distinguishes one from the next. In general, if two manifest sources both contribute the same element (i.e., same element name, same `android:name` value), those two elements are themselves merged, which means:

- Any attributes that are in one, but not the other, are added to the combined element
- Any attributes that are in both, and are not identical in value, result in a merge conflict compile error, unless the resolution is specified via a marker
- All child elements (e.g., `<intent-filter>` inside of an `<activity>`) are merged, applying the same rules

Of course, if one manifest supplies a specific element instance, and others do not, then the specific element instance is simply included without worrying about any other merge logic.

Singleton elements — ones that could only ever appear once in the manifest — are treated as matching if they exist in more than one manifest. So, for example, the `android:versionCode` and `android:versionName` attributes of the `<manifest>` element are merged, as are attributes of `<support-screens>`, each of which can only exist once.

Example #1: Manifest Attributes

The `main/` version of the manifest defines an `android:versionName` attribute:

```
<manifest xmlns:android="http://schemas.android.com/apk/res/android"
  package="com.commonsware.android.merger"
  android:versionName="1.0 Main">

  // other stuff here

</manifest>
```

None of the other manifest versions do. Hence, the `main/` version of the manifest "wins", and its `android:versionName` is used (only to perhaps be overridden by `build.gradle` values):

```
<manifest xmlns:android="http://schemas.android.com/apk/res/android"
  package="com.commonsware.android.merger.vanilla"
  android:versionCode="1"
  android:versionName="1.0 Main" >

  // other stuff here

</manifest>
```

Here, we are showing the results of building the `vanilla` `debug` version of the app, so the package name reflects the `applicationId` defined in `build.gradle` for the `vanilla` product flavor:

```
productFlavors {
  vanilla {
    applicationId "com.commonsware.android.merger.vanilla"
  }

  chocolate {
    applicationId "com.commonsware.android.merger.chocolate"
  }
}
```

Similarly, the `versionCode` shows up because it is defined in `build.gradle`:

```
  defaultConfig {
    applicationId "com.commonsware.android.merger"
    minSdkVersion 15
    targetSdkVersion 19
    versionCode 1
  }
```

However, since `build.gradle` did not specify `versionName`, the version name comes from the manifests.

If another manifest also defined `android:versionName`, its value would need to match that of the one in `main/`, or you will get a build error from the Android Gradle Plugin... unless you use a marker, described later in this chapter.

The "Merged Manifest" view shows `android:versionName` as coming from the `main` manifest. However, as of Android Studio 2.2, contributions from Gradle are not color-coded separately, so we cannot distinguish that the `android:versionCode` really came from Gradle, not from a manifest... unless you click on the attribute:

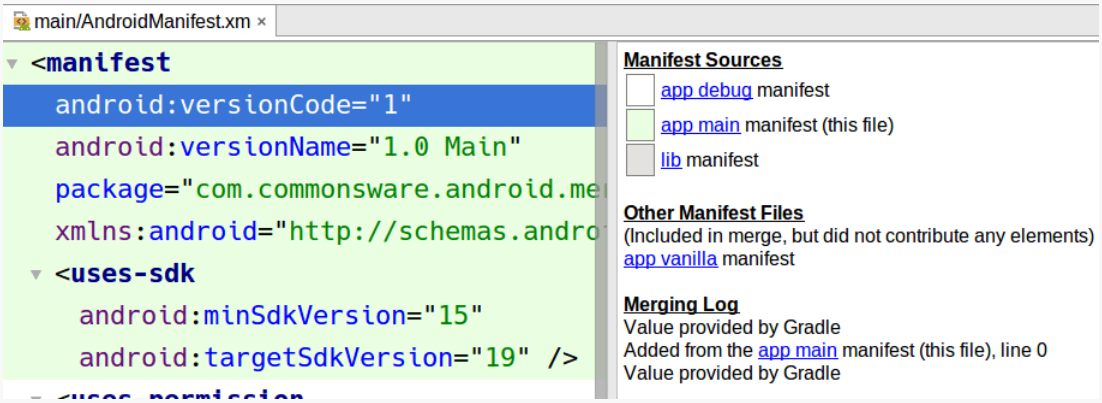

Figure 333: Merged Manifest View, Showing Merged Values from Gradle

Example #2: Additional Permissions

The `debug/` version of the manifest has a `<uses-permission>` element:

```
<uses-permission android:name="android.permission.WRITE_EXTERNAL_STORAGE" />
```

So does the `vanilla/` version, though its has `android:maxSdkVersion` set to 18:

```
<uses-permission
  android:name="android.permission.WRITE_EXTERNAL_STORAGE"
  android:maxSdkVersion="18"/>
```

The manifest you get from a `vanilla` debug build has the `android:maxSdkVersion` attribute:

```
<uses-permission
  android:name="android.permission.WRITE_EXTERNAL_STORAGE"
  android:maxSdkVersion="18" />
```

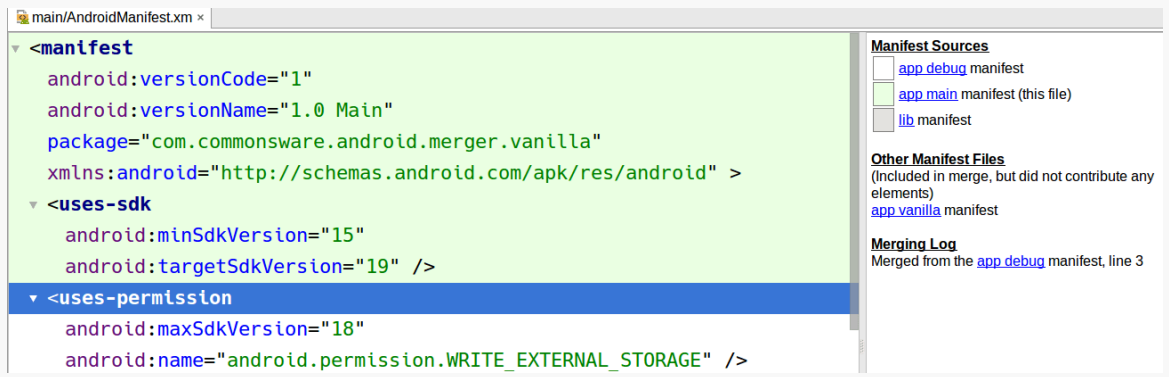

Figure 334: Merged Manifest View, Showing Merged Element

Example #3: Additional Components

The `lib/` version of the manifest has an `<activity>`:

```
<activity android:name="ThisActivityDoesNotExist">
  <intent-filter>
    <action android:name="com.commonsware.android.merger.lib.SOMETHING_COOL" />
    <category android:name="android.intent.category.DEFAULT" />
  </intent-filter>
</activity>
```

This is contributed by the library (or would be, if there actually was source code for the activity...). Neither the `main/` nor the `debug/` source set defines it, and so it is included verbatim in the result for `chocolate` builds:

```
<activity android:name="com.commonsware.android.merger.lib.ThisActivityDoesNotExist" >
  <intent-filter>
    <action android:name="com.commonsware.android.merger.lib.SOMETHING_COOL" />

    <category android:name="android.intent.category.DEFAULT" />
  </intent-filter>
</activity>
```

Note that since the `android:name` attribute had a bare class name, the generated manifest expands that to include the *library's* package name (`com.commonsware.android.merger.lib`). Note that this is the package name defined in `AndroidManifest.xml` — you cannot have an `applicationId` in `build.gradle` for a library project.

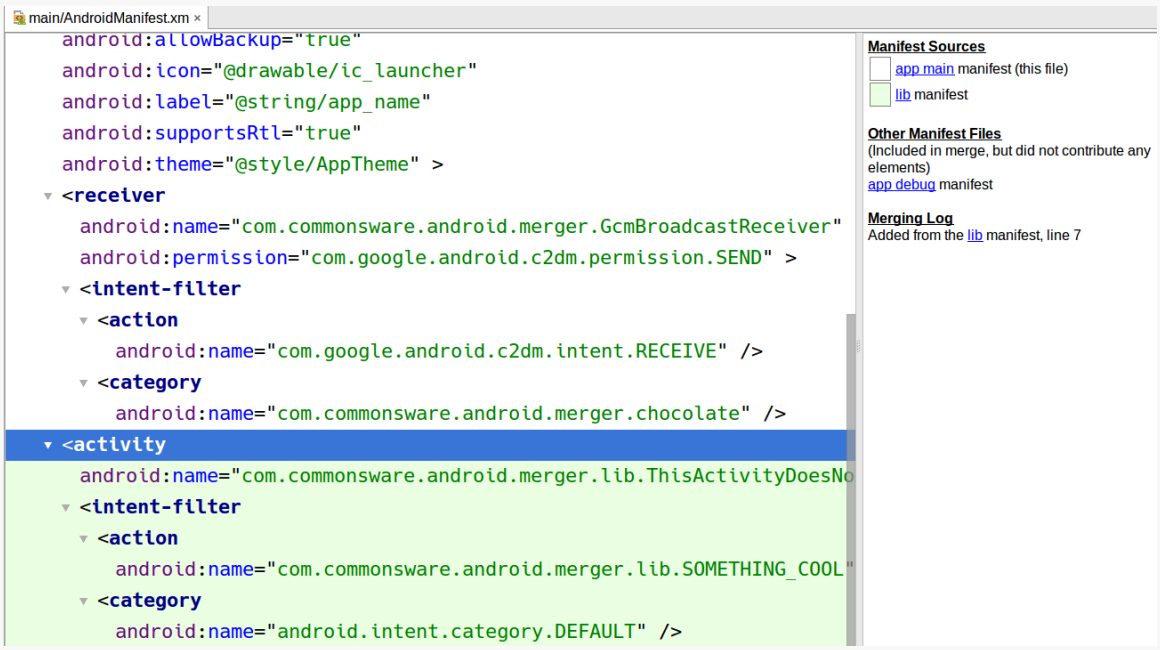

Figure 335: Merged Manifest View, Showing Merged Element

Example #4: Intent Filter

However, the `vanilla/` manifest also defines the same activity, this time with another `<intent-filter>`:

```
<activity android:name="com.commonsware.android.merger.lib.ThisActivityDoesNotExist">
  <intent-filter>
    <action android:name="com.commonsware.android.merger.SOMETHING_VANILLA" />
    <category android:name="android.intent.category.DEFAULT" />
  </intent-filter>
</activity>
```

Note that here, we need to have the fully-qualified class name, as we are trying to affect the library-supplied activity.

In a `vanilla` build, *both* `<intent-filter>` elements will be included by default:

```
<activity android:name="com.commonsware.android.merger.lib.ThisActivityDoesNotExist" >
  <intent-filter>
    <action android:name="com.commonsware.android.merger.SOMETHING_VANILLA" />

    <category android:name="android.intent.category.DEFAULT" />
  </intent-filter>
```

```
  <intent-filter>
    <action android:name="com.commonsware.android.merger.lib.SOMETHING_COOL" />

    <category android:name="android.intent.category.DEFAULT" />
  </intent-filter>
</activity>
```

This allows an app developer to add new ways of accessing an activity (or other component) exposed by a library.

However, the merged manifest view may not necessarily indicate where the elements came from properly:

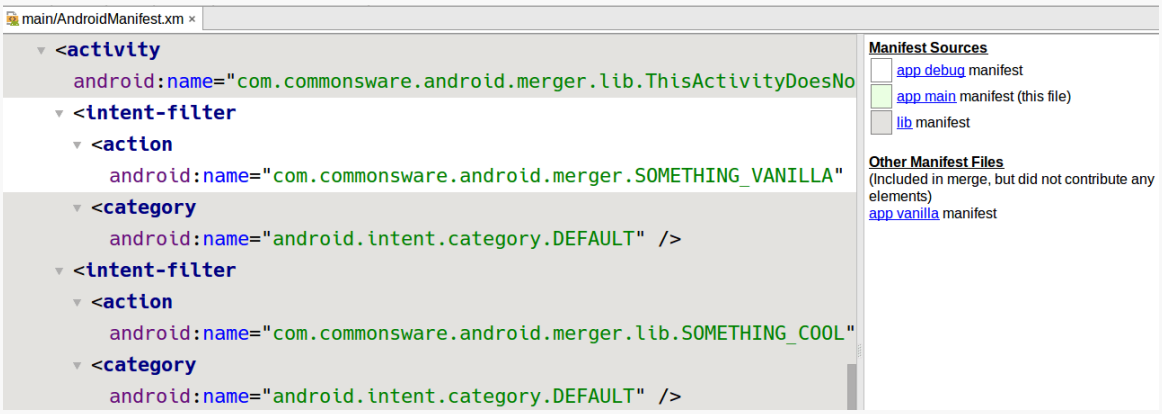

Figure 336: Merged Manifest View, Showing Merged Element

Some Unusual Scenarios

Not everything fits the neat-and-tidy rules from the above sections and require special explanation.

uses-sdk

The `android:minSdkVersion` and `android:targetSdkVersion` from the highest-priority manifest will be used. If, however, a library's manifest specifies higher values for `minSdkVersion`, you will get a build error.

Hence, it is incumbent upon library authors to correctly assess how old a version of Android they are able to support, setting `android:minSdkVersion` as low as possible.

Conversely, library authors should aim to support either old or new behavior that is controlled by `android:targetSdkVersion`. For example, a library that uses `AsyncTask` should not assume that the `android:targetSdkVersion` is below 13 and therefore `execute()` will result in multi-threaded behavior on Android 3.2+. Instead, the library should use `executeOnExecutor()` on API Level 11+ devices, to specifically opt into the multi-thread thread pool, as this avoids any behavior changes based upon `android:targetSdkVersion`.

uses-feature and uses-library

The `android:required` attribute is logically OR'd among all contributors of a `<uses-feature>` element for a specific `android:name` value. In other words, if any contributor says that the feature is required, it is required. Otherwise, if one or more contributors ask for the `<uses-feature>` element but say that it is not required, it is put in the combined manifest with `android:required="false"`.

The under-utilized `<uses-library>` uses the same rule for handling the merger of its `android:required` attribute.

Markers and Selectors

Sometimes, the default merger rules will not work to your satisfaction. In particular, when there are conflicts, the build will fail, and probably that is not a desired outcome.

To declare who wins in the case of conflicts, you can use `tools:*` attributes in the manifest elements. Specifically:

- `tools:node` indicates how to resolve a conflict between two editions of this particular XML element (e.g., an `<activity>` for the same `android:name`)
- `tools:replace` indicates that certain attributes from a lower-priority edition of the manifest should be overwritten by their replacement values from a higher-priority edition of the manifest
- `tools:remove` indicates that certain attributes from a lower-priority edition of the manifest should be removed entirely

Each of these, being in the `tools` namespace, will require you to have `xmlns:tools="http://schemas.android.com/tools"` on the root `<manifest>` element, if it is not there already. These attributes only affect the build tools and

have no runtime implications, other than in terms of how the build tools build your app based on the `tools` attributes.

For example, the main manifest has `android:supportsRtl="true"` on the `<application>` element:

```
<application android:allowBackup="true"
  android:label="@string/app_name"
  android:icon="@drawable/ic_launcher"
  android:theme="@style/AppTheme"
  android:supportsRtl="true">

  // other stuff here

</application>
```

For a project with a `targetSdkVersion` of 17 or higher, `android:supportsRtl="true"` enables automatic mirroring support for your layouts for right-to-left (RTL) languages.

The vanilla manifest wants to override this, replacing the value with `false`, as perhaps the code in that flavor is not yet ready for automatic mirroring. However, if the vanilla manifest just had `android:supportsRtl="false"` in its `<application>` element, the build would fail, as that value conflicts with the one in the main manifest. Hence, the vanilla manifest also needs to indicate that its `android:supportsRtl` value should replace the original one, via a `tools:replace` attribute:

```
<application android:allowBackup="true"
  android:label="@string/app_name"
  android:icon="@drawable/ic_launcher"
  android:theme="@style/AppTheme"
  android:supportsRtl="false"
  tools:replace="android:supportsRtl">

  // other stuff here

</application>
```

In the output, `android:supportsRtl="false"` wins:

```
<application
  android:allowBackup="true"
  android:icon="@drawable/ic_launcher"
```

```
  android:label="@string/app_name"
  android:theme="@style/AppTheme"
  android:supportsRtl="false" >

  // other stuff here

</application>
```

Both `tools:replace` and `tools:remove` take a comma-delimited list of attributes that should be affected by that rule.

Once again, the merged manifest view may not indicate the source of the attribute properly:

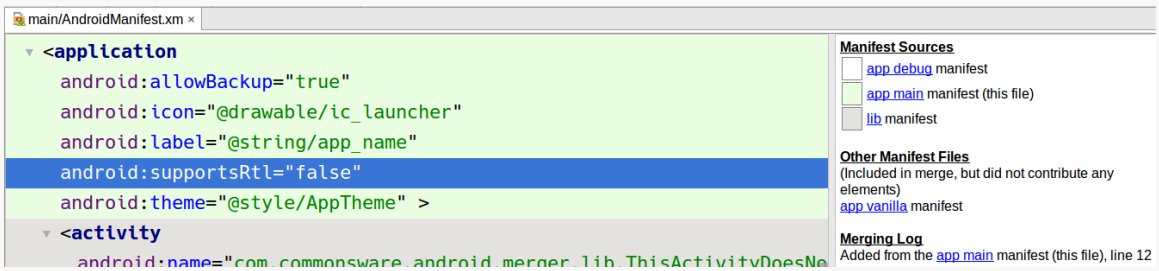

Figure 337: Merged Manifest View, Showing Merged Attribute

The `tools:node` attribute affects the entire XML element in which it resides. There are five primary values for `tools:node`:

1. `merge`, which is the default behavior described by the merger rules earlier in this chapter
2. `replace` says that the lower-priority manifest's version of this element should be replaced in its entirety with the higher-priority manifest's version of this element
3. `merge-only-attributes` says that the lower-priority manifest's version of this element should have its attributes replaced by the ones from the higher-priority manifest's version of this element, but child elements (e.g., an `<intent-filter>` underneath the annotated `<activity>` element) are left alone
4. `remove` says that the lower-priority manifest's version of this element should be removed without any replacement
5. `removeAll` says that all elements of this name (e.g., `<uses-permission>`) from lower-priority manifests should be removed, regardless of scopes like `android:name`

There is also a `strict` value that indicates that any duplication, even if it could be successfully merged, should result in a build failure. Most likely, this would be used sparingly.

By default, these `tools` attributes affect all manifests. However, it could be that you only want to affect a specific manifest, such as one coming from a certain library. In that case, `tools:selector`, in the same XML element as the other `tools:*` attributes, provides the package name of the library that the other `tools:*` attributes affect.

Employing Placeholders

The Google Cloud Messaging (GCM) system has some unusual requirements for the manifest of apps that use GCM:

- The app needs to define a custom permission, based on the application ID, via a `<permission>`
- The app needs to hold that custom permission, via a `<uses-permission>` element
- The app needs to have a `BroadcastReceiver` whose `<intent-filter>` has a `<category>` whose name is the application ID

Hence, in a GCM client app's manifest, there are three places where the application ID needs to appear. This needs to be the app's actual application ID, as may be defined either via manifests or via `applicationId` or `applicationIdSuffix` statements in a `build.gradle` file. Since the application ID can be overridden by those Gradle statements, we cannot just hard-code the application ID into the spots in the manifest.

Fortunately, part of what we get with manifest generation are placeholders.

Placeholders allow us to inject values from `build.gradle` into the manifest, particularly in XML attribute values. An `applicationId` placeholder is available automatically, and we can define custom ones via a `manifestPlaceholders` map.

For example, the main manifest for the sample project uses the `applicationId` placeholder in the requisite locations:

```
<manifest xmlns:android="http://schemas.android.com/apk/res/android"
    package="com.commonsware.android.merger"
    android:versionName="1.0 Main">
```

```
    <permission android:name="${applicationId}.C2D_MESSAGE"
        android:protectionLevel="signature" />
    <uses-permission android:name="${applicationId}.C2D_MESSAGE" />

    <application android:allowBackup="true"
        android:label="@string/app_name"
        android:icon="@drawable/ic_launcher"
        android:theme="@style/AppTheme"
        android:supportsRtl="true">
      <receiver
        android:name=".GcmBroadcastReceiver"
        android:permission="com.google.android.c2dm.permission.SEND" >
        <intent-filter>
          <action android:name="com.google.android.c2dm.intent.RECEIVE" />
          <category android:name="${applicationId}" />
        </intent-filter>
      </receiver>
    </application>

</manifest>
```

The vanilla debug version of the generated manifest replaces those `${applicationId}` placeholders with the actual `applicationId`, such as the following for a `vanilla` build:

```
<?xml version="1.0" encoding="utf-8"?>
<manifest xmlns:android="http://schemas.android.com/apk/res/android"
  package="com.commonsware.android.merger.vanilla"
  android:versionCode="1"
  android:versionName="1.0 Main" >

  <uses-sdk
    android:minSdkVersion="15"
    android:targetSdkVersion="19" />

  <uses-permission
    android:name="android.permission.WRITE_EXTERNAL_STORAGE"
    android:maxSdkVersion="18" />

  <permission
    android:name="com.commonsware.android.merger.vanilla.C2D_MESSAGE"
    android:protectionLevel="signature" />

  <uses-permission android:name="com.commonsware.android.merger.vanilla.C2D_MESSAGE"
/>
```

```
  <application
    android:allowBackup="true"
    android:icon="@drawable/ic_launcher"
    android:label="@string/app_name"
    android:theme="@style/AppTheme"
    android:supportsRtl="false" >
    <activity
android:name="com.commonsware.android.merger.lib.ThisActivityDoesNotExist" >
      <intent-filter>
        <action android:name="com.commonsware.android.merger.SOMETHING_VANILLA" />

        <category android:name="android.intent.category.DEFAULT" />
      </intent-filter>
      <intent-filter>
        <action android:name="com.commonsware.android.merger.lib.SOMETHING_COOL" />

        <category android:name="android.intent.category.DEFAULT" />
      </intent-filter>
    </activity>

    <receiver
      android:name="com.commonsware.android.merger.GcmBroadcastReceiver"
      android:permission="com.google.android.c2dm.permission.SEND" >
      <intent-filter>
        <action android:name="com.google.android.c2dm.intent.RECEIVE" />

        <category android:name="com.commonsware.android.merger.vanilla" />
      </intent-filter>
    </receiver>
  </application>

</manifest>
```

Note that the entire XML attribute value does not have to be a placeholder. For example, the `android:name` values for the `<permission>` and `<uses-permission>` elements blend the `applicationId` in with a fixed string: `android:name="${applicationId}.C2D_MESSAGE"`.

If you want additional placeholders, you can define a `manifestPlaceholders` map in `defaultConfig` or in a product flavor:

```
android {
  defaultConfig {
    manifestPlaceholders = [ foo: "bar"]
  }
```

```
  productFlavors {
    vanilla {
    }

    chocolate {
      manifestPlaceholders = [ foo: "baz" ]
    }
  }
}
```

Then, you can refer to any of your custom placeholders via the same `${}` syntax (e.g., `${foo}`, with the proper value being applied during manifest generation.

Signing Your App

Perhaps the most important step in preparing your application for production distribution is signing it with a production signing key. While mistakes here may not be immediately apparent, they can have significant long-term impacts, particularly when it comes time for you to distribute an update.

Prerequisites

Understanding this chapter requires that you have read the core chapters of this book.

Role of Code Signing

There are many reasons why Android wants you to sign your application with a production key. Here are perhaps the top three:

- It will help distinguish your production applications from debug versions of the same applications
- Multiple applications signed with the same key can access each other's private files, if they are set up to use a shared user ID in their manifests
- You can only update an application if it has a signature from the same digital certificate

The latter one is the most important for you, if you plan on offering updates of your application. If you sign version 1.0 of your application with one key, and you sign version 2.0 of your application with another key, version 2.0 will not install over the top of version 1.0 — it will fail with a certificate-match error.

What Happens In Debug Mode

Of course, you may be wondering how you got this far in life without worrying about keys and certificates and signatures (unless you are using Google Maps, in which case you experienced a bit of this when you got your API key).

The Android build process creates a debug key for you automatically. That key is automatically applied when you create a debug version of your application (e.g., running the app in your IDE). This all happens behind the scenes, so it is very possible for you to go through weeks and months of development and not encounter this problem.

In fact, the most likely place where you might encounter this problem is in a distributed development environment, such as an open source project. There, you might have encountered the third bullet above, where a debug application compiled by one team member cannot install over the debug application from another team member, since they do not share a common debug key. You may have run into similar problems just on your own if you use multiple development machines (e.g., a desktop in the home office and a notebook for when you are on the road delivering Android developer training).

Finding Your Debug Keystore

The debug keystore is a `debug.keystore` file in your Android SDK data directory. This directory is not where your SDK is installed, but rather is where the tools store data unique to your account on your developer machine, such as your emulator AVDs.

This directory can be found at:

- `~/.android/` on macOS and Linux
- `C:\Documents and Settings\...\.android\` on Windows XP
- `C:\Users\...\.android\` on Windows environments newer than XP

(where `...` is your Windows username)

Synchronizing Your Debug Signing Key

If you have a development team that, for better coordination, should all use the same `debug.keystore`, just pick one and copy it to all team members' development

machines, replacing their generated ones. The `debug.keystore` file is a binary file and should be transferable between operating systems (e.g., from Linux to Windows).

Production Signing Keys

Beyond the debug keystore, though, you will need one for production use. Distribution channels like the Play Store do not accept apps signed with the debug signing key. So, you will need to create a key that *is* acceptable to those channels, plus arrange to use that key when creating your production apps.

How long your production signing key is valid for is important. Once your key expires, you can no longer use it for signing new applications, which means once the key expires, you cannot update existing Android applications. Also, the Play Store requires your key to be valid beyond October 22, 2033. When you create your key, you will indicate how long it should be valid for.

Note that both the debug signing key and its production counterpart are self-signed certificates — you do not have to purchase a certificate from Verisign or anyone. These keys are for creating immutable identity, but are not for creating confirmed identity. In other words, these certificates do not prove you are such-and-so person, but can prove that the same key signed two different APKs.

Creating a Production Signing Key

The mechanics of creating a production signing key depend on whether you will use an IDE (and, if so, which one) or will create one outside of any IDE.

Android Studio

Android Studio has support to create a production signing key as part of its overall process for creating a production-signed APK, which is covered later in this chapter.

Manually

To manually create a production signing key, you will need to use `keytool`. This comes with the Java SDK, and so it should be available to you already.

The `keytool` utility manages the contents of a “keystore”, which can contain one or more keys. Each “keystore” has a password for the store itself, and keys can also have

their own individual passwords. You will need to supply these passwords later on when signing an application with the key.

Here is an example of running keytool:

```
keytool -genkey -v -keystore cw-release.keystore -alias cw-release -keyalg RSA
-validity 10000 -keysize 2048
```

The parameters used here are:

1. `-genkey`, to indicate we want to create a new key
2. `-v`, to be verbose about the key creation process
3. `-keystore`, to indicate what keystore we are manipulating (`cw-release.keystore`), which will be created if it does not already exist
4. `-alias`, to indicate what human-readable name we want to give the key (`cw-release`)
5. `-keyalg`, to indicate what public-key encryption algorithm to be using for this key (`RSA`)
6. `-validity`, to indicate how long this key should be valid, where 10,000 days or more is recommended
7. `-keysize`, for indicating the length of the signing key (2,048 bits recommended, or go higher if you prefer)

If you run the above command, you will be prompted for a number of pieces of information. If you have ever created an SSL certificate, the prompts will be familiar:

```
$ keytool -genkey -v -keystore cw-release.keystore -alias cw-release -keyalg RSA
-validity 10000 -keysize 2048
Enter keystore password:
Re-enter new password:
What is your first and last name?
  [Unknown]:  Mark Murphy
What is the name of your organizational unit?
  [Unknown]:
What is the name of your organization?
  [Unknown]:  CommonsWare, LLC
What is the name of your City or Locality?
  [Unknown]:
What is the name of your State or Province?
  [Unknown]:  PA
What is the two-letter country code for this unit?
  [Unknown]:  US
Is CN=Mark Murphy, OU=Unknown, O="CommonsWare, LLC", L=Unknown, ST=PA, C=US correct?
  [no]:  yes
```

```
Generating 2,048 bit RSA key pair and self-signed certificate (SHA256withRSA) with a
validity of 10,000 days
  for: CN=Mark Murphy, OU=Unknown, O="CommonsWare, LLC", L=Unknown, ST=PA, C=US
Enter key password for <cw-release>
  (RETURN if same as keystore password):
[Storing cw-release.keystore]
```

Signing with the Production Key

How you will apply this production signing key to sign your production app again varies by your tool chain.

Android Studio

Start by opening up your project and going to Build > Generate Signed APK from the main menu. This brings up the first page of a signing wizard:

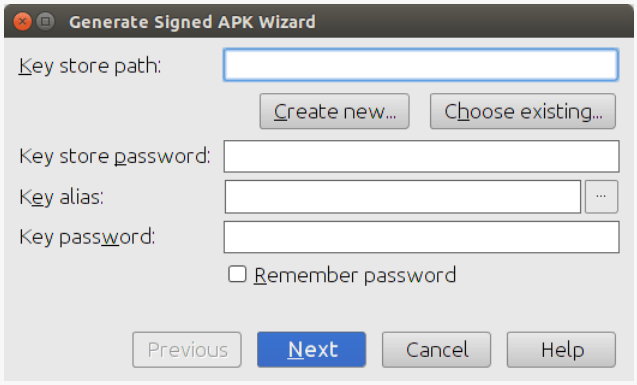

Figure 338: Android Studio Generate Signed APK Wizard, First Page

If this is the first time you are going to sign a production app, you will need to create your production signing key, which you can do by clicking the "Create new..." button in the wizard. This brings up a separate dialog for describing the new signing key:

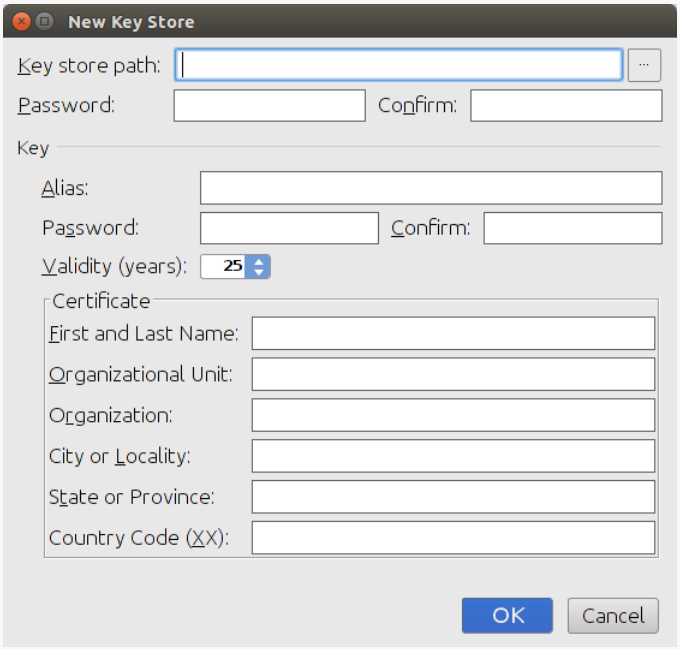

Figure 339: Android Studio New Key Store Dialog

You will need to provide a path to the keystore, manually or via the "..." button to pick a location via a dialog. You will also need to provide a password (twice) for the keystore.

You can then supply information for the signing key within the keystore, including:

- "Alias" to indicate what human-readable name we want to give the key
- "Password" and "Confirm", to specify a password for this specific key in the keystore (independent of the keystore's own password)
- "Validity", to indicate how long this key should be valid, where 25 years or more is recommended
- Details about you and your organization, asking for the standard information used in generating SSL-style keys

Clicking "OK" will generate the keystore and save it where you specified. **Be sure to back up this keystore** and record the passwords that you used.

If you already have a keystore, though, back on the first page of the "Generate Signed APK" wizard, you can click "Choose existing" to bring up a file-open dialog where you can choose your keystore. Then, fill in the keystore password, the key alias, and the key password in the dialog.

Clicking Next in the wizard brings up a page allowing you to determine what will be generated:

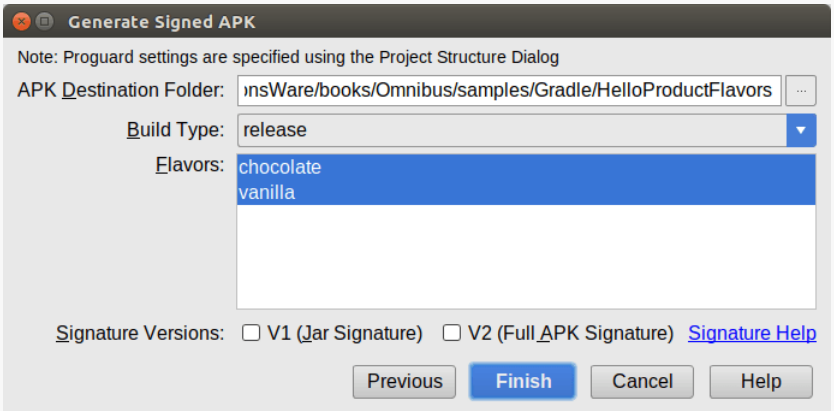

Figure 340: Android Studio Generate Signed APK Wizard, Second Page

You can indicate where the APK file should be written, what build type to use (`release` being the default), and which product flavors to use (where you can select one or several).

You can also choose which signature versions that you want to use. You have two options:

1. V1, which is the way APKs have been signed since Android 1.0
2. V2, which is an improved signature format, offering stronger protection and faster app installs, but only works on Android 7.0+

Ideally, check both signature versions. If for some reason the V2 signature format causes build problems, uncheck that version and only use V1.

Clicking "Finish" will have Android Studio begin generating the APK files. This may take some time. When it is done, a dialog will appear indicating that the work is completed. In the directory that you specified, you will get one APK file per product flavor you chose, plus manifest merger reports for those APK files. And, of course, the APK files will be signed with your chosen keystore and signing key.

Gradle

The Android Gradle Plugin can also be used to sign a production app. Curiously, this is completely independent of the mechanism that Android Studio uses to sign a

production app. Filling in the dialogs in Android Studio does not affect your `build.gradle` file, and Android Studio's "Generate Signed APK" completely ignores any manual signing configuration that you may set up in `build.gradle` (and is discussed in this section). What is covered in this section focuses on automating the signing process, to be done via a build server or just running a Gradle task from the command line.

To be able to use the Android Gradle Plugin to sign your production app, you need to provide a signing configuration to the `release` build type:

```
apply plugin: 'com.android.application'

dependencies {
    implementation 'com.squareup.picasso:picasso:2.5.2'
    implementation 'com.squareup.retrofit2:converter-gson:2.1.0'
}

android {
    compileSdkVersion 25
    buildToolsVersion '26.0.2'

    defaultConfig {
        versionCode 1
        versionName "1.0"
        minSdkVersion 15
        targetSdkVersion 25
    }

    signingConfigs {
        release {
            storeFile file('DebugActivity.keystore')
            keyAlias 'HelloConfig'
            storePassword 'laser.yams.heady.testy'
            keyPassword 'fw.stabs.steady.wool'
        }
    }

    buildTypes {
        debug {
            applicationIdSuffix ".d"
        }

        release {
            signingConfig signingConfigs.release
        }
```

```
    }
}
```

(from Diagnostics/Activity/app/build.gradle)

Here, our `release` build type has a `signingConfig` property, referencing the name of a signing configuration specified in the `signingConfigs` closure. This is used to provide rules for how to sign the APK that is assembled by Gradle. In this project's `build.gradle` file, we have a `release` closure in `signingConfigs`, supplying the requisite information about the keystore:

- The `storeFile` path, specified as a `file()` pointing to a keystore in the project's root directory
- The `keyAlias` given to the signing key inside the keystore
- The `storePassword` and `keyPassword` used to access the keystore

The `signingConfig` property in the `release` closure in `buildTypes` references the signing configuration we want as `signingConfigs.release`. All of these Groovy closures of properties in the `build.gradle` file are effectively building up a data structure, which we can access. So, `signingConfigs.release` says to find the `release` definition in the `signingConfigs` closure.

This sample bakes in the keystore data into the `build.gradle` file, including the passwords, and has the keystore in the root of the project. That is for demonstration simplicity and will not be suitable for all projects. In particular, keystores and their credentials should *not* be stored in a publicly accessible repository, as that would allow others to sign *their* apps with *your* signing key, which is not good. There are a variety of strategies for handling this, from using environment variables to requesting the data be entered on the command line, as are discussed in the chapter on advanced Gradle techniques.

Adding a `signingConfig` property in our `release` build type enables the `installRelease` task. Running `gradle tasks` will show `installRelease` as an available option, because now the Android Gradle Plugin knows how to sign the APK. Of course, there could be flaws in the signing configuration (e.g., mis-entered key alias), and that will result in build errors when you try to `installRelease` the project.

Two Types of Key Security

There are two facets to securing your production key that you need to think about:

- You need to make sure nobody steals your production keystore and its password. If somebody does, they could publish replacement versions of your applications — since they are signed with the same key, Android will assume the replacements are legitimate.
- You need to make sure you do not lose your production keystore and its password. Otherwise, even *you* will be unable to publish replacement versions of your applications.

For solo developers, the latter scenario is more probable. There already have been **many** cases where developers had to rebuild their development machine and wound up with new keys, locking themselves out from updating their own applications. As with everything involving computers, having a solid backup regimen is highly recommended. In particular, consider a secure off-site backup, such as having your production keystore on a thumb drive in a bank safe deposit box.

For teams, the former scenario may be more likely. If more than one person needs to be able to sign the application, the production keystore will need to be shared, possibly even stored in the revision control system for the project. The more people who have access to the keystore, the more likely it is somebody will wind up doing something evil with it. This is particularly true for projects with public revision control systems, such as open source projects — developers might not think of the implications of putting the production keystore out for people to access.

Distribution

It is entirely possible that the user base for your app consists solely of yourself.

However, in most cases, you are going to be giving your app to others, free or for some sort of fee.

This chapter outlines things you will need to think about when distributing your app.

Prerequisites

Understanding this chapter requires that you have read the core chapters of this book, particularly the chapter on signing your app.

Get Ready To Go To Market

While being able to sign your application reliably with a production key is necessary for publishing a production application, it is not sufficient. Particularly for the Play Store, there are other things you must do, or should do, as part of getting ready to release your application.

Versioning

You need to supply `versionCode` and `versionName` values in your `build.gradle` file. The value of `versionName` is what users and prospective users will see in terms of the label associated with your application version (e.g., "1.0.1", "System V", "Loquacious Llama"). More important, though, is the value of `versionCode`, which needs to be an

integer increasing with each release — that is how Android tells whether some edition of your APK is an upgrade over what the user currently has.

Application ID

You also need to make sure that your application ID is going to be unique. If somebody tries downloading your application onto their device, and some other application is already installed with that same package name, your application will fail to install.

Your application ID defaults to be the value of your `package` attribute in your `<manifest>` element in the manifest. You can override the application ID using `applicationId` properties in `defaultConfig` or a product flavor in `build.gradle`. You can also append an `applicationIdSuffix` tied to a build type or product flavor in Gradle as well.

Since the manifest's `package` also provides the base Java package for your project, and since you hopefully named your Java packages with something based on a domain name you own or something else demonstrably unique, this should not cause a huge problem.

Also, bear in mind that your application ID must be unique across all applications on the Play Store, should you choose to distribute that way.

Icon and Label

Your `<application>` element needs to specify `android:icon` and `android:label` attributes, to supply the display name and icon that will be associated with the application in the My Applications list on the device and related screens. Your activities will inherit the icon if they do not specify icons of their own.

If you have graphic design skills, the Android developer site has guidelines for creating icons that will match other icons in the system.

Logging

In production, try to minimize unnecessary logging, particularly at low logging levels (e.g., debug). Remember that even if Android does not actually log the information, whatever processing is involved in making the `Log.d()` call will still be

done, unless you arrange to skip the processing somehow. You could outright delete the extraneous logging calls, or wrap them in an `if()` test:

```
if (BuildConfig.DEBUG) {
  Log.d(TAG, "This is what happened");
}
```

Here, `BuildConfig.DEBUG` is a `public static final boolean` value, supplied by Android, that indicates whether you are building for debug or production. Whether you adjust the definition by hand or by automating the build process is up to you. But, when `BuildConfig.DEBUG` is `false`, any work that would have been done to build up the actual `Log` invocation will be skipped, saving CPU cycles and battery life.

Conversely, error logs become even more important in production. Sometimes, you have difficulty reproducing bugs "in the lab" and only encounter them on customer devices. Being able to get stack traces from those devices could make a major difference in your ability to get the bug fixed rapidly.

First, in addition to your regular exception handlers, consider catching everything those handlers miss, notably runtime exceptions:

```
Thread.setDefaultUncaughtExceptionHandler(onBlooey);
```

This will route all uncaught exceptions to an `onBlooey` handler:

```
private Thread.UncaughtExceptionHandler onBlooey=
  new Thread.UncaughtExceptionHandler() {
  public void uncaughtException(Thread thread, Throwable ex) {
    Log.e(TAG, "Uncaught exception", ex);
  }
};
```

There, you can log it, raise a dialog if appropriate, etc.

Then, offer some means to get your logs off the device and to you, via email or a Web service. Some Android analytics firms, like Flurry, offer exception stack trace collection as part of their service. There are also open source projects that support this feature, such as ACRA.

Testing

As always, testing, particularly acceptance testing, is important.

Bear in mind that the act of creating the production signed version of your application could introduce errors, such as having the wrong Google Maps V2 API key. Hence, it is important to do user-level testing of your application after you sign, not just before you sign, in case the act of signing messed things up. After all, what you are shipping to those users is the production signed edition — you do not want your users tripping over obvious flaws.

As you head towards production, also consider testing in as many distinct environments as possible, such as:

1. Trying more than one device, particularly if you can get devices with different display sizes
2. If you rely on the Internet, try your application with WiFi, with 3G, with EDGE/2G, and with the Internet unavailable
3. If you rely on GPS, try your application with GPS disabled, GPS enabled and working, and GPS enabled but not available (e.g., underground)

EULA

End-user license agreements — EULAs — are those long bits of legal prose you are supposed to read and accept before using an application, Web site, or other protected item. Whether EULAs are enforceable in your jurisdiction is between you and your qualified legal counsel to determine.

In fact, many developers, particularly of free or open source applications, specifically elect not to put a EULA in their applications, considering them annoying, pointless, or otherwise bad.

However, the Play Store developer distribution agreement has one particular clause that might steer you towards having a EULA:

> You agree that if you use the Store to distribute Products, you will protect the privacy and legal rights of users. If the users provide you with, or your Product accesses or uses, user names, passwords, or other login information or personal information, you must make the users aware that the information will be available to your Product, and you must provide legally adequate privacy notice and protection for those users. Further, your

> Product may only use that information for the limited purposes for which the user has given you permission to do so. If your Product stores personal or sensitive information provided by users, it must do so securely and only for as long as it is needed. But if the user has opted into a separate agreement with you that allows you or your Product to store or use personal or sensitive information directly related to your Product (not including other products or applications) then the terms of that separate agreement will govern your use of such information. If the user provides your Product with Google Account information, your Product may only use that information to access the user's Google Account when, and for the limited purposes for which, the user has given you permission to do so.

Hence, if you are concerned about being bound by what Google thinks appropriate privacy is, you may wish to consider a EULA just to replace their terms with your own.

Unfortunately, having a EULA on a mobile device is particularly annoying to users, because EULAs tend to be long and screens tend to be short.

Again, please seek professional legal assistance on issues regarding EULAs.

Writing a Gradle Plugin

Gradle is very extensible, from Groovy scripting code in your `build.gradle` file all the way up to dedicated Gradle plugins. The more you want to reuse a particular piece of functionality, or the more sophistication you want in your custom builds, the more likely it is that a Gradle plugin will be the right solution.

Sometimes, a Gradle plugin will be focused mostly on tailoring the build process itself. However, a Gradle plugin could be simply an integration point for a tool that could be used in other ways (e.g., command-line API) that would not otherwise require Gradle. This is particularly true for tools that work across IDEs, where you put most of the core logic into a core set of tool code and have thin build system plugins that bridge between the build system or IDE and the tool itself.

In this chapter, we will look at the basics of setting up a Gradle plugin. The plugin that we develop in this chapter will not do much of anything. The *next* chapter, however, creates a Gradle plugin that generates Java code, building on what we explore here.

Prerequisites

This chapter will make the most sense if you have read the preceding chapters on Gradle, particularly the chapter on Gradle tasks.

Customizing a Gradle Build

Gradle is Groovy — in other words, Gradle is a domain specific language (DSL) implemented in the Groovy scripting language. Hence, you are welcome to blend in Groovy code into your `build.gradle` file, for everything from simple string

concatenation to loops, branches, and everything else that you would expect from a modern OO-flavored scripting language.

You are not limited to putting that Groovy code directly in `build.gradle` either. You can use `apply from:` to indicate the path to some other Gradle script, reminiscent of a `#include` from C/C++, `<include>` elements in an Android layout resource, and so forth:

```
apply from: 'relative/path/to/some.gradle'
```

Or, you can create a `buildSrc/` directory in your project root. In there, you can have Java code (e.g., in `src/main/java/`) or Groovy code (e.g., in `src/main/groovy/`), all of which will be compiled and added to the classpath for your main `build.gradle` file. As a result, your `build.gradle` file can refer to whatever classes and such are created in this `buildSrc/` quasi-module. This is powerful, but it is inconvenient to distribute, except for other people working on the same overall project (e.g., via version control systems). As such, this approach is mostly for project-specific build system extensions.

A Gradle plugin is a separate module, akin to the `buildSrc/` directory, that creates a JAR that incorporates compiled Java and Groovy code. That plugin JAR can then be used by other modules or other projects. The plugin can be distributed through Maven Central, JCenter, or other artifact repositories. And, people can use it just like you use the Android Gradle Plugin: requesting it in a `buildscript` closure and applying the plugin. This is somewhat more complicated to set up than is a `buildSrc/` directory, but it offers the easiest path for distributing substantial build customizations.

Some Use Cases for a Custom Plugin

For lightweight tweaking of how a build is done, adding some Groovy code to your `build.gradle` file is the simplest solution. But sometimes what you want to do might get a bit involved for a smattering of lines in a `build.gradle` file, and it is these sorts of situations where a Gradle plugin becomes a useful approach.

Code Generation

Sometimes, we want to generate Java code based upon other sorts of files within our project.

The Android Gradle Plugin offers this sort of thing in a few of places:

- Our `R` class is code-generated by the `aapt` build tool, invoked through Gradle, based upon the contents of our resource directories
- The build tools similarly look for AIDL files — used in bound services — to code-generate our binding classes for us
- The data binding framework looks for layout files with a particular structure and code-generates some Java classes that implement data binding for the widgets in those layouts

Other developers do the same sort of thing. For example, Square has published the SQLDelight plugin, which code-generates a `SQLiteOpenHelper` subclass based upon a SQL script that you include in your module.

And, in the next chapter, we will see how to do this same sort of code generation.

Resource Generation

Sometimes, you want to generate other files, instead of Java. For example, Trello released the Victor Gradle plugin, which allows you to add SVG files to your module. Victor will convert those into PNGs or vector drawables for you automatically, rather than you having to do that yourself using various tools.

Code Analysis

Sometimes, we are not trying to create things, but instead are trying to analyze what is there and fail the build if the analysis turns up problems.

For example, a standard plugin distributed with Gradle integrates with the Checkstyle library to confirm that the source code adheres to coding standards.

Writing a Plugin

Creating a Gradle plugin is not especially difficult. It is somewhat esoteric and not especially well-documented, but this chapter hopefully will address those particular issues for you.

Create a Java Module

One major difference in creating a Gradle plugin versus creating an Android app is where the code runs. Android apps run on Android. Gradle plugins run on your development machine. As such, our code cannot use Android-specific APIs, so we need a module that knows about ordinary Java, not Android.

Android Studio's new-module wizard (New > New Module from the File menu) offers an option for "Java Library":

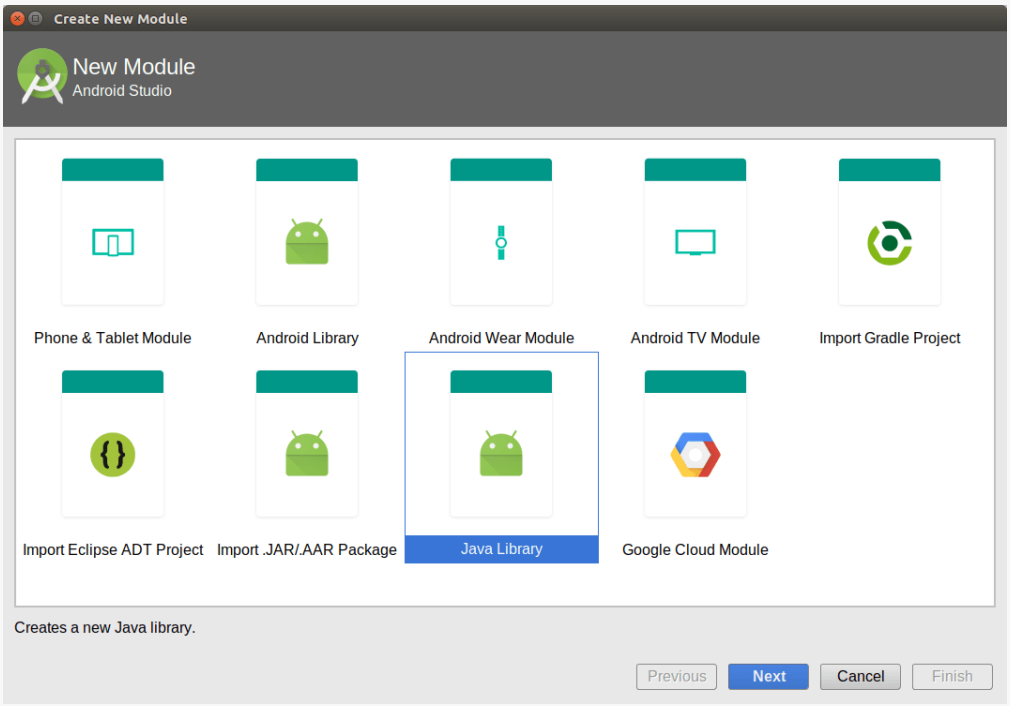

Figure 341: Android Studio New-Module Wizard, with Java Library Option

This will add a new module to the project, but one that uses the standard `java` Gradle plugin for building the code, rather than the `com.android.application` or `com.android.library` plugins used to create Android apps and libraries.

The second page of the new-module wizard asks some questions about the module to be created:

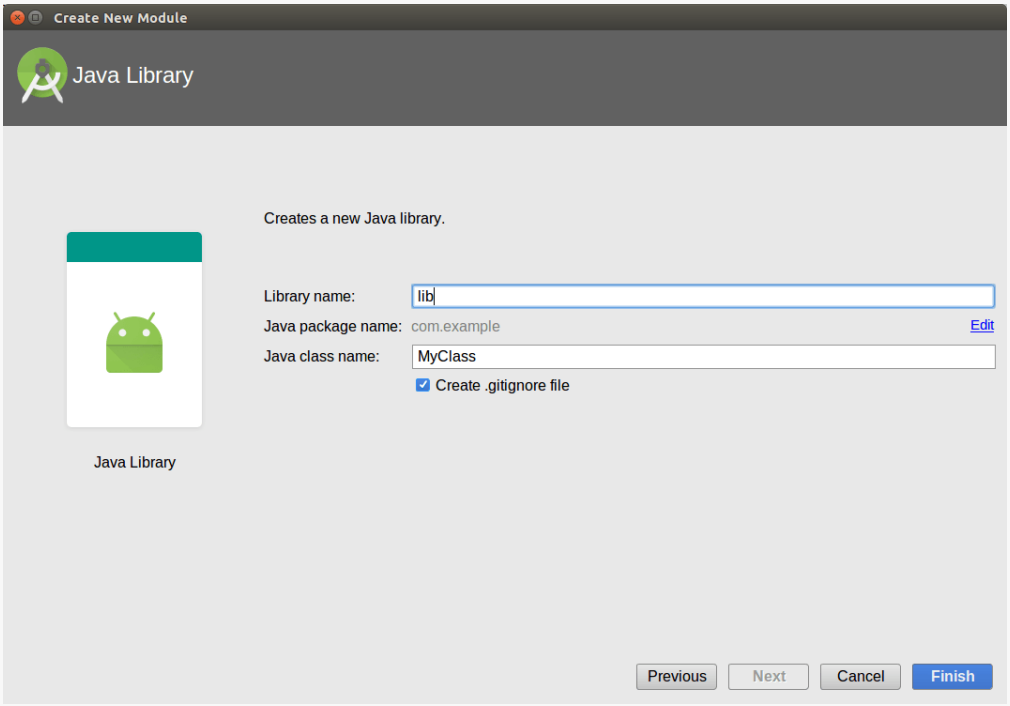

Figure 342: Android Studio New-Module Wizard, with Java Library Configuration

The big item is the "Library name", which will be the name of the module added to your project. If you are adding this to a large existing project — for example, adding a Gradle plugin to an existing tool – you might use `gradle-plugin` or something as the module name. If the project is creating a dedicated Gradle plugin, you might name the module after the plugin itself (e.g., the `staticizer` plugin that we will create in the next chapter). Or, you could take the approach used by the `Gradle/PluginStub` sample project, and call it `plugin`.

Creating a new Java library module forces you to create a Java class for use by the library. As you will see shortly, this is not a requirement for creating a Gradle plugin, though often you will wind up using Java classes along the way. You can choose the Java package name and class that makes the most sense for your code. There are no particular naming rules for Gradle plugins that you have to follow.

Apply the Groovy Plugin

The typical recipe for writing a Gradle plugin involves both Java code and Groovy code. That is not strictly required, as you could write the entire plugin in Java. For illustration purposes, the `PluginStub` sample project follows convention and uses Groovy along with Java.

However, an Android Studio-created Java module knows nothing about Groovy. It knows about Java, as the module's `build.gradle` file will have `apply plugin: 'java'` to teach Gradle that this module will contain Java code and create a Java JAR as output.

If you want to also use Groovy code, simply add `apply plugin: 'groovy'` to the module's `build.gradle` file:

```
apply plugin: 'groovy'
apply plugin: 'java'
```

(from Gradle/PluginStub/plugin/build.gradle)

Update the Dependencies

The plugin's module will also need some new dependencies:

```
dependencies {
    implementation gradleApi()
    implementation localGroovy()
}
```

(from Gradle/PluginStub/plugin/build.gradle)

The `gradleApi()` dependency pulls in Gradle's own internal API, for use by plugins. The `localGroovy()` dependency says that we can add a `src/main/groovy/` directory and put Groovy-defined Java classes in there, and they too will be added to the project.

Add a Groovy Source Directory and Package

Java classes defined in Groovy go into the same sort of Java package directory structure that regular Java classes do. It just so happens that they will reside under a `groovy/` directory, rather than a `java/` directory.

The `plugin/` module of the sample project has a `src/main/groovy/com/commonsware/android/gradle/plugin/` directory:

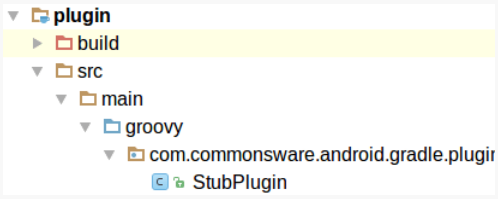

Figure 343: Android Studio, Showing Groovy Directory Structure

In there is a `StubPlugin.groovy` file containing some Groovy code.

Implement a Plugin

That code comes in the form of a `StubPlugin` class:

```
package com.commonsware.android.gradle.plugin

import org.gradle.api.Plugin
import org.gradle.api.Project

public class StubPlugin implements Plugin<Project> {
  @Override
  public void apply(Project target) {
    def myTask = target.tasks.create("stubTask") << {
      def helper = new StubHelper();
      println helper.getMessage();
    }

    myTask.group = "commonsware"
    myTask.description = "Do something useful"
  }
}
```

(from Gradle/PluginStub/plugin/src/main/groovy/com/commonsware/android/gradle/plugin/StubPlugin.groovy)

Again, this class could have been written in Java — there is nothing specific about plugin classes that requires Groovy. Groovy syntax for class definitions closely resembles that of Java.

Here, `StubPlugin` implements a `Plugin`, one creating a `Project`. Gradle plugins could be applied to other sorts of Gradle artifacts, at least in principle, though most samples you will see involve a `Project`. Here, `Project` refers to what Android Studio calls a module, and what Gradle itself refers to as a sub-project. In other words, the `Project` is a model object describing the actual app code that is being built, where our plugin can now interact with the build process.

The entry point into a `Plugin` is `apply()`, where you are given the build artifact (e.g., the `Project`), and your job is to tinker with the build process.

Gradle scripts are recipes for building an object model that, in turn, describes how to build a project. Similarly, what our plugin needs to do is *modify that recipe*, adding in hooks that will eventually get run during actual builds, where we can do special stuff.

A typical way of implementing this is to create one or more additional tasks, just like the tasks that Gradle itself has, or that the Android Plugin for Gradle adds. Here, we have Groovy code that defines a new task, named `stubTask`, being added to the roster of tasks for this `Project`. The Groovy code between the braces represents the work to be done by this Gradle task, and we will return to that code shortly.

The rest of `apply()` configures the rest of the task, putting it into a specific group (for use by Android Studio or other IDEs) and adding a description (for use with tooltips, generated documentation, and the like).

Using Both Groovy and Java

If you elect to use some amount of Groovy code with your plugin, the question then becomes: do you need Java at all, and if so, when?

In principle, Groovy can do everything that Java can. In practice, how much Groovy you want to write will depend largely on your comfort level with Groovy and with multi-language programming. You might elect to designate some in-app boundary as also serving as the boundary between programming languages. For example, you might say that plugin-specific code is written in Groovy, but code that is usable via other interfaces gets written in Java.

`StubPlugin` demonstrates integrating with ordinary Java code by means of the `StubHelper` instance that it creates and uses to retrieve a message (`getMessage()`), which `apply()` then dumps to the console via `println`. `StubHelper` is an ordinary Java class, in the `java/` peer set of directories to the `groovy/` directories. In particular, `StubHelper` happens to be in the same Java package as is `StubPlugin`, so we do not need an `import` statement for `StubHelper`. `StubHelper` itself is trivial, returning a static `String` as the result of `getMessage()`:

```
package com.commonsware.android.gradle.plugin;

public class StubHelper {
```

```
  String getMessage() {
    return("Hello, world!");
  }
}
```

(from Gradle/PluginStub/plugin/src/main/java/com/commonsware/android/gradle/plugin/StubHelper.java)

Adding Plugin Metadata

In an Android app, merely having Java classes inheriting from "magic" base classes like `Activity` or `Service` is insufficient. We also need to have some metadata to teach Android about our activities, services, and so on. In the case of an Android app, that metadata comes in the form of the manifest.

Similarly, we need to teach Gradle that:

- Our library contains one or more Gradle plugins
- What those Gradle plugins are called
- What Java/Groovy class is the entry point for the plugin

That is handled by its own form of metadata.

This metadata is held in a `resources/` directory inside of the `main/` source set. Here, `resources/` refers to classic Java resources, otherwise known as "semi-random files that wind up being stuffed into the JAR". It has little to do with *Android* resources that you might put in a `res/` directory in an Android project.

A typical convention for JARs is to have a `META-INF/` folder containing metadata. That is set up in a Java module by having a `resources/META-INF/` directory.

Gradle, in turn, wants to see a `gradle-plugins/` directory inside of `META-INF/`, with one or more `.properties` files. The base name of the `.properties` file (i.e., the name without the file extension) is the full name of the plugin. Convention nowadays is for third-party plugins to use Java-style reverse-domain-name names, like `com.android.application` and `com.android.library`. So, inside of `resources/META-INF/gradle-plugins/`, our Java module has `com.commonsware.android.gradle.plugin.properties`, to define a `com.commonsware.android.gradle.plugin` plugin.

The properties file needs only one line, defining the value for an `implementation-class` property. The value is the fully-qualified class name of the `Plugin` subclass that is the entry point for the plugin:

```
implementation-class=com.commonsware.android.gradle.plugin.StubPlugin
```

(from Gradle/PluginStub/plugin/src/main/resources/META-INF/gradle-plugins/com.commonsware.android.gradle.plugin.properties)

Distributing the Plugin

When you build the `plugin/` module, the result is a `plugin` JAR file located in `build/libs/` of the module. That JAR is what modules and projects that want to use the plugin need to access.

You could pass around the bare JAR file. Nowadays, the preferred approach for distributing JARs is to do so via artifacts in repositories, the way that we use such artifacts for libraries that we want to add to our Android apps. In fact, we have already seen one such plugin distributed via an artifact: the `com.android.tools.build:gradle` artifact that we reference in the `buildscript` `dependencies` closure in our top-level `build.gradle` file.

There are formal ways to publish artifacts to places like JCenter or Maven Central. For lightweight testing purposes, you can easily set up a Maven-style repository on your own development machine, as this sample app does. And there are "middle-ground" options, such as having a repository on an internal server somewhere for use by development team within an organization.

The `build.gradle` file for the `plugin/` module sets up tasks, via the `maven` plugin, to deploy the plugin JAR as an artifact to a repository located in a `repository/` directory off of the project root. This would be reasonable for a plugin that is being used by other modules in that project but not other projects, as is the case here.

```
apply plugin: 'groovy'
apply plugin: 'java'

dependencies {
    implementation gradleApi()
    implementation localGroovy()
}

sourceCompatibility = "1.7"
targetCompatibility = "1.7"

group 'com.commonsware.android.gradle'
version '0.0.1'

apply plugin: 'maven'
```

```
uploadArchives {
    repositories {
        mavenDeployer {
            repository(url: uri('../repository'))
        }
    }
}
```

(from Gradle/PluginStub/plugin/build.gradle)

The `group` provides the artifact group ID for this plugin — the name that appears left-most in the `group-id:artifact-id:version` triple that we use when referencing these sorts of dependencies. The artifact ID is the name of the module itself by default.

The `uploadArchives` configuration teaches the `maven` plugin where we want to push the artifact to. In this case, it is to a `../repository/` directory relative to the module root, which places the `repository/` directory off of the project root.

You can run the `uploadArchives` task, directly from Gradle if you wish, by opening the Gradle tool (typically docked on the right) and finding the `uploadArchives` task within an `upload` task group in the `:plugin` module:

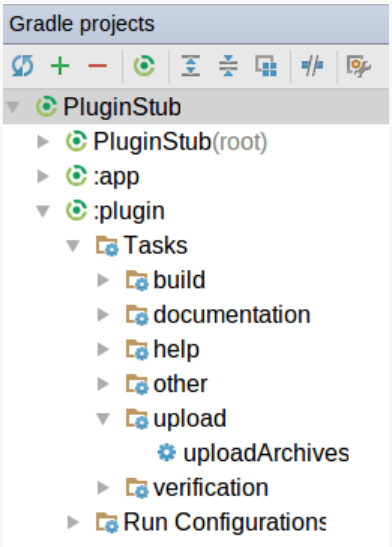

Figure 344: Gradle Task Tree, Showing uploadArchives Task

Once you run that task, you will find a `repository/` directory off of the project root, with our JAR file as an artifact:

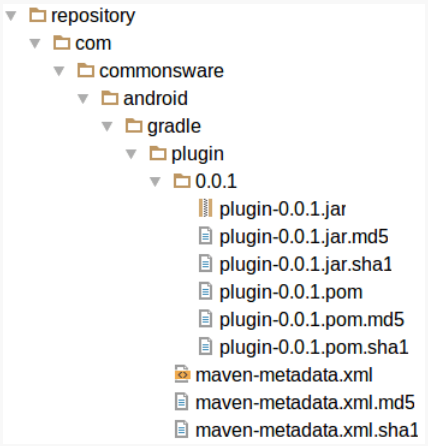

Figure 345: Gradle Task Tree, Showing Local Repository

Using the Plugin

Now, other modules in this project can use the plugin, such as the `app/` module, containing an Android app created through the Android Studio new-project wizard, without any changes to the generated Java code, resources, or manifest.

In a typical Android Studio project, you see plugins added via the `buildscript` closure in the `build.gradle` file in the project's root directory. Technically, this is only required for plugins that either all modules will use, or enough modules will use that it makes sense to define it in one place.

A module's own `build.gradle` file can also load third-party plugins, using the same `buildscript` closure. This will be added to the plugins loaded from the project's `build.gradle` file to create the complete list of possible plugins for the module.

So, the `app/` module takes this approach in its `build.gradle` file:

```
buildscript {
    repositories {
        maven {
            url uri('../repository')
        }
    }
    dependencies {
        classpath 'com.commonsware.android.gradle:plugin:0.0.1'
    }
}
```

```
apply plugin: 'com.android.application'
apply plugin: 'com.commonsware.android.gradle.plugin'
```

(from Gradle/PluginStub/app/build.gradle)

Here, we indicate that the plugin search path should include our custom `repository/`, and that we are looking for a plugin artifact identified as `com.commonsware.android.gradle:plugin:0.0.1`. That lines up with the group ID, artifact ID, and version number that our plugin used, and this JAR can be found in our local repository, assuming that we have run the `uploadArchives` tasks from the `plugin/` module.

We also use `apply plugin: 'com.commonsware.android.gradle.plugin'` to actually use the plugin. Here, the name of the plugin comes from the name of the `.properties` file that we put in the `resources/META-INF/gradle-plugins/` directory of the `plugin/` module.

The rest of the `app/` module's `build.gradle` file (not shown) is the standard stuff that you get in a `build.gradle` file for an application module out of the new-project wizard.

With that in place, we now have a new `stubTask` task, inside of a `commonsware` group (per our plugin's task configuration in the Groovy code) that we can run:

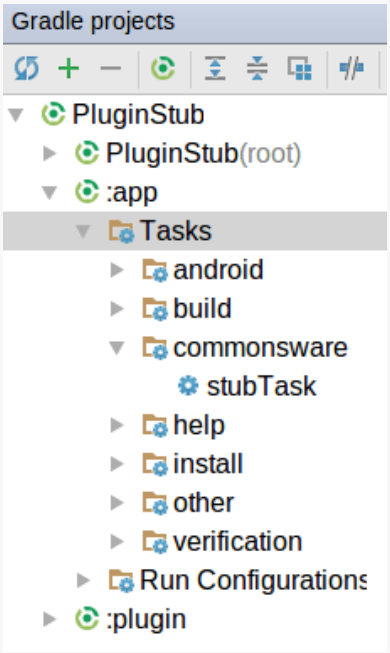

Figure 346: Gradle Task Tree, Showing stubTask Task

If you run that task — and if Android Studio is behaving today – you will see our static message show up in the Gradle Console output:

```
Executing tasks: [stubTask]

Configuration on demand is an incubating feature.
Observed package id 'system-images;android-14;default;armeabi-v7a' in inconsistent
location '/opt/android-sdk-linux/system-images/android-14/armeabi-v7a' (Expected
'/opt/android-sdk-linux/system-images/android-14/default/armeabi-v7a')
Observed package id 'system-images;android-14;default;armeabi-v7a' in inconsistent
location '/opt/android-sdk-linux/system-images/android-14/armeabi-v7a' (Expected
'/opt/android-sdk-linux/system-images/android-14/default/armeabi-v7a')
Incremental java compilation is an incubating feature.
:app:stubTask
Hello, world!

BUILD SUCCESSFUL

Total time: 13.707 secs
```

Dealing with Bugs and Changes

If you develop your own Gradle plugin, you may find the development process to be a bit of a pain. This is particularly true in cases like the sample project, where the plugin and a module using the plugin exist in the same project.

For example, what happens when you run `uploadArchives` and the plugin has a bug?

In this particular case, usually there is not much of a problem, insofar as nothing depends upon `stubTask`. However, if your bug affects the plugin as a whole — for example, you screw up the `.properties` file – now your entire build process is broken, *even for the plugin module*. In the case of a plugin configuration bug, you cannot successfully sync your project with the Gradle build files.

When you get into more sophisticated plugins, where you chain new tasks onto the existing build process (e.g., for code generation), you will run into cases where bugs in the plugin allow you to still sync your project with the Gradle build files, but attempts to build anything trip over the plugin bug. This can even affect builds of the *plugin*, depending on the nature of the plugin bugs.

As a result, you will find yourself commenting out the use of the plugin in the other module(s) from time to time, cleaning the project, fixing the plugin bug, running `uploadArchives` with the repaired plugin, then uncommenting those commented-out lines, and trying it again. Depending on how good you are with bug-fixing, this may take some time.

Also, even though the plugin is being used by one module and the implementation is in a separate module, Android Studio may erroneously flag your Groovy-defined classes as having errors, indicating that these classes already exist. Just clean the project, and those spurious errors should go away.

Trying the Sample App

The sample app is set up to apply the custom plugin. Unfortunately, when you first check out this project, that custom plugin does not yet exist. And, due to the way Android Studio and Gradle work, you cannot build the plugin, because the `app/` module fails the build due to the missing plugin... even if you are not trying to build the `app/` module.

So, to try out this sample app, you will need to:

- Comment out the `buildscript` closure and the `apply plugin:` statement in `app/build.gradle` that refer to our custom plugin
- Import the project into Android Studio
- Run the `uploadArchives` tasks in the `plugin/` module, to build and "upload" the plugin to our local repository
- Uncomment what you commented in the first bullet above

Then, everything should be set.

Creating a Real Plugin

The stub plugin shown in this chapter is extremely rudimentary. It is enough to demonstrate the scaffolding necessary to create a plugin, and little else.

The `Staticizer` plugin demonstrated in the next chapter is a more sophisticated sample, generating Java code to be blended into a project build, just like the data binding framework, SQLDelight, and other Gradle plugins do.

But, `Staticizer` needs a few more features in its plugin than `PluginStub` needed.

Integrating with the Android Plugin

If you want to add tasks that tie into the build process of an Android app or library, you will wind up needing to reference portions of the public API exposed by the Android Gradle Plugin. That, in turn, will require you to have the plugin depend upon the Android Plugin for Gradle, so you can reference the appropriate symbols:

So, you might have a `dependencies` closure in the plugin's `build.gradle` file like this:

```
dependencies {
    compile gradleApi()
    compile localGroovy()
    implementation 'com.android.tools.build:gradle:2.2.2'
}
```

Here, we are saying that we are dependent upon the Android Plugin for Gradle (specifically version 2.2.2).

You can use similar `implementation` statements to pull in other libraries that your plugin might need, such as Gson.

Validating the Environment

If you are planning on integrating into the Android build process, you may want to validate that your plugin is being used in a module that has *also* applied the `com.android.application` or `com.android.library` plugin. Otherwise, your plugin would have nothing to do.

Chiu-ki Chan demonstrated an approach for doing this in her `gce2retrofit` Gradle plugin example. In her case, her plugin can work with either of the two Android plugins or the plain `java` plugin. She takes advantage of the fact that a `Project` knows its `plugins`, and we can use `hasPlugin` to see if the `Project` is configured with certain plugins or not:

```
package com.sqisland.gce2retrofit;

import com.android.build.gradle.AppPlugin;
import com.android.build.gradle.LibraryPlugin;

import org.gradle.api.Project;
import org.gradle.api.Plugin;
import org.gradle.api.plugins.JavaPlugin;

public class GradlePlugin implements Plugin<Project> {
  @Override
  public void apply(Project project) {
    def hasAndroidApp = project.plugins.hasPlugin AppPlugin
    def hasAndroidLib = project.plugins.hasPlugin LibraryPlugin
    def hasJava = project.plugins.hasPlugin JavaPlugin
    if (!hasAndroidApp && !hasAndroidLib && !hasJava) {
      throw new IllegalStateException("'android' or 'android-library' or 'java'
plugin required.")
    }

    // more code here
```

(from her plugin's `GradlePlugin.groovy` script)

Here, she checks for all three possible plugins and throws an exception if they are all missing.

Writing a Task Class

In the `PluginStub` sample, our task was implemented as the Groovy equivalent of a Java anonymous inner class. For trivial tasks, that is a reasonable approach. The

bigger your task, the more likely it is that you will want to create a formal dedicated class for the task.

In that case, rather than using syntax like this to add a task:

```
def myTask = target.tasks.create("stubTask") << {
  def helper = new StubHelper();
  println helper.getMessage();
}

myTask.group = "commonsware"
```

you use syntax like this:

```
def myTask = project.tasks.create("commonsware", SomeTask)
```

Here, `SomeTask` is a dedicated class, extending Gradle's `DefaultTask` base class. That class can be written in Java or Groovy, much as the plugin class itself can be written in Java or Groovy.

Splicing Your Task Into the Build

In the `PluginStub` sample, `stubTask` is a standalone task. Running other tasks, such as building an app, would never invoke `stubTask`. Occasionally, this is what you want. Other times, you want your custom task to be invoked as part of the overall build process. For example, with code generation, you want to get a chance to generate Java code at the same points in time when other Java code gets generated (e.g., `R` class), before the Java code gets compiled.

That gets to be a bit complicated. While Gradle has a fairly simple approach for declaring that one task depends upon another, in an Android build, we have many build variants to deal with, based on build type and, possibly, product flavor.

The recipe is to create a custom task for *each* build variant:

```
variants.all { variant ->
  def task=
      target.tasks.create("doSomething${variant.name.capitalize()}",
          DoSomethingTask)
  variant.javaCompile.dependsOn task
}
```

Here, we create a custom task, for a `Project` named `target`. The task is named `doSomething...`, where the `...` is replaced by the name of the build variant with the first letter capitalized. So, we wind up with custom tasks like `doSomethingDebug` or `doSomethingAmazonRelease` or whatever.

We also indicate that the existing task that performs the Java compilation (`variant.javaCompile`) depends upon our new task. Hence, our task will be executed before the Java code gets compiled.

And, we do this in a loop over all possible build variants (`variants.all`) for whatever module our code is in. The catch is that getting that list of variants varies, depending upon whether we are building an Android application or an Android library:

```
def isApp=target.plugins.hasPlugin AppPlugin
def isLib=target.plugins.hasPlugin LibraryPlugin

if (!isApp && !isLib) {
  throw new
    IllegalStateException("This plugin depends upon the com.android.application or
com.android.library plugins")
}

def variants

if (isApp) {
  variants=target.android.applicationVariants
}
else {
  variants=target.android.libraryVariants
}
```

We set `variants` to be the `applicationVariants` or the `libraryVariants` depending upon whether we are in an Android app module or an Android library module.

Configuring the Plugin

When we write our Android apps and libraries, we almost always have an `android` closure that we use to configure the behavior of the Android build process and results (e.g., `minSdkVersion`).

This is what Gradle refers to as an “extension object”, and your plugin can register one of these.

Simply create a Java or Groovy class that defines what properties you want to be configurable:

```
class StaticizerConfig {
  def String packageName
}
```

Then, create a new extension object, by calling `create()` on the `extensions` collection inside of the `Project` (here named `target`):

```
target.extensions.create('staticizer', StaticizerConfig)
```

This will allow users of this plugin to create a `staticizer` and supply a value for a `packageName` property:

```
apply plugin: 'com.commonsware.android.staticizer'

staticizer {
    packageName 'com.commonsware.android.staticizer.demo'
}
```

We will see more about this `staticizer` extension object in the next chapter.

Code Generation

One common thing to do in a Gradle plugin is to generate Java code. Code that writes other code based upon supplied inputs is referred to as a "code generator".

At its core, Java code is just text. Developers generate text on the fly quite a bit, particularly in Web development. There are two main approaches to such text generation:

1. Use templates, when the text is largely fixed but has some values that need to be replaced at runtime
2. Use regular code to generate the text, perhaps using APIs that facilitate writing out text formats with as little coding overhead as possible

In this chapter, we will examine what it takes to generate Java code from a Gradle plugin. In particular, we will look at the second approach, where we will have Java code that generates other Java code, using a library that makes this a lot easier than writing a lot of `append()` calls to a `StringBuilder`.

Prerequisites

Understanding this chapter requires that you have read the preceding chapter and all of its prerequisites.

What Drives the Custom Code?

You could generate code based off of random numbers. More likely, there is some sort of input that you are using to determine the code to be generated. This input

can be divided roughly into three areas: other Java code, other project files, and everything else.

Other Java Code

Modern Android code gets littered with annotations. Some are from standard Java (e.g., `@Override`). Some are from Android libraries (e.g., `@NotNull`). Some are from third-party libraries, like greenrobot's EventBus (e.g., `@Subscribe`).

Sometimes, these annotations are for validation at compile time. `@Override` tells Java compilers that we think that we are overriding a method from a superclass or are implementing an interface method, and so the compile should fail if our method signature does not match anything that we could be overriding. `@NotNull` indicates that a parameter should not be `null`, allowing static code analysis to help point out places where we might accidentally pass `null` in as a value.

Sometimes, these annotations are used by third-party libraries at runtime. greenrobot's EventBus, for example, will look for `@Subscribe` annotations to determine how to deliver events to registered event-handling objects.

Sometimes, these runtime annotations generate something resembling code at runtime. Retrofit, for example, creates an instance of our service interface at runtime, with an implementation that will make the Web service requests that we desire. However, this Java bytecode is generated on devices, not as ordinary Java source files that are included in the build.

But, sometimes, these annotations get used by compile-time annotation processors. These add-ons to the build process read in Java code, analyze it (annotations in particular), and code generate Java code in support of our existing Java code. Google's AutoValue processor, for example, looks for `@AutoValue`-annotated `abstract` classes and code-generates a concrete implementation of a "value class" (one with immutable members), complete with `hashCode()`, `equals()`, and related methods.

Other Project Files

A code generator might generate Java code from other types of input that are in the project:

- The data binding framework looks for layout resources with a specific structure (root `<layout>` element) and code-generates Java binding classes for them
- SQLDelight code-generates a `SQLiteOpenHelper` subclass based upon a SQL script that you include in your module

Here, the inputs are resources or other files, not annotated Java code.

Other Data Sources

There is nothing stopping you from generating code based on inputs that come from outside of the project. For example, whereas SQLDelight works off of SQL scripts in your project tree, you can imagine a similar code generator that retrieved schemas from a live database using database I/O.

The big advantage of limiting code generation to files in the project is having reproducible builds based on version control. Ideally, years from now, you should be able to check out a branch or tag from a version control system and be able to build the project the same way then as you do on the day you committed that code to version control. That works best when the entire project specification is included in version control. A server is not, and the server response in a few years might differ from what the server response is today.

One workaround for this is to have two tools. One retrieves the data from the server and writes that data out into files that go into your project (e.g., JSON files). You would run this code from time to time, when you specifically need to get the latest configuration from the server. However, the second tool performs the code generation, working off of the project files, not from the live server data. That way, you can perform that code generation again in the future in a reproducible fashion.

Java as Poetry

In principle, all you need is `StringBuilder` to build up a Java source file to eventually write to disk. Similarly, in principle, all you need is `StringBuilder` to construct a Web page for your Web app to serve to the browser. In both cases, there are better solutions that can simplify the work and make it less prone to bugs.

In the case of Java code generation, the leading solution is JavaPoet, yet another library from Square. JavaPoet offers a fluent, builder-style API for defining the pieces

of a Java source file, such as fields and methods wrapped in classes. Then, JavaPoet can write out a formatted Java source file based upon your supplied specification.

JavaPoet is based on Square's earlier JavaWriter library, which has been discontinued.

The code-generating sample app described in this chapter takes advantage of JavaPoet for generating its Java code.

Writing a Code Generation Plugin

Sometimes, your app has some pure data that it needs. For example, the APK edition of this book needs to know what chapters there are, where the chapter HTML files are, what the chapter titles are, and so forth.

A typical approach for handling this is to have some data file that you package in your app. Perhaps it is an XML resource (`res/xml/`), a raw resource (`res/raw/`), or an asset (`assets/`). You then have code that reads in the data at runtime and uses it.

This has a couple of downsides:

- Your code gets littered with checked exceptions, for I/O errors or parsing errors that, in principle, should never occur with pre-packaged validated data files
- This sort of disk I/O should be done on a background thread, making it more painful to get this data into your app

The `Gradle/Staticizer` sample project implements a Gradle plugin that takes some static JSON and code generates a Java class exposing that data. Rather than having to read in and parse the JSON at runtime, you just refer to the generated Java class. This eliminates the extraneous exceptions and reduces the effective cost for loading the data off of disk (as we do not worry about somehow loading Java code in the background).

This particular sample is not very sophisticated. It is limited to JSON files describing objects made up of primitives (numbers and strings), such as:

```
{
  "foo": "foobar",
  "versionCode": 1
}
```

(from Gradle/Staticizer/app/src/main/staticizer/TestData.json)

A production-grade implementation would handle nested Java objects, arrays, and the like. But, this demonstrates the basic concept of code generation, in a not-unrealistic scenario, just with a limited implementation to keep the sample simple.

Designing the Output

We want a Java class that offers up the same data that is in the JSON, just without the runtime JSON loading and parsing. For example, the `TestData.json` file shown above, represented in Java, might look like:

```
package com.commonsware.android.staticizer.demo;

import java.lang.String;

public final class TestData {
  public static final String FOO = "foobar";

  public static final double VERSION_CODE = 1.0;
}
```

(from Gradle/Staticizer/app/build/generated/source/staticizer/debug/com/commonsware/android/staticizer/demo/TestData.java)

Early on, you might hand-craft such a Java class, to test out how it works and ensure that you have the right fields, data types, and so on for your needs. Then, once you have the class designed the way you want, you can determine how to map the data from your input into the desired output.

In the case of this sample app, we take a fairly literal approach to converting the JSON to Java:

- The class name is based on the JSON file name (`TestData.json` turns into `TestData.java`)
- The package should be configurable, as part of setting up the plugin
- The field names are based on the object keys from the JSON, but converted into `ALL_CAPS_WITH_UNDERSCORES` (a typical Java convention for `static` field names) instead of `camelCase` (a typical JSON convention for object attribute names)
- The fields are `public static final`, akin to the fields on the code-generated `R` class that you get from the Android build tools

- The data types should roughly match the JSON input, so if the JSON has a number, we emit an appropriate numeric data type (e.g., `double`), otherwise we emit a `String`

Crafting the Plugin

The plugin itself is based upon the `PluginStub` sample project from the preceding chapter. In this case, the plugin is in the `staticizer/` module, which once again is a plain Java module, not an Android application or library module.

The `build.gradle` file for the `staticizer/` module is similar to the one from the `PluginStub` sample:

```
apply plugin: 'groovy'
apply plugin: 'java'

dependencies {
    compile gradleApi()
    compile localGroovy()
    compile 'com.android.tools.build:gradle:2.2.2'
    compile 'com.squareup:javapoet:1.7.0'
    compile 'com.google.code.gson:gson:2.7'
    compile 'com.google.guava:guava:19.0'
}

sourceCompatibility = "1.7"
targetCompatibility = "1.7"

group 'com.commonsware.android'
version '0.0.1'

apply plugin: 'maven'

uploadArchives {
    repositories {
        mavenDeployer {
            repository(url: uri('../repository'))
        }
    }
}
```

(from Gradle/Staticizer/staticizer/build.gradle)

It has four new dependencies:

- the Android Gradle Plugin, as we will be hooking into Android-specific build tasks
- JavaPoet, for our Java code generation
- Gson, for parsing the JSON
- Google's Guava library, for some utility classes, specifically for handling the case conversion of our field names

(Guava has a bit of a bad reputation in Android circles owing to the large size of the library, but bear in mind that this is a Java module creating a Gradle plugin, so the Guava code is not running on an Android device)

We have a `com.commonsware.android.staticizer.properties` file in `main/resources/META-INF/gradle-plugins/`, pointing to a `com.commonsware.android.staticizer.StaticizerPlugin` class:

```
implementation-class=com.commonsware.android.staticizer.StaticizerPlugin
```

(from Gradle/Staticizer/staticizer/src/main/resources/META-INF/gradle-plugins/com.commonsware.android.staticizer.properties)

The `StaticizerPlugin` class is implemented in Groovy:

```
package com.commonsware.android.staticizer

import org.gradle.api.Plugin
import org.gradle.api.Project
import com.android.build.gradle.AppPlugin
import com.android.build.gradle.LibraryPlugin

public class StaticizerPlugin implements Plugin<Project> {
  @Override
  public void apply(Project target) {
    def isApp=target.plugins.hasPlugin AppPlugin
    def isLib=target.plugins.hasPlugin LibraryPlugin

    if (!isApp && !isLib) {
      throw new
        IllegalStateException("This plugin depends upon the com.android.application or com.android.library
plugins")
    }

    target.extensions.create('staticizer', StaticizerConfig)

    def variants

    if (isApp) {
      variants=target.android.applicationVariants
    }
    else {
      variants=target.android.libraryVariants
    }
```

```
    variants.all { variant ->
      def task=
          target.tasks.create("staticize${variant.name.capitalize()}",
              StaticizerTask)

      task.outputDir=
          new File("${target.buildDir}/generated/source/staticizer/${variant.name}")
      task.group="commonsware"
      task.description="Generate ${variant.name} Java code from JSON"

      variant.javaCompile.dependsOn task
      variant.registerJavaGeneratingTask task, task.outputDir
    }
  }
}

class StaticizerConfig {
  def String packageName
}
```

(from Gradle/Staticizer/staticizer/src/main/groovy/com/commonsware/android/staticizer/StaticizerPlugin.groovy)

Here, we:

- Validate that the module also has the `com.android.application` or `com.android.library` plugins
- Create a `staticizer` extension object, using the `StaticizerConfig` class, to allow a module using this plugin to give us a `packageName` to use for generating the Java class files
- Get the build variants for the library or application
- Iterate over those variants and create a custom task for each, using a `StaticizerTask` class that we will see shortly

Each task is given a name based on the build variant name (e.g., `staticizerDebug`), courtesy of Groovy's string interpolation (`${}` syntax), the `name` property of the build variant, and the `capitalize()` method to capitalize the first letter.

We need to tell the task where it should write the Java code to. If you look in `build/generated/source/` for a typical Android module, you will see a bunch of directories of generated source files. The top directory will be an indication of what the source pertains to (e.g., `r` for the `R` class, `buildConfig` for the `BuildConfig` class). In there, you will see subdirectories by build variant (e.g., `buildConfig/debug/`), and in there will be a typical Java package directory tree leading to source code. So, we follow the same basic pattern:

- Get the `build/` directory via `target.buildDir`
- Append `generated/source/` to get to the standard location for generated source code

- Append `staticizer/` to give us a hopefully-unique directory of source
- Append the variant name so that each variant's edition of this task has its own output directory

We also:

- Associate the task with a `commonsware` group
- Give the task a description, blending in the build variant name for fun
- Say that the standard Java compilation task depends upon this new task, so our task will run before the Java code gets compiled
- Indicate that our task is generating Java source code (`registerJavaGeneratingTask`)

Writing the Task

`StaticizerTask` is a separate Groovy-defined class, extending `DefaultTask`, that serves as the task implementation:

```
package com.commonsware.android.staticizer

import org.gradle.api.DefaultTask
import org.gradle.api.tasks.InputDirectory
import org.gradle.api.tasks.OutputDirectory
import org.gradle.api.tasks.TaskAction
import org.gradle.api.tasks.incremental.IncrementalTaskInputs

public class StaticizerTask extends DefaultTask {
  @InputDirectory
  File inputDir=new File(project.getProjectDir(), "src/main/staticizer")

  @OutputDirectory
  File outputDir

  @TaskAction
  public void execute(IncrementalTaskInputs inputs) {
    if (!project.staticizer.packageName) {
      throw new IllegalStateException('staticizer.packageName is undefined!')
    }

    def staticizer=new Staticizer();

    for (File input : inputDir.listFiles()) {
      if (!input.name.startsWith(".")) {
        staticizer.generate(input, outputDir,
            project.staticizer.packageName);
```

```
      }
    }
  }
}
```

(from Gradle/Staticizer/staticizer/src/main/groovy/com/commonsware/android/staticizer/StaticizerTask.groovy)

This class has two fields. One, `outputDir`, is populated by `StaticizerPlugin` based on our build variant. The other, `inputDir`, is populated by:

- Getting the module's root directory via `getProjectDir()` on the `project` (where `project` is an inherited field pointing to the `Project`)
- Appending `src/main/staticizer` as being the directory where we expect to find the JSON files to convert into Java code

This does not take into account build variants, so we cannot have separate JSON in a `debug/` source set, for example. A fully production-grade version of this plugin would handle that.

The `@InputDirectory` and `@OutputDirectory` annotations tell Gradle the roles of these directories. In particular, Gradle uses this to determine whether our outputs are up to date with respect to our inputs, and therefore whether this task is needed or can be skipped.

The `execute()` method is annotated with `@TaskAction` and represents the entry point into the task. There, we:

- Confirm that we have a `packageName` in the `staticizer` extension object, though production-grade code would validate that this is a valid Java package name
- Create a Java `Staticizer` object that will do the actual code generation
- Iterate over all files in the `inputDir`, throw out those beginning with `.` (to filter out `.` and `..`, along with any leading-dot "hidden files"), and call `generate()` on the `Staticizer` for each

Production-grade code would confirm that the files are files and do something useful with subdirectories (e.g., recurse into them).

Between the `StaticizerPlugin` and `StaticizerTask`, we have implemented the Gradle plugin code. `Staticizer` itself knows nothing about Gradle. Its `generate()` method just knows that it is to take an input file, generate a Java output file, and use

a certain Java package while doing so. Hence, `Staticizer` could be used in other ways (e.g., command-line interface), tested separately, etc.

Generating Java Code

After all of that setup, the actual work of generating Java code is almost anti-climactic. Partly, that is due to the power of JavaPoet. Partly, that is due to the limited nature of the sample.

`Staticizer` is a plain Java class. Its `execute()` method is responsible for parsing the JSON and writing the corresponding Java code out to the designated location:

```
void generate(File input, File outputDir,
              String packageName) throws IOException {
  Type type=
    new TypeToken<LinkedHashMap<String,Object>>() {}.getType();
  LinkedHashMap<String, Object> data=
    new Gson().fromJson(new FileReader(input), type);
  String basename=removeExtension(input.getAbsolutePath());
  TypeSpec.Builder builder=TypeSpec.classBuilder(basename)
    .addModifiers(Modifier.PUBLIC, Modifier.FINAL);

  for (Map.Entry<String, Object> entry : data.entrySet()) {
    String fieldName=
      CaseFormat.LOWER_CAMEL
        .to(CaseFormat.UPPER_UNDERSCORE, entry.getKey());
    FieldSpec.Builder field;

    if (entry.getValue() instanceof Float) {
      field=FieldSpec.builder(TypeName.FLOAT, fieldName)
        .initializer("$L", entry.getValue());
    }
    else if (entry.getValue() instanceof Double) {
      field=FieldSpec.builder(TypeName.DOUBLE, fieldName)
        .initializer("$L", entry.getValue());
    }
    else if (entry.getValue() instanceof Integer) {
      field=FieldSpec.builder(TypeName.INT, fieldName)
        .initializer("$L", entry.getValue());
    }
    else if (entry.getValue() instanceof Long) {
      field=FieldSpec.builder(TypeName.LONG, fieldName)
        .initializer("$L", entry.getValue());
    }
    else if (entry.getValue() instanceof Boolean) {
      field=FieldSpec.builder(TypeName.BOOLEAN, fieldName)
```

```
        .initializer("$L", entry.getValue());
    }
    else {
      field=FieldSpec.builder(String.class, fieldName)
        .initializer("$S", entry.getValue().toString());
    }

    field.addModifiers(Modifier.PUBLIC, Modifier.STATIC, Modifier.FINAL)
      .build();

    builder.addField(field.build());
  }

  JavaFile.builder(packageName, builder.build())
    .build()
    .writeTo(outputDir);
}
```

(from Gradle/Staticizer/staticizer/src/main/java/com/commonsware/android/staticizer/Staticizer.java)

Let's take this a piece at a time.

We have no idea what the JSON will look like, other than it should be a JSON object (versus being an array). The first few lines go through a typical Gson recipe to convert the JSON into a `Map` representing that object:

```
  Type type=
    new TypeToken<LinkedHashMap<String,Object>>() {}.getType();
  LinkedHashMap<String, Object> data=
    new Gson().fromJson(new FileReader(input), type);
```

(from Gradle/Staticizer/staticizer/src/main/java/com/commonsware/android/staticizer/Staticizer.java)

The Java class name should match the JSON file name, just without the extension. The `removeExtension()` method is a simple algorithm for giving us the base name of the JSON file:

```
// inspired by http://stackoverflow.com/a/990492/115145

private static String removeExtension(String s) {
  String result;

  int sepIndex=
    s.lastIndexOf(System.getProperty("file.separator"));

  if (sepIndex==-1) {
    result=s;
```

```
    }
    else {
      result=s.substring(sepIndex+1);
    }

    int extIndex=result.lastIndexOf(".");

    if (extIndex!=-1) {
      result=result.substring(0, extIndex);
    }

    return(result);
  }
```

(from Gradle/Staticizer/staticizer/src/main/java/com/commonsware/android/staticizer/Staticizer.java)

We are looking to create a Java class. For that, JavaPoet offers `TypeSpec.classBuilder()`, which gives us a `TypeSpec.Builder` set up to build a class with the supplied name. We call `addModifiers()` to indicate that the class should be `public` and `final` (meaning that the class cannot be subclassed):

```
    TypeSpec.Builder builder=TypeSpec.classBuilder(basename)
      .addModifiers(Modifier.PUBLIC, Modifier.FINAL);
```

(from Gradle/Staticizer/staticizer/src/main/java/com/commonsware/android/staticizer/Staticizer.java)

We then iterate over all the entries in the `Map` loaded by Gson. For each, we want to define a field in our Java class. For that, we will need the field name, which should be the name of the attribute in the JSON object, but with the `camelCase` name replaced by `ITS_ALL_CAPS_EQUIVALENT`. Guava has a `CaseFormat` class that encapsulates this sort of conversion, so we indicate that we want to convert from "lower camel" formatting to "upper underscore" formatting:

```
      String fieldName=
        CaseFormat.LOWER_CAMEL
          .to(CaseFormat.UPPER_UNDERSCORE, entry.getKey());
```

(from Gradle/Staticizer/staticizer/src/main/java/com/commonsware/android/staticizer/Staticizer.java)

We then need to set up a `FieldSpec.Builder` for the field that we want to add. Just as JavaPoet's `TypeSpec` generates a Java type (class, interface, etc.), `FieldSpec` generates a field within a type.

However, one of the parameters of the `FieldSpec.builder()` method is the data type of the resulting field. Gson has its own algorithm for determining what data

type to use for the values it parses. So, we use `instanceof` to determine the type of the attribute value, and we use that to determine how to set up the `FieldSpec.Builder`. For example, we use this code if the value is a `Double`:

```
      else if (entry.getValue() instanceof Double) {
        field=FieldSpec.builder(TypeName.DOUBLE, fieldName)
          .initializer("$L", entry.getValue());
      }
```

(from Gradle/Staticizer/staticizer/src/main/java/com/commonsware/android/staticizer/Staticizer.java)

We tell `FieldSpec.builder()` to give us a `FieldSpec.Builder` set up to define a `double` field whose name is the `fieldName` that we got from the `CaseFormat` conversion of the attribute name. We specifically want that field to be initialized with the value itself, and for numeric or `boolean` fields, the JavaPoet syntax for that is to pass `$L` to `initializer()`, along with the value to be initialized.

If the value we got from Gson does not appear to be a number or a `boolean`, we treat it as a `String`:

```
      else {
        field=FieldSpec.builder(String.class, fieldName)
          .initializer("$S", entry.getValue().toString());
      }
```

(from Gradle/Staticizer/staticizer/src/main/java/com/commonsware/android/staticizer/Staticizer.java)

Here, `$S` teaches JavaPoet to examine the `String` that we supply and add in any escape sequences that might be needed (e.g., for embedded quotation marks).

No matter what the type of the field is, we indicate that it should be `public static final` via an `addModifiers()` call, before adding the field to the class:

```
      field.addModifiers(Modifier.PUBLIC, Modifier.STATIC, Modifier.FINAL)
        .build();

      builder.addField(field.build());
```

(from Gradle/Staticizer/staticizer/src/main/java/com/commonsware/android/staticizer/Staticizer.java)

After processing the entire JSON object, we create a `JavaFile.Builder`, teaching it the Java package name plus the type that goes into the file, and we write the resulting `JavaFile` out to `outputDir`:

```
    JavaFile.builder(packageName, builder.build())
      .build()
      .writeTo(outputDir);
```

(from Gradle/Staticizer/staticizer/src/main/java/com/commonsware/android/staticizer/Staticizer.java)

`JavaFile` will handle all the details of creating the appropriate set of subdirectories underneath `outputDir` based upon the Java package name.

Note that while developing this sort of logic, if you change your code-generation algorithm, you will need to clean your project as part of trying out the revised code. Gradle compares input and output to see if changes are needed, but it does not take the age of the plugin into account, and so it will not realize that your output would differ not because of changes to the input, but due to changes in the algorithm used to generate the output.

Using the Generated Code

The `app/` module in this project then uses the plugin, assuming that we have run `uploadArchives` in the plugin's module to publish the plugin to the local repository:

```
buildscript {
    repositories {
        jcenter()
        maven {
            url uri('../repository')
        }
    }
    dependencies {
        classpath 'com.commonsware.android:staticizer:0.0.1'
    }
}

apply plugin: 'com.android.application'
apply plugin: 'com.commonsware.android.staticizer'

staticizer {
    packageName 'com.commonsware.android.staticizer.demo'
}

android {
    compileSdkVersion 25
    buildToolsVersion '26.0.2'
    defaultConfig {
        minSdkVersion 15
```

```
        targetSdkVersion 25
        versionCode 1
        versionName "1.0"
    }
}
```

(from Gradle/Staticizer/app/build.gradle)

We configure `packageName` on `staticizer` to be the same Java package that our activity source code happens to reside in, though that is not required.

We need to add the `staticizer/` directory to the `main/` source set and add in whatever JSON files we want, with appropriate filenames for the Java classes that we want to generate.

Then, our application code can refer to our custom-generated Java class (`TestData` in this case), the same way that it can refer to `R`, `BuildConfig`, or other Java classes generated by the standard Android build tools:

```
package com.commonsware.android.staticizer.demo;

import android.app.Activity;
import android.os.Bundle;
import android.widget.TextView;

public class MainActivity extends Activity {
  @Override
  protected void onCreate(Bundle savedInstanceState) {
    super.onCreate(savedInstanceState);
    setContentView(R.layout.activity_main);

    TextView tv=(TextView)findViewById(R.id.some_string);

    tv.setText(TestData.FOO);
    tv=(TextView)findViewById(R.id.version_code);
    tv.setText(Double.toString(TestData.VERSION_CODE));
  }
}
```

(from Gradle/Staticizer/app/src/main/java/com/commonsware/android/staticizer/demo/MainActivity.java)

Advanced Gradle for Android Tips

There are *lots* of things you can do given a full scripting language as the basis for your build system. This chapter represents a collection of tips for things that you can do that go beyond stock capabilities provided by the Android Gradle Plugin.

Prerequisites

Understanding this chapter requires that you have read the chapters that introduce Gradle and cover basic Gradle/Android integration, including the project structure.

Gradle, DRY

Ideally, your build scripts do not repeat themselves any more than is logically necessary. For example, a project and sub-projects probably should use the same version of the build tools, yet by default, we define them in each `build.gradle` file. This section outlines some ways to consolidate this sort of configuration.

It's build.gradle All The Way Down

If you have sub-projects, you can have `build.gradle` files at each level of your project hierarchy. Your top-level `build.gradle` file is also applied to the sub-projects when they are built.

In particular, you can "pass data" from the top-level `build.gradle` file to sub-projects by configuring the `ext` object via a closure. In the top-level `build.gradle` file, you would put common values to be used:

```
ext {
   compileSdkVersion=26
}
```

(note the use of the = sign here)

Sub-projects can then reference `rootProject.ext` to retrieve those values:

```
android {
    compileSdkVersion rootProject.ext.compileSdkVersion
}
```

By this means, you can ensure that whatever needs to be synchronized at build time is synchronized, by defining it once.

Another way that a top-level `build.gradle` file can configure subprojects is via the `subprojects` closure. This contains bits of configuration that will be applied to each of the subprojects as a part of their builds.

Note that `subprojects` applies to *all* sub-projects (a.k.a., modules), which limits its utility. For example, a top-level project with one sub-project for an app and another sub-project for a library used by that app cannot readily use `subprojects`. That is because the library sub-project needs to configure the `com.android.library` plugin, while the application sub-project needs to configure the `com.android.application` plugin. The `subprojects` closure is only good for common configuration to apply to all sub-projects regardless of project type.

gradle.properties

Another approach would be to add a `gradle.properties` file to your project root directory. Those properties are automatically read in and would be available up and down your project hierarchy.

Per-developer properties can go in a `gradle.properties` file in the user's Gradle home directory (e.g., `~/.gradle` on Linux), where they will not be accidentally checked into version control.

So, to achieve the synchronized `compileSdkVersion` value, you could have a `gradle.properties` file with:

```
COMPILE_SDK_VERSION=26
```

Then, your projects' `build.gradle` files could use:

```
android {
    compileSdkVersion COMPILE_SDK_VERSION
}
```

Custom Properties Files

You are also welcome to use your own custom properties files. For example, perhaps you want to use `gradle.properties` for properties that you are willing to put in version control (e.g., `BUILD_TOOLS_VERSION`), but you would *also* like to use a properties file to keep your code-signing details outside of your `build.gradle` file and out of version control.

Loading in custom properties files is slightly clunky, as it does not appear to be built into Gradle itself. However, you can take advantage of the fact that Gradle is backed by Groovy and use some ordinary Groovy code to load the properties.

```
def keystorePropertiesFile = file('keystore.properties')
def keystoreProperties = new Properties()
keystoreProperties.load(new FileInputStream(keystorePropertiesFile))
```

These three lines create a `java.util.Properties` object from a `keystore.properties` file located in the module's directory. Individual properties can be read using <> syntax, the same as Groovy uses for a `Map`:

```
signingConfigs {
  release {
    keyAlias keystoreProperties['keyAlias']
    keyPassword keystoreProperties['keyPassword']
    storeFile file(keystoreProperties['storeFile'])
    storePassword keystoreProperties['storePassword']
  }
}
```

This fills in the signing configuration from the `keystore.properties` values, assuming that the `keystore.properties` file itself has the appropriate properties:

```
storePassword=81016168
keyPassword=9f353470
keyAlias=foo
storeFile=release.jks
```

Now, your signing information is not in `build.gradle`, and you can keep a fake `keystore.properties` in version control (where the properties have invalid values), enough to allow Gradle to process the `build.gradle` file but not allow for app signing. The machine designated for doing official builds would have the real `keystore.properties` file and associated keystore.

Environment Variables

Any environment variables with a prefix of `ORG_GRADLE_PROJECT_` will show up as global variables in your Gradle script. So, for example, you can access an environment variable named `ORG_GRADLE_PROJECT_foo` by accessing a `foo` variable in `build.gradle`.

If you would prefer to use environment variables without that prefix, you can call `System.getenv()`, passing in the name of the environment variable, to retrieve its value.

Note, however, that you may or may not have access to the environment variables that you think you should. Android Studio, for example, does not expose environment variables to Gradle for its builds, and so an environment variable that you can access perfectly well from the command line may not be available in the same `build.gradle` script when run from Android Studio.

Automating APK Version Information

Once the Android Gradle Plugin started catching on, one of the first things many developers raced to do was automate the `android:versionCode` and `android:versionName` properties from the manifest. Since those can be defined in a Gradle file (overriding values from any `AndroidManifest.xml` files), and since Gradle is backed by Groovy, it is possible to programmatically assign values to those properties.

This section outlines a few approaches to that problem.

Auto-Incrementing the versionCode

Since the `android:versionCode` is a monotonically increasing integer, one approach for automating it is to simply increment it on each build. While this may seem wasteful, two billion builds is a *lot* of builds, so a solo developer is unlikely to run out. Synchronizing such `versionCode` values across a team will get a bit more

complex, but for an individual case (developer, build server, etc.), it is eminently doable using Groovy.

The Gradle/Versioning sample project uses a `version.properties` file as the backing store for the version information:

```
apply plugin: 'com.android.application'

android {
    compileSdkVersion 26
    buildToolsVersion '26.0.2'

    def versionPropsFile = file('version.properties')
    def Properties versionProps = new Properties()

    if (versionPropsFile.canRead()) {
        versionProps.load(new FileInputStream(versionPropsFile))
    }
    else {
        versionProps['VERSION_CODE']='0'
    }

    def code = versionProps['VERSION_CODE'].toInteger() + 1

    versionProps['VERSION_CODE']=code.toString()
    versionProps.store(versionPropsFile.newWriter(), null)

    defaultConfig {
        minSdkVersion 21
        targetSdkVersion 26
        versionCode code
        versionName "1.1"
    }
}
```

(from Gradle/Versioning/app/build.gradle)

First, we try to open a `version.properties` file. If we find it, we read it in. Otherwise, we initialize our `java.util.Properties` object with a `VERSION_CODE` of `0`, simulating a starting point.

The script then increments the old value by 1 to get the new code to use. The revised code is then written back to the properties file before it is applied in the `defaultConfig` closure.

The result is that our `versionCode` is automatically incremented, and you can see the value change in the `version.properties` file that is generated into the `app/` module directory:

```
#Sat Nov 04 12:44:54 EDT 2017
VERSION_CODE=3
```

(from Gradle/Versioning/app/version.properties)

Adding to BuildConfig

The Android development tools have been code-generating the `BuildConfig` class for some time now. Historically, the sole element of that class was the `DEBUG` flag, which is `true` for a debug build and `false` otherwise. This is useful for doing runtime changes based upon build type, such as only configuring `StrictMode` in debug builds.

Nowadays, the Android Gradle Plugin also defines things like:

- `BUILD_TYPE`, which is the build type used to build this APK.
- `FLAVOR`, which is the product flavor used to build this APK.
- `APPLICATION_ID`, which is the name that serves as the application ID (i.e., it includes build type suffixes and product flavor overrides). This is useful for cases where you cannot just call `getPackageName()` on a `Context` because you do not have a handy `Context`.
- `VERSION_CODE`, which is the version code derived from your manifest in conjunction with any overrides coming from your `build.gradle` file.
- `VERSION_NAME`, which is the version name derived from your manifest in conjunction with any overrides coming from your `build.gradle` file.

However, you can add your own data members to `BuildConfig`, by including a `buildConfigField` statement in the `defaultConfig` closure of your `android` closure:

```
android {
  defaultConfig {
    buildConfigField "int", "FOO", '5'
  }
}
```

You can use this to embed any sort of information you want into `BuildConfig`, so long as it is knowable at compile time.

Moreover, you can also have `buildConfigField` statements in build types. This would be useful if you have custom build types, beyond just debug and release, and you need runtime configuration for those. For example, you could put server URLs in `buildConfigField`, so your debug server is different from your integration test server, which in turn is different than your production server.

For example, in the chapter on SSL, we will see a sample app for demonstrating network security configuration, a way that apps can restrict their Internet access (e.g., require SSL for everything) and support custom SSL certificates (e.g., self-signed certificates for an internal test server). The `Internet/CA` sample project that we will see there has a long list of product flavors, and each of them defines a particular server URL to test against:

```
apply plugin: 'com.android.application'

def WARES='"https://wares.commonsware.com/excerpt-7p0.pdf"'
def SELFSIGNED='"https://scrap.commonsware.com:3001/excerpt-7p0.pdf"'

android {
    compileSdkVersion 27
    buildToolsVersion '27.0.3'

    defaultConfig {
        minSdkVersion 17
        targetSdkVersion 27
    }

    flavorDimensions "default"

    productFlavors {
        comodo {
            dimension "default"
            resValue "string", "app_name", "CA Validation Demo"
            applicationId "com.commonsware.android.downloader.ca.comodo"
            manifestPlaceholders=
                    [networkSecurityConfig: 'network_comodo']
            buildConfigField "String", "URL", WARES
        }
        verisign {
            dimension "default"
            resValue "string", "app_name", "Invalid CA Validation Demo"
            applicationId "com.commonsware.android.downloader.ca.verisign"
            manifestPlaceholders=
                    [networkSecurityConfig: 'network_verisign']
            buildConfigField "String", "URL", WARES
        }
```

```
        system {
            dimension "default"
            resValue "string", "app_name", "System CA Validation Demo"
            applicationId "com.commonsware.android.downloader.ca.system"
            manifestPlaceholders=
                    [networkSecurityConfig: 'network_verisign_system']
            buildConfigField "String", "URL", WARES
        }
        pin {
            dimension "default"
            resValue "string", "app_name", "Cert Pin Demo"
            applicationId "com.commonsware.android.downloader.ca.pin"
            manifestPlaceholders=
                    [networkSecurityConfig: 'network_pin']
            buildConfigField "String", "URL", WARES
        }
        invalidPin {
            dimension "default"
            resValue "string", "app_name", "Cert Pin Demo"
            applicationId "com.commonsware.android.downloader.ca.invalidpin"
            manifestPlaceholders=
                    [networkSecurityConfig: 'network_invalid_pin']
            buildConfigField "String", "URL", WARES
        }
        selfSigned {
            dimension "default"
            resValue "string", "app_name", "Self-Signed Demo"
            applicationId "com.commonsware.android.downloader.ca.ss"
            manifestPlaceholders=
                    [networkSecurityConfig: 'network_selfsigned']
            buildConfigField "String", "URL", SELFSIGNED
        }
        override {
            dimension "default"
            resValue "string", "app_name", "Debug Override Demo"
            applicationId "com.commonsware.android.downloader.ca.debug"
            manifestPlaceholders=
                    [networkSecurityConfig: 'network_override']
            buildConfigField "String", "URL", SELFSIGNED
        }
    }
}

repositories {
    maven {
        url "https://s3.amazonaws.com/repo.commonsware.com"
    }
}
```

```
dependencies {
    implementation 'com.android.support:support-v13:27.0.2'
    implementation 'com.commonsware.cwac:provider:0.5.3'
    implementation 'com.commonsware.cwac:netsecurity:0.4.4'
}
```

(from Internet/CA/app/build.gradle)

In this case, to reduce repetition, the two possible values are defined as globals and are poured into `BuildConfig.URL` via the `buildConfigField` statements.

Testing with JUnit4

Presumably, you will want to test your code, beyond just playing around with it yourself by hand. Android offers several means of testing your app, covered in this next series of chapters.

The first Android SDK testing solution we will examine is the JUnit test framework. This is a standard Java unit testing framework. Originally, Android itself "baked in" a copy of JUnit3. This has since been deprecated, and modern Android testing is done with a separate copy of JUnit4, in the form of a `AndroidJUnitRunner` class.

In this chapter, we will review how to apply the `AndroidJUnitRunner` to run JUnit4 tests for our Android apps.

Prerequisites

Understanding this chapter requires that you have read the core chapters of the book.

This chapter also assumes you have some familiarity with JUnit, though you certainly do not need to be an expert. You can learn more about JUnit at the JUnit site.

Instrumentation Tests and Unit Tests

There are two places in Android app development where we use JUnit4: instrumentation tests and unit tests. Both serve the same objective: confirm that our code runs as expected. What differs in where the code lives (`androidTest` versus

`test` source sets) and where the code runs (inside of Android or on your development machine directly).

The following sections outline the differences between the two, though there is a separate chapter dedicated to unit testing, with the bulk of this chapter focused on instrumentation testing.

Where Your Test Code Lives

One common problem with testing is determining where the test code should reside, relative to the production code being tested. Ideally, these are not intermingled, as that would increase the odds that you might accidentally ship the testing code as part of your production app — at best, this increases your APK size; at worst, it could open up security flaws.

With Gradle-based projects, including those created for Android Studio, we have a dedicated source set for our instrumentation tests, named `androidTest`, where the code for those tests would reside.

As with any source set, `androidTest` can have Java code, resources, etc. It does not need an `AndroidManifest.xml` file, though, as that will be auto-generated.

Unit tests, by contrast, will go in a `test` source set.

Where Your Test Code Runs

Ordinarily, each code base (e.g., project) is packaged in its own APK and is executed in its own process.

In the case of instrumentation tests, your test code and your production code are combined into a single process in a single copy of the virtual machine.

This will allow your JUnit test methods to access objects from your production code, such as your activities and their widgets.

However, this does limit instrumentation testing to be run from a developer's computer. You cannot package JUnit tests to be initiated from the device itself, except perhaps on rooted devices.

Unit tests, on the other hand, bypass Android and run straight on your development machine. As a result, they cannot use much of the Android SDK, and so these tests

are limited in terms of what they can test. However, they will run much more quickly, and so it may be worthwhile to set up a subset of your tests as unit tests.

Writing JUnit4 Test Cases

As noted in the intro to the chapter, modern Android testing — both instrumentation testing and unit testing — is done through JUnit4.

This book does not attempt to cover all aspects of JUnit4. For that, you are encouraged to read the JUnit documentation or other books on Java testing. This chapter will cover some of the basics of using JUnit4 tests, plus some of the issues with using JUnit4 tests in Android.

The Class

In JUnit terminology, "test case" is a Java class that represents a set of tests to run.

Any Java class can serve as a test case, so long as it has a zero-argument public constructor and is known to the test runner that it contains tests to be run. In the case of JUnit4 on Android, that comes via a `@RunWith(AndroidJUnit4.class)` annotation on the class, to signal that this class contains tests:

```
@RunWith(AndroidJUnit4.class)
public class ICanHazTests {
  // test code goes here
}
```

The Test Methods

In JUnit, a "test method" is a method, in a test case, that tests something in some production code base.

In JUnit4, a test method is any public method that is annotated with the `@Test` annotation:

```
@RunWith(AndroidJUnit4.class)
public class ICanHazTests {
  @Test
  public void kThxBye() {
    // do some testing
  }
}
```

A test method can then execute code to see if it works, and "assert" some conditions ("the response from the `foo()` method should be `1`"). JUnit4 supplies an `Assert` class with static assertion methods that we can employ:

```
@RunWith(AndroidJUnit4.class)
public class SillyTest {
  @Test
  public void thisIsReallySilly() {
    Assert.assertEquals("bit got flipped by cosmic rays", 1, 1);
  }
}
```

`assertEquals()` takes either two parameters of the same type for comparison (e.g., two `int` values), or three parameters, where the first is a custom assertion failure message.

There are countless other methods on `Assert` (e.g., `assertNotNull()`) for testing objects, collections, etc.

Setup and Teardown

A JUnit test case can also have methods that represent "setup" and "teardown" work. A "setup" method is one that executes before test methods and helps establish a common environment to be used by all of the test methods. A "teardown" method is one that is run after test methods and is used to clean up things created by the "setup" method. The objective is to ensure that each test method has a consistent and expected environment (e.g., contents of databases).

In JUnit4, you can annotate methods with `@Before` and `@After` for per-test-method setup and teardown work. The `@Before` method will be invoked before each test method is called; the `@After` method will be invoked after each test method is called.

JUnit4 also offers static `@BeforeClass` and `@AfterClass` methods, which are invoked once for the entire test case, designed for setting up immutable starter data for test methods and avoiding the overhead of doing that work on each test method invocation.

The `Testing/JUnit4` sample project illustrates the basics of setting up JUnit4 instrumentation tests.

We start off with a test case that is, well, silly:

```
package com.commonsware.android.abf.test;

import android.support.test.runner.AndroidJUnit4;
import junit.framework.Assert;
import org.junit.After;
import org.junit.AfterClass;
import org.junit.Before;
import org.junit.BeforeClass;
import org.junit.Test;
import org.junit.runner.RunWith;

@RunWith(AndroidJUnit4.class)
public class SillyTest {
  @BeforeClass
  static public void doThisFirstOnlyOnce() {
    // do initialization here, run once for all SillyTest tests
  }

  @Before
  public void doThisFirst() {
    // do initialization here, run on every test method
  }

  @After
  public void doThisLast() {
    // do termination here, run on every test method
  }

  @AfterClass
  static public void doThisLastOnlyOnce() {
    // do termination here, run once for all SillyTest tests
  }

  @Test
  public void thisIsReallySilly() {
    Assert.assertEquals("bit got flipped by cosmic rays", 1, 1);
  }
}
```

(from Testing/JUnit4/app/src/androidTest/java/com/commonsware/android/abf/test/SillyTest.java)

All we have is a single test method — `thisIsReallySilly()` — that validates that 1 really does equal 1. Fortunately, this test usually succeeds. Our `SillyTest` also implements `@Before`, `@After`, `@BeforeClass`, and `@AfterClass` methods for illustration purposes, as there is little preparation needed for our rigorous and demanding test method.

Testing Activities

JUnit4 offers "test rules", which are packaged bits of reusable code for testing certain scenarios. For example, the Android `rules` artifact has an `ActivityTestRule` to help you test your activities.

For example, `DemoActivityRuleTest` tests an activity from the main app, where the activity has a `ListView` with 25 Latin words in it:

```
package com.commonsware.android.abf.test;

import android.support.test.rule.ActivityTestRule;
import android.support.test.runner.AndroidJUnit4;
import android.widget.ListView;
import com.commonsware.android.abf.ActionBarFragmentActivity;
import junit.framework.Assert;
import org.junit.Before;
import org.junit.Rule;
import org.junit.Test;
import org.junit.runner.RunWith;

@RunWith(AndroidJUnit4.class)
public class DemoActivityRuleTest {
  private ListView list=null;
  @Rule public final ActivityTestRule<ActionBarFragmentActivity> main
      =new ActivityTestRule(ActionBarFragmentActivity.class, true);

  @Before
  public void init() {
    list=(ListView)main.getActivity().findViewById(android.R.id.list);
  }

  @Test
  public void listCount() {
    Assert.assertEquals(25, list.getAdapter().getCount());
  }
}
```

(from Testing/JUnit4/app/src/androidTest/java/com/commonsware/android/abf/test/DemoActivityRuleTest.java)

The `@Rule` annotation tells JUnit4 that this data member represents a JUnit4 rule that should be applied to the tests in this test case. `ActivityRuleTest` takes over the work of creating and destroying an instance of our `ActionBarFragmentActivity` as part of standard `@Before` and `@After` processing. The `true` in the `ActivityTestRule` constructor simply indicates that we want the activity to start off in touch mode.

We then use a `@Before` method to retrieve the `ListView` itself. We retrieve the activity created by the rule by calling `getActivity()` on the rule itself (here called `main`). Anything that is `public` on our activity — including most of the methods that we inherit from `Activity` — is usable here, such as `findViewById()`.

Our test method — `listCount()` — just confirms that our `ListAdapter` has 25 items in it.

Testing Context-Dependent Code

Sometimes, you do not need an activity, just some `Context`, for testing code that takes one as input (e.g., file I/O, database I/O, resources, assets). In those cases, you can just create a plain JUnit4 test case, but use the `InstrumentationRegistry` to get at a suitable `Context` for your test methods.

Specifically, wherever you need a `Context` tied to your app that you are testing, call `InstrumentationRegistry.getTargetContext()`.

The `InstrumentationRegistry` also has `getInstrumentation()` (which returns the `Instrumentation` object that we are using for testing) and `getContext()` (which returns the `Context` for our test code's package).

`DemoContextTest` demonstrates this:

```
package com.commonsware.android.abf.test;

import android.support.test.InstrumentationRegistry;
import android.support.test.runner.AndroidJUnit4;
import android.test.AndroidTestCase;
import android.test.UiThreadTest;
import android.view.LayoutInflater;
import android.view.View;
import com.commonsware.android.abf.R;
import junit.framework.Assert;
import org.junit.Before;
import org.junit.Test;
import org.junit.runner.RunWith;

@RunWith(AndroidJUnit4.class)
public class DemoContextTest {
  private View field=null;
  private View root=null;

  @Before
```

```
  public void init() {
    InstrumentationRegistry.getInstrumentation().runOnMainSync(new Runnable() {
      @Override
      public void run() {
        LayoutInflater inflater=LayoutInflater
            .from(InstrumentationRegistry.getTargetContext());

        root=inflater.inflate(R.layout.add, null);
      }
    });

    root.measure(800, 480);
    root.layout(0, 0, 800, 480);

    field=root.findViewById(R.id.title);
  }

  @Test
  public void exists() {
    Assert.assertNotNull(field);
  }

  @Test
  public void position() {
    Assert.assertEquals(0, field.getTop());
    Assert.assertEquals(0, field.getLeft());
  }
}
```

(from Testing/JUnit4/app/src/androidTest/java/com/commonsware/android/abf/test/DemoContextTest.java)

Here, we manually inflate the contents of the `res/layout/add.xml` resource, and lay them out as if they were really in an activity, via calls to `measure()` and `layout()` to simulate a WVGA800 display. At that point, we can start testing the widgets inside of that layout, from simple assertions to confirm that they exist, to testing their size and position.

Note that the act of inflating the layout is performed inside a `Runnable`, which itself is passed to `runOnMainSync()` on an `Instrumentation`. `runOnMainSync()` says "run this code on the main application thread, then block the current thread until that code has completed". On some versions of Android, layout inflation needs to happen on the main application thread, and therefore the test is more reliable if we do that inflation via `runOnMainSync()`. Test methods themselves run on a background thread, not the main application thread.

Configuring Gradle

Beyond having test code, we also need to provide some configuration information to Gradle to allow us to run these tests, eventually.

The Test Dependency

First, you need to add a test dependency — a dependency that will only be used as part of instrumentation testing. That can be accomplished via an `androidTestImplementation` statement in the `dependencies` closure, instead of a `implementation` statement, to limit the scope of the dependency to the case where the `androidTest` source set is in use.

Specifically, we need the `com.android.support.test:rules` artifact from the Android Support Repository:

```
dependencies {
    implementation "com.android.support:support-fragment:27.0.2"
    androidTestImplementation 'com.android.support.test:rules:1.0.1'
    androidTestImplementation 'com.android.support.test.espresso:espresso-core:3.0.1'
}
```

(from Testing/JUnit4/app/build.gradle)

As of the time of this writing, the latest version of this artifact is `0.5`.

However, the `rules` artifact also depends upon some other artifacts available in public repositories, like Maven Central or Bintray's JCenter. If you have one of those set up already — and a typical Android Studio project will via the top-level `build.gradle` file — then Gradle will be able to search those repositories for the dependencies.

The Test Runner

A "test runner", in JUnit terms, is a piece of code that knows how to plug into JUnit, execute tests, and collect any exceptions or assertion failures that result from those tests.

JUnit4 uses a test runner named `AndroidJUnitRunner`, which we gain access to through the aforementioned test dependency.

In the `defaultConfig` closure, we can teach Gradle to use that test runner, via the `testInstrumentationRunner` value:

```
android {
    compileSdkVersion 27
    buildToolsVersion '27.0.3'

    defaultConfig {
        minSdkVersion 15
        targetSdkVersion 27
        testApplicationId "com.commonsware.android.gradle.hello.test"
        testInstrumentationRunner "android.support.test.runner.AndroidJUnitRunner"
    }
}
```

(from Testing/JUnit4/app/build.gradle)

The Test Application ID

That `defaultConfig` closure also specifies a `testApplicationId`. This is a replacement value for our `applicationId` when we are running our tests. This allows our test build to run without disturbing any other builds (e.g., standard `debug` builds) on our test device or emulator.

The convention is to have the `testApplicationId` be your regular `applicationId` (or `package` from your `<manifest>`) with `.test` on the end, but that is merely a convention.

Running Your Instrumentation Tests

Writing tests is nice. Running tests is nicer. Hence, it would be useful if we could run our JUnit4 tests.

Android Studio Ad-Hoc Test Runs

You have few options for quickly running one of your instrumentation tests.

In the Android Studio editor for your test case, each test method will have a green “run” icon in the gutter. Clicking that will run that test method on your chosen device or emulator:

```
    @Test
    public void listCount() {
      Assert.assertEquals(25, list.getAdapter().getCount());
    }
}
```

Figure 347: Android Studio Per-Method Test Option

You can also right-click over a test case class, or a Java package containing test cases, and choose to run the tests cases from the context menu:

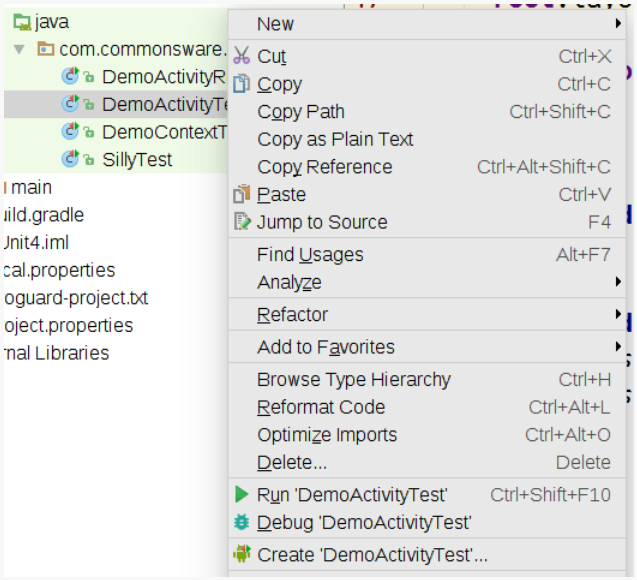

Figure 348: Android Studio Per-Class or Per-Package Test Option

Android Studio Run Configuration

You will see your ad-hoc runs appear in the drop-down list to the left of the run button in the Android Studio toolbar. That drop-down list represents your "run configurations", and you can set one of those up yourself directly if you wish.

To do that, choose Run > "Edit Configurations" from the main menu. That will bring up a dialog showing your current run configurations:

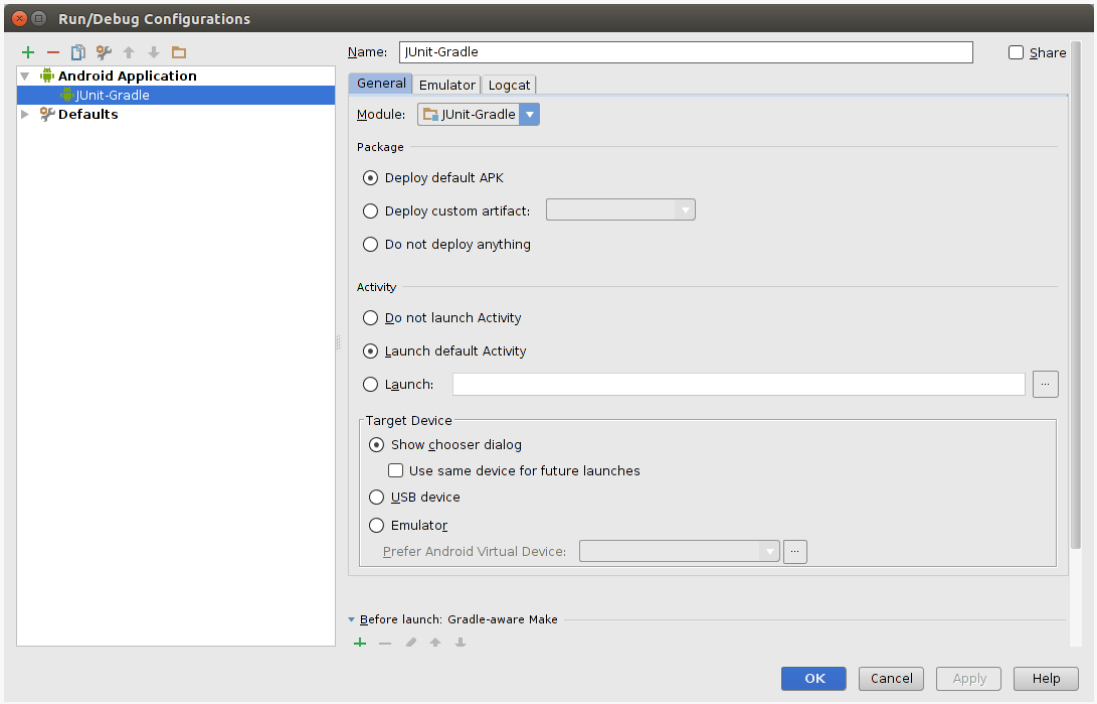

Figure 349: Android Studio Run Configurations Dialog

Towards the upper-left corner of the dialog, you will see a green plus sign. Tapping that will drop down a list of configuration types to choose from:

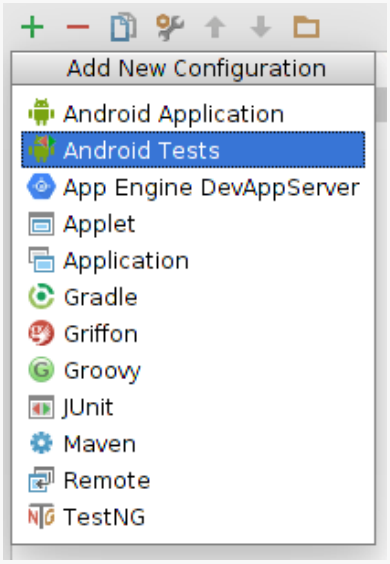

Figure 350: Android Studio, Adding a New Run Configuration

Choose “Android Instrumented Tests”, and a new empty configuration will be set up for you. You can name it whatever you want via the “Name” field (e.g., “Instr Tests”). Choose your project’s module that you wish to test in the “Module” drop-down (e.g., app). You can also choose the scope of the testing (e.g., “All in Module”), where to run the tests (e.g., “Show chooser dialog”), plus other settings.

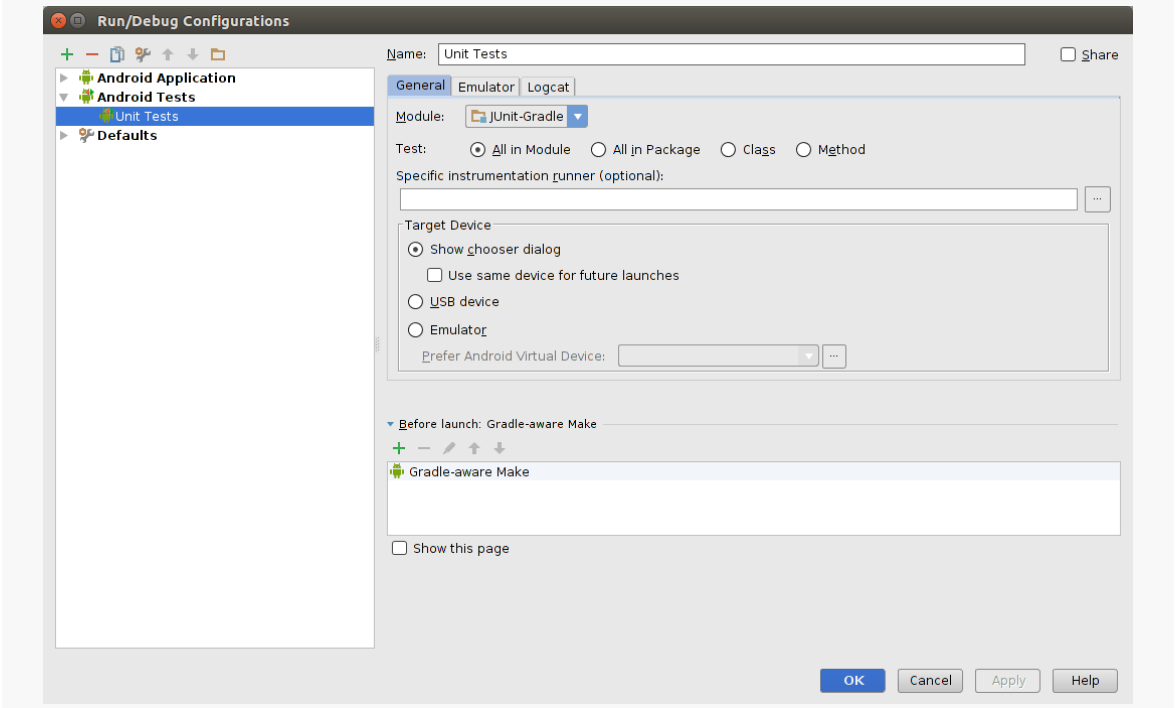

Figure 351: Android Studio, Showing New “Tests” Run Configuration

At that point, you can choose your run configuration from the drop-down to the left of the “play” button in the toolbar:

Figure 352: Android Studio Toolbar, Showing “Tests” Run Configuration

Note that the context menu for a class or package containing test cases has a “Create ...” option for creating a test run configuration specific for that class or package.

Examining the Test Results

Regardless of how you run the tests, the output will be shown in the Run view, normally docked in the bottom of your IDE window:

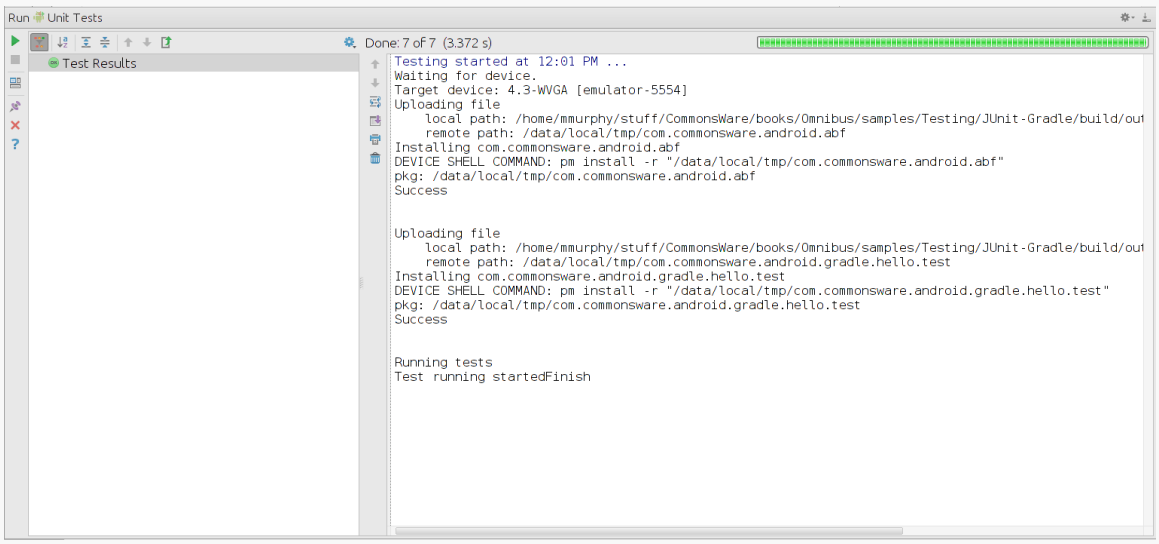

Figure 353: Android Studio, Showing Run Unit Tests Results

If a test fails an assertion or crashes, the test results will show the test case and test method that failed, along with the associated stack trace:

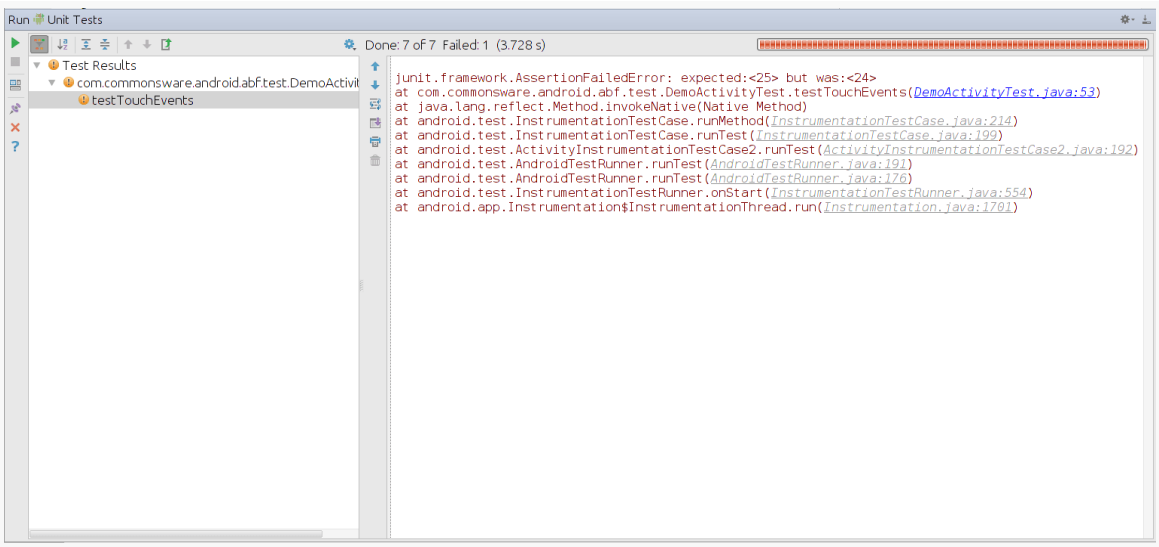

Figure 354: Android Studio, Showing Run Unit Tests Results With a Failure

Gradle for Android

The primary Gradle task that you will use related to testing is `connectedCheck`. This task will build the main app, then, build the test app (using a generated manifest to go along with the code from your `androidTest` source set).

At that point, the task will iterate over *all* compatible connected devices and running emulator instances. For each such Android environment, the task will install both apps, run the tests, and uninstall both apps.

Raw test results, in XML format, will be written to `build/outputs/androidTest-results/connected`. These will primarily be of interest to toolsmiths, such as those adding support for Android Gradle-based builds to continuous integration (CI) servers.

For others, the HTML reports will be of greater use. These will be written to `build/outputs/reports/androidTests/connected`, with an `index.html` file serving as your entry point. These will show the results of all of your tests, with hyperlinked pages to be able to "drill down" into the details, such as to investigate failed tests.

Testing Android Library Projects

The above procedures are aimed at testing Android application projects. If you are creating an Android library project, you can also use JUnit for testing.

A Gradle-built Android library project can have an `androidTest` source set, just like a regular app. And, a Gradle-built Android library project can be tested via the `connectedCheck` task. However, that task will create and install a single APK, consisting of the code from the `androidTest` source set combined with the library project's own code.

From the standpoint of what you do as a developer, though, it works just like testing an app: add your test cases to the `androidTest` source set and use `connectedCheck` to run the tests.

Testing and Runtime Permissions

Android 6.0 added the concept of runtime permissions, where permissions with a `protectionLevel` of `dangerous` are not granted automatically, but instead need to be

requested at runtime. Those requests result in a system-supplied dialog appearing, one that the user is supposed to tap on to grant or deny your request.

Our instrumentation tests cannot interact with this dialog. Moreover, our test code is its own separate app, and the first time it is installed, it will not have the runtime permissions yet. Hence, if we try testing code that needs those permissions, our tests fail.

There are two major approaches for dealing with this. If you wish to test the actual UI flow of your runtime permission request logic, you will need to use UiAutomator to simulate user clicks on the permission dialog. If, however, your instrumentation tests are focused on logic beneath the UI layer, you can grant the permissions yourself in your test code, bypassing any need for the dialog.

This is merely a matter of having the following code snippet in your test classes:

```
if (Build.VERSION.SDK_INT>=Build.VERSION_CODES.M) {
  InstrumentationRegistry
    .getInstrumentation()
    .getUiAutomation()
    .executeShellCommand(String.format("pm grant %s
android.permission.READ_EXTERNAL_STORAGE",
      target.getPackageName()));
}
```

Here, you would replace `READ_EXTERNAL_STORAGE` with whatever runtime permission you need, and execute multiple commands if you need to grant multiple permissions.

If you put this in `@BeforeClass`-annotated methods on your test case classes that need runtime permissions, you will minimize the amount of time spent executing this command, while ensuring that the runtime permissions are granted by the time your test methods exercise code that needs those permissions.

The Android Test Orchestrator

By default, when we run our instrumentation tests, Android forks a single process and runs all the tests in that process. This has two problems:

1. Results from previous tests might affect later tests. For example, perhaps a later test would have caught a bug, but only if some `static` field were not initialized... and it was initialized in some earlier test.

2. If we crash with an unhandled exception, particularly in a background thread, our test suite may terminate.

Quietly released in 2017, the Android Test Orchestrator addresses this by running each test method in its own separate process. This clears up these two problems, though it adds quite a bit of overhead. In particular, anything that you do in a custom `Application` subclass, such as in its `onCreate()` method, now happens for *every test method*, rather than just once for each run of your tests.

For Android Studio and Gradle-based tests, setting up the Android Test Orchestrator is fairly straightforward:

- Make sure that you are using `1.0.1` or higher of the `com.android.support.test:runner` library
- Add `androidTestUtil 'com.android.support.test:orchestrator:1.0.1'` to your `dependencies`, where the version number should match that of the `com.android.support.test:runner` dependency:

```
dependencies {
    implementation "com.android.support:support-fragment:27.0.2"
    androidTestImplementation 'com.android.support.test:runner:1.0.1'
    androidTestUtil 'com.android.support.test:orchestrator:1.0.1'
    androidTestImplementation 'com.android.support.test.espresso:espresso-core:3.0.1'
}
```

(from Testing/Orchestrator/app/build.gradle)

- Add a `testOptions` closure to the `android` closure of your module's `build.gradle` file, requesting the `execution` of `ANDROID_TEST_ORCHESTRATOR`:

```
android {
    compileSdkVersion 27
    buildToolsVersion '27.0.3'

    defaultConfig {
        minSdkVersion 15
        targetSdkVersion 27
        testApplicationId "com.commonsware.android.gradle.hello.test"
        testInstrumentationRunner "android.support.test.runner.AndroidJUnitRunner"
    }

    testOptions {
        execution 'ANDROID_TEST_ORCHESTRATOR'
    }
}
```

(from Testing/Orchestrator/app/build.gradle)

And that's it. There are no Java code changes required — you write your tests normally.

The Testing/Orchestrator sample project is cloned from the `JUnit4` sample, with the aforementioned changes, plus a custom `Application` class:

```
package com.commonsware.android.abf;

import android.app.Application;
import android.util.Log;

public class ScrapApp extends Application {
  @Override
  public void onCreate() {
    super.onCreate();

    Log.e("Frosty the Snowman", "Happy Birthday!");
  }
}
```

(from Testing/Orchestrator/app/src/main/java/com/commonsware/android/abf/ScrapApp.java)

Without the Android Test Orchestrator, the "Happy Birthday!" message would appear once in LogCat for the entire test suite. With the Android Test Orchestrator, the message appears once for each test method... and, inexplicably, an eighth time as well:

```
12-18 07:38:11.356 11131-11131/com.commonsware.android.abf E/Frosty the Snowman:
Happy Birthday!
12-18 07:38:12.438 11159-11159/com.commonsware.android.abf E/Frosty the Snowman:
Happy Birthday!
12-18 07:38:14.023 11213-11213/com.commonsware.android.abf E/Frosty the Snowman:
Happy Birthday!
12-18 07:38:15.358 11260-11260/com.commonsware.android.abf E/Frosty the Snowman:
Happy Birthday!
12-18 07:38:18.454 11316-11316/com.commonsware.android.abf E/Frosty the Snowman:
Happy Birthday!
12-18 07:38:19.809 11366-11366/com.commonsware.android.abf E/Frosty the Snowman:
Happy Birthday!
12-18 07:38:20.711 11392-11392/com.commonsware.android.abf E/Frosty the Snowman:
Happy Birthday!
12-18 07:38:21.635 11418-11418/com.commonsware.android.abf E/Frosty the Snowman:
Happy Birthday!
```

The downside comes in the speed of the tests. Running this short suite under the Android Test Orchestrator is noticeably slower than running the suite without the

Orchestrator. A test suite measuring in the thousands of test methods will result in a fair bit of additional overhead, forking thousands of processes instead of just one.

Testing with Espresso

Basic JUnit4 instrumentation tests are fine for testing non-UI logic. They even work acceptably for some basic UI testing. The more complex your UI testing gets, though, the more likely it is that you will find plain JUnit4 instrumentation tests to be limiting and tedious.

In particular, running tests across activities can be tricky with ordinary JUnit4. `ActivityTestRule` is designed for testing a single activity in isolation, and crafting your own rule that transcends a single activity may be difficult.

Espresso is designed to simplify otherwise-complex UI testing scenarios, such as:

- Testing across activities, such as confirming that tapping a `ListView` row in one activity correctly launches a detail activity associated with the model object for that row
- Testing over time, such as waiting for a list to be populated from a database before actually testing it

In this chapter, we will explore how to set up basic Espresso tests and how to employ them as part of your overall testing implementation.

Prerequisites

This chapter assumes that you have read the chapter on JUnit4.

Adding a Shot of Espresso

The Testing/Espresso sample project is the home of several test cases that employ Espresso, so we can see how it works in practice.

The app/ module's build.gradle file is fairly conventional, reminiscent of our JUnit4 equivalent, except that we have several dependencies:

```
apply plugin: 'com.android.application'

dependencies {
    implementation "com.android.support:support-fragment:27.0.2"
    androidTestImplementation 'com.android.support:support-annotations:27.0.2'
    androidTestImplementation 'com.android.support:recyclerview-v7:27.0.2'
    androidTestImplementation 'com.android.support.test.espresso:espresso-core:3.0.1'
    androidTestImplementation 'com.android.support.test.espresso:espresso-contrib:3.0.1'
    implementation 'com.android.support:recyclerview-v7:27.0.2'
}

android {
    compileSdkVersion 27
    buildToolsVersion '27.0.3'

    defaultConfig {
        minSdkVersion 15
        targetSdkVersion 27
        applicationId "com.commonsware.android.espresso"
        testApplicationId "com.commonsware.android.espresso.test"
        testInstrumentationRunner "android.support.test.runner.AndroidJUnitRunner"
        testInstrumentationRunnerArguments disableAnalytics: 'true'
    }

    packagingOptions {
        exclude 'LICENSE.txt'
    }
}
```

(from Testing/Espresso/app/build.gradle)

The sample app has activities for a ListView and a RecyclerView, and so we implementation in the recyclerview-v7 dependency for that reason. However, beyond that, there are four androidTest dependencies, to pull in things needed for instrumentation testing.

The big one is espresso-core, which contains the bulk of the Espresso test engine. Through Gradle's transitive dependencies, pulling in espresso-core also pulls in other key testing artifacts, such as:

- com.android.support.test:runner
- com.android.support.test:rules

- `com.android.support:support-annotations`
- `junit:junit` (indirectly, via `com.android.support.test:runner`)

Hence, just by asking for `espresso-core`, we pull in everything that we need not only for basic Espresso testing but also for general JUnit4-style instrumentation testing.

However, the `support-annotations` requested by `espresso-core` is an older version than the one that we are using in our code under test. So, we specifically pull in the newer `support-annotations`, allowing Gradle's dependency resolution to handle the version discrepancy.

The `espresso-contrib` and `recyclerview-v7` `androidTest` dependencies are for testing `RecyclerView`. Those artifacts will be discussed later in this chapter.

The test cases themselves still reside in the `androidTest/` source set and still use `@RunWith(AndroidJUnit4.class)`. Those aspects of instrumentation testing have not changed, just because we are using Espresso. And we are able to write classic Espresso-free instrumentation tests as well — we are not forced to use Espresso for everything, just because Espresso is part of our environment. So, for example, `SillyTest` in this sample project is the same as before:

```
package com.commonsware.android.abf.test;

import android.support.test.runner.AndroidJUnit4;
import junit.framework.Assert;
import org.junit.After;
import org.junit.AfterClass;
import org.junit.Before;
import org.junit.BeforeClass;
import org.junit.Test;
import org.junit.runner.RunWith;

@RunWith(AndroidJUnit4.class)
public class SillyTest {
  @BeforeClass
  static public void doThisFirstOnlyOnce() {
    // do initialization here, run once for all SillyTest tests
  }

  @Before
  public void doThisFirst() {
    // do initialization here, run on every test method
  }
```

```
  @After
  public void doThisLast() {
    // do termination here, run on every test method
  }

  @AfterClass
  static public void doThisLastOnlyOnce() {
    // do termination here, run once for all SillyTest tests
  }

  @Test
  public void thisIsReallySilly() {
    Assert.assertEquals("bit got flipped by cosmic rays", 1, 1);
  }
}
```

(from Testing/Espresso/app/src/androidTest/java/com/commonsware/android/abf/test/SillyTest.java)

Writing Tests in Espresso

Writing Espresso tests is often described as having three main steps:

1. Find the widgets you want to examine or manipulate
2. Perform actions on those widgets where needed (and where possible)
3. Check to see if widgets have a certain state

Finding Widgets via Hamcrest Matchers

Technically speaking, with Espresso, we do not "find widgets", though it is often simplest to phrase it that way. A more accurate description would be "obtain a `ViewInteraction` object that pertains to a particular widget". The `ViewInteraction` object in turn allows us to perform actions on the underlying widget and check the widget to see if it has a certain state.

For simple widgets — basically, ones that do not involve any sort of collection adapter, like a `ListView` — you can try to get the `ViewInteraction` object via the static `onView()` method on the `Espresso` class. However, the convention is to use a static import for `onView()`:

```
import static android.support.test.espresso.Espresso.onView;
```

(from Testing/Espresso/app/src/androidTest/java/com/commonsware/android/abf/test/DemoActivityRuleTest.java)

This allows you to simply call `onView()` as if it were some global function, rather than having to put `Espresso.` on the front of each occurrence.

The parameter to `onView()` is a `Matcher`. `Matcher` does not come from the Android SDK. Rather, it comes from the Hamcrest project. Another transitive dependency that we get automatically when we pull in Espresso is Hamcrest's matcher library.

There are three main sources of matchers that you can use:

1. `ViewMatcher` contains a number of `static` methods that return matchers that find a `View` with some specific characteristic, such as `withId()` to find a `View` with a particular ID
2. Hamcrest's `Matchers` class has a series of `static` methods that return matchers that help you combine other matchers (e.g., `allOf()` to find a `View` that matches more than one criteria) or work with plain Java collections (e.g., `empty()` to match a collection that is empty)
3. Your own custom matchers, which we will explore later in this chapter

For `ViewMatcher` and `Matchers`, the pattern is to use static imports for their methods as well, such as this import of `withId()`:

```
import static android.support.test.espresso.matcher.ViewMatchers.withId;
```

(from Testing/Espresso/app/src/androidTest/java/com/commonsware/android/abf/test/DemoActivityRuleTest.java)

Here is an Espresso version of the `listCount()` test from the JUnit4 chapter, where we want to validate that a `ListView` contains 25 entries:

```
@Test
public void listCount() {
  onView(withId(android.R.id.list))
    .check(new AdapterCountAssertion(25));
}
```

(from Testing/Espresso/app/src/androidTest/java/com/commonsware/android/abf/test/DemoActivityRuleTest.java)

Ignoring the `check()` part for now, the `onView(withId(android.R.id.list))` part returns a `ViewInteraction` that is for a `View` whose ID is `android.R.id.list`.

Performing Actions

Given a `ViewInteraction`, one thing that you can do is ask it to `perform()` one or more actions, represented by `ViewAction` objects. The `ViewActions` (note the plural)

class contains a series of `static` methods that create `ViewAction` objects. And, once again, the pattern is to use static imports for those methods.

Here is an Espresso version of the `keyEvents()` test from the JUnit4 chapter, where we want to validate that pressing the down arrow key four times selects the proper row:

```
@Test
public void keyEvents() {
  onView(withId(android.R.id.list))
    .perform(pressKey(KeyEvent.KEYCODE_DPAD_DOWN),
      pressKey(KeyEvent.KEYCODE_DPAD_DOWN),
      pressKey(KeyEvent.KEYCODE_DPAD_DOWN),
      pressKey(KeyEvent.KEYCODE_DPAD_DOWN))
    .check(new ListSelectionAssertion(3));
}
```

(from Testing/Espresso/app/src/androidTest/java/com/commonsware/android/abf/test/DemoActivityRuleTest.java)

Ignoring the `check()` part for now, we retrieve the `ListView` using the same `onView()` code as before. Then, we `perform()` four actions generated by the `pressKey()` method on `ViewActions`:

```
import static android.support.test.espresso.action.ViewActions.pressKey;
```

(from Testing/Espresso/app/src/androidTest/java/com/commonsware/android/abf/test/DemoActivityRuleTest.java)

`pressKey()`, as you might expect, simulates a keypress, given the `KeyEvent`. Other popular actions include:

- `click()` to simulate a click event
- `typeText()` to simulate text entry into an `EditText`
- `scrollTo()` to scroll a `ScrollView` to the point where some view is visible
- `pressImeActionButton()`, to press the action button on the soft keyboard, to trigger whatever action is tied to that button

`perform()` will take care of all synchronization with the main application thread and will ensure that the activity is idle before and after these actions. `perform()` returns the `ViewInteraction`, so you can chain on other operations, such as `check()` calls.

Validating via Assertions… And Possibly More Matchers

Of course, the point behind writing tests is to see if something works or not. That is handled by calling `check()` on a `ViewInteraction`, passing in a `ViewAssertion`

that... well... asserts something. A `ViewAssertion` basically wraps the assertion calls that you might make directly in JUnit4, working with the `ViewInteraction` to confirm that the underlying `View` has some particular state.

Stock Assertions

Compared with the other two phases of writing an Espresso test, there is very little in the way of useful stock assertions.

The `ViewAssertions` class contains a few `static` methods that create `ViewAssertion` objects. The one that you will see most commonly is `matches()`, which asserts that there is now a `View` that matches some supplied matcher, using the same matchers that you might use for `onView()`. This is useful for trivial cases ("is there now a widget whose text is 'Foo Bar'?").

To work with `matches()`, Espresso comes with a number of other matcher implementations that do not match views, but rather match something else, such as:

- `CursorMatchers` returns matchers that match rows in a `Cursor`
- `PreferenceMatchers` returns matchers that match `Preference` objects from a `PreferenceScreen`
- `BoundedMatcher`, from which you can create your own custom matchers

In addition to `ViewAssertions`, Espresso has a few additional classes offering assertions, such as:

- `LayoutAssertions`, for asserting things about how widgets lay out (e.g., confirm these widgets do not overlap)
- `PositionAssertions`... *also* for asserting things about how widgets lay out (e.g., confirm this widget is to the left of this other widget)

Custom Assertions

Since Espresso itself does not provide much in the way of assertions, and since there are few Espresso libraries to help, often you will have to write your own assertions to complete your tests.

This is a matter of writing a class that implements `ViewAssertion` and implements the `check()` method. `check()` receives two parameters:

- the `View` for which you are asserting some state
- a `NoMatchingViewException`, explaining why the first parameter is `null`, if the view could not be found to use with this assertion

Your job in `check()` is to perform ordinary JUnit4-style assertion checks on the `View`, **without modifying the `View`**. This latter part could be tricky, in that you do not necessarily know what does and does not modify the `View`. In general, the "do not modify the `View`" rule is a best-efforts attempt.

With that in mind, let's look at some `ViewAssertion` implementations.

The `listCount()` test method shown above references an `AdapterCountAssertion`:

```
@Test
public void listCount() {
  onView(withId(android.R.id.list))
    .check(new AdapterCountAssertion(25));
}
```

(from Testing/Espresso/app/src/androidTest/java/com/commonsware/android/abf/test/DemoActivityRuleTest.java)

`AdapterCountAssertion` assumes that it will be given an `AdapterView` and should assert that the underlying count matches a particular value:

```
static class AdapterCountAssertion implements ViewAssertion {
  private final int count;

  AdapterCountAssertion(int count) {
    this.count=count;
  }

  @Override
  public void check(View view,
                    NoMatchingViewException noViewFoundException) {
    Assert.assertTrue(view instanceof AdapterView);
    Assert.assertEquals(count,
      ((AdapterView)view).getAdapter().getCount());
  }
}
```

(from Testing/Espresso/app/src/androidTest/java/com/commonsware/android/abf/test/DemoActivityRuleTest.java)

The first thing that `check()` should do is assert whether the passed-in `View` is of the appropriate type. Then, it can safely down-cast the `View` as needed and perform the

"real" assertion. In this case, `AdapterCountAssertion` holds onto a `count` from its constructor and compares that to `getCount()` of the adapter in the `AdapterView`.

The `keyEvents()` test method referenced a `ListSelectionAssertion`:

```
@Test
public void keyEvents() {
  onView(withId(android.R.id.list))
    .perform(pressKey(KeyEvent.KEYCODE_DPAD_DOWN),
      pressKey(KeyEvent.KEYCODE_DPAD_DOWN),
      pressKey(KeyEvent.KEYCODE_DPAD_DOWN),
      pressKey(KeyEvent.KEYCODE_DPAD_DOWN))
    .check(new ListSelectionAssertion(3));
}
```

(from Testing/Espresso/app/src/androidTest/java/com/commonsware/android/abf/test/DemoActivityRuleTest.java)

`ListSelectionAssertion` does the same basic thing as does `AdapterCountAssertion`, except it that it validates that the `View` is a `ListView` and compares a known value to `getSelectedItemPosition()`:

```
static class ListSelectionAssertion implements ViewAssertion {
  private final int position;

  ListSelectionAssertion(int position) {
    this.position=position;
  }

  @Override
  public void check(View view,
                    NoMatchingViewException noViewFoundException) {
    Assert.assertTrue(view instanceof ListView);
    Assert.assertEquals(position,
      ((ListView)view).getSelectedItemPosition());
  }
}
```

(from Testing/Espresso/app/src/androidTest/java/com/commonsware/android/abf/test/DemoActivityRuleTest.java)

The combination of the test methods themselves and these custom assertions is significantly more verbose than the equivalent code using ordinary JUnit4 instrumentation testing:

```
@Test
public void listCount() {
  Assert.assertEquals(25, list.getAdapter().getCount());
```

```
}

@Test
public void keyEvents() {
  sendKeys("4*DPAD_DOWN");
  Assert.assertEquals(4, list.getSelectedItemPosition());
}
```

(from Testing/JUnit4/app/src/androidTest/java/com/commonsware/android/abf/test/DemoActivityTest.java)

However, custom assertions can be reused, so while Espresso adds a fair bit of overhead to small projects, the savings may add up over larger ones.

The Espresso Test Recorder

The Espresso Test Recorder in Android Studio lets you interact with your app on a device or emulator, while the Recorder makes notes of what you click on and writes skeleton Espresso tests for you. The level of GUI testing that you get is very shallow, but it is exceptionally easy to use.

Starting and Recording

The Run > Record Espresso Test option from the Android Studio main menu will kick off the Recorder, after asking you to choose a device or emulator on which to run the app. Your app is run inside the debugger, and an initially-empty “Record Your Test” window appears:

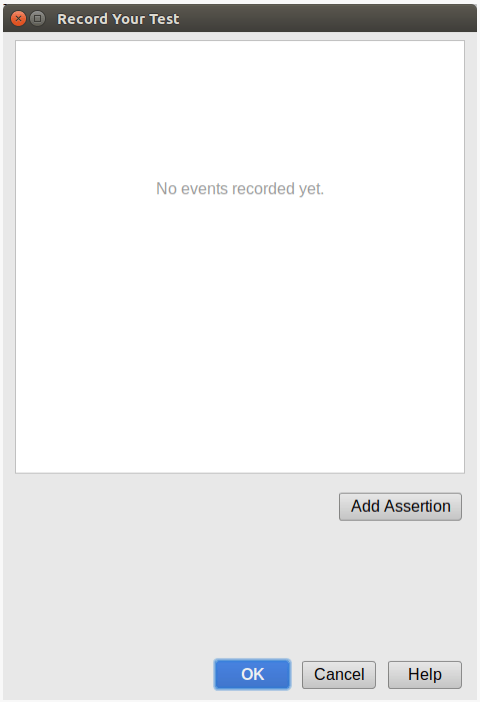

Figure 355: Espresso Test Recorder Events Window, As Initially Launched

As you tap on widgets in your UI, in addition to those taps doing whatever they normally do, events are recorded in that window:

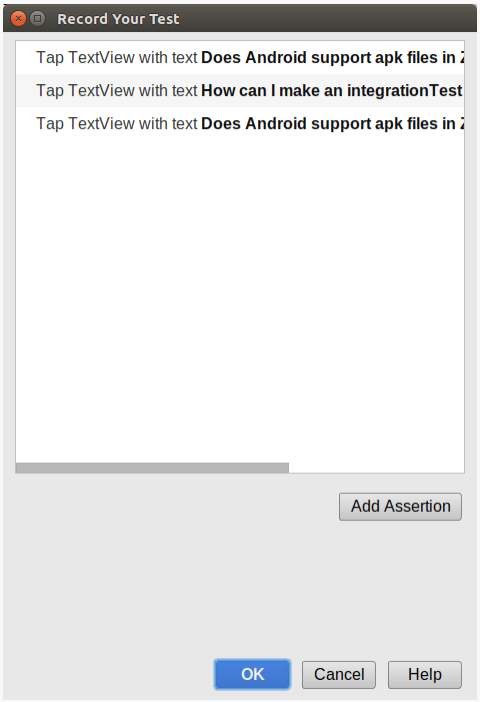

Figure 356: Espresso Test Recorder Events Window, With Some Events

Once you have the app in a state that you want to validate, click the "Add Assertion" button. This captures a screenshot, albeit one that is rotated, if your device or emulator is in landscape mode:

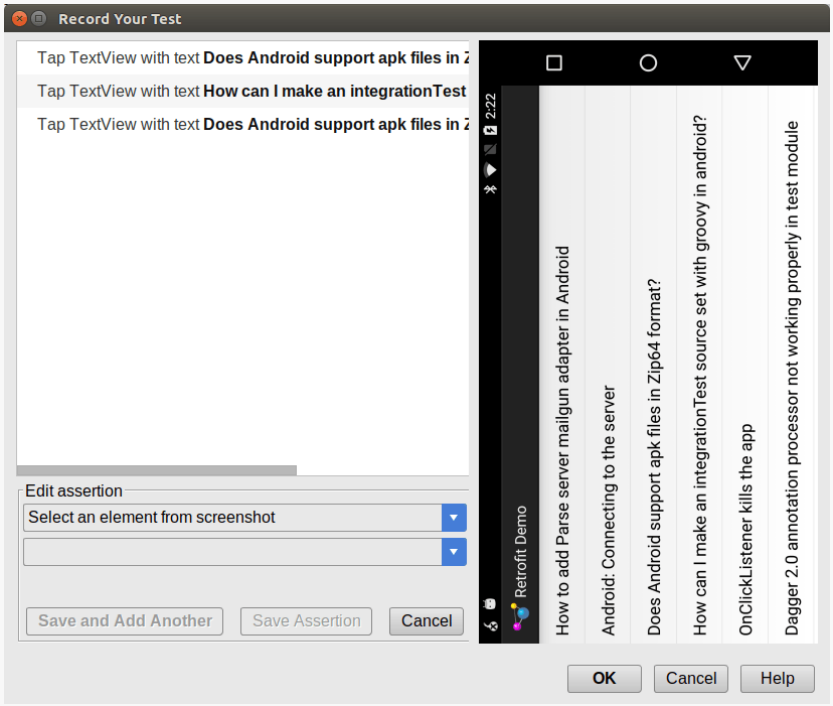

Figure 357: Espresso Test Recorder Events Window, After "Add Assertion" Clicked

A rotated screenshot is unusable; at the present time, the Recorder only really works if your device is in portrait mode.

To add an assertion, you must first click on a widget *in the screenshot* that you want to validate. Alternatively, you can choose the widget from the "Select an element from screenshot" drop-down list.

Then, the second drop-down will allow you to choose what specific assertion you want to apply:

- "text is", to match the text of some `TextView` (or subclass) with its current value
- "exists"
- "does not exist" (which seems odd, considering that it must exist for you to be able to use this dialog)

Clicking "Save and Add Another" adds the assertion and lets you define another one right away:

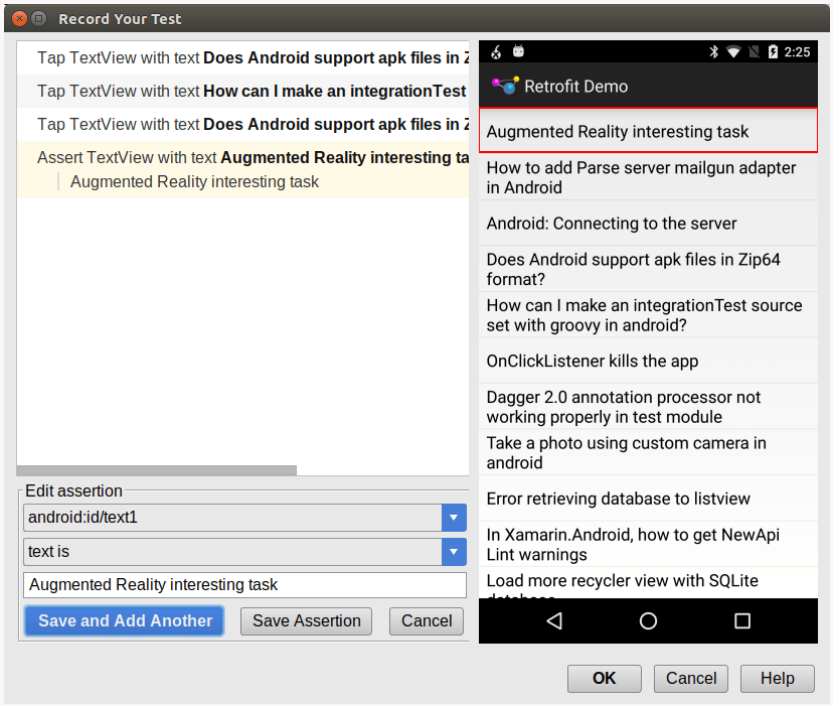

Figure 358: Espresso Test Recorder Events Window, With One Assertion

Clicking "Save Assertion" adds the assertion and returns you to the original screenshot-less rendition of the dialog.

Click OK in the "Record Your Test" dialog to save and apply the recording. You will be prompted for a name to give the JUnit4 test class. Also, if your project is not already set up for Espresso, you will be prompted as to whether or not the Recorder should add Espresso to your Gradle build files.

What You Get

The resulting class will contain:

- An `ActivityTestRule` for the activity that you tested
- A test method, named after the activity (e.g., `mainActivityTest()`) that contains the Espresso code to validate the activity
- Utility methods as needed by the test method

Is This Worthwhile?

Probably not, at least with the edition of the Recorder in Android Studio 2.3.

The Recorder:

- Does not handle `ListView` well
- Supports few types of assertions, as noted above
- Does not support landscape mode while recording, as noted above
- Does not do a very good job of uniquely identifying widgets, resulting in lots of `AmbiguousViewMatcherException` crashes when you run the tests
- And so on

However, this tool may be fine for trivial user interfaces, and the tool may improve in future versions of Android Studio.

Stronger Espresso

You can craft some basic tests using the above techniques, even some not-so-basic tests. However, Espresso offers a fair bit more depth, to tackle more complex testing scenarios.

This chapter does not offer complete coverage of Espresso, skipping many topics like testing `WebView` using the WebDriver Atom system. That being said, here are some more advanced uses of Espresso that you may need in your testing.

Testing AdapterView

`AdapterView` gets complicated because the views that you want to test may or may not exist in the state that you are expecting. Your targeted `ListView` row, for example, may require scrolling and some row recycling before it exists.

Espresso has a slightly different syntax for testing `AdapterView`, to take this into account. Instead of `onView()`, you use `onData()`. Whereas `onView()` takes a `Matcher` that identifies the view to be tested, `onData()` takes a `Matcher` that identifies the specific view state in some item of an `AdapterView` to be tested. However, there are other approaches that one can take to use `onData()`.

In the sample app, `scrollToBottom()` in `DemoActivityRuleTest` tries to confirm that the last position has the proper last word:

```
@Test
public void scrollToBottom() {
  onData(anything())
    .inAdapterView(withId(android.R.id.list))
```

```
      .atPosition(24)
      .check(matches(withText("purus")));
  }
```

(from Testing/Espresso/app/src/androidTest/java/com/commonsware/android/abf/test/DemoActivityRuleTest.java)

The `Matcher` that we provide into `onData()` is `anything()`, which, as the name suggests, matches anything. However, we constrain which item to test via `atPosition(24)`, specifying a particular row in the list based on its position.

`onData()` will work on the first `AdapterView` that it finds, since many activities only have one at most. `inAdapterView()` allows you to identify the specific `AdapterView` that `onData()` should work with.

The `DataInteraction` that `onData()` creates — and is modified by `inAdapterView()` and `atPosition()` — supports the same sort of `check()` semantics as does the `ViewInteraction` returned by `onView()`. Here, we use `matches()` to create our assertion, to confirm that the view identified by the `DataInteraction` has the word that should appear at the end of our list.

Testing RecyclerView

`RecyclerView` is similar enough to `AdapterView` that you might think that you would use `onData()` to work with its contents.

In a word, no.

Instead, you use the same `onView()` that you use for regular widgets. In fact, at the time of this writing, the only thing that Espresso offers specific to `RecyclerView` is `RecyclerViewActions`, which knows how to scroll to a particular item or position, perform actions on items or positions, and so forth.

The `RecyclerViewTest` class tests a `RecyclerView`, from the `MainActivity` in the `rv` sub-package of the sample app. That `MainActivity`, in turn, is cloned from the `ManualDividerList` sample covered in the chapter on `RecyclerView`. It is similar to the `ListView` that we tested earlier in this chapter, showing a vertical-scrolling list of 25 Latin words.

One wrinkle with `MainActivity`, and its `RecyclerViewActivity` base class, is that the `RecyclerView` has no ID. Espresso is *much* easier to use when you have widgets with IDs. There are a couple of ways to get a view with no ID, illustrated in `RecyclerViewTest`.

The `RecyclerView` variant of the `listCount()` test, to confirm that the list has 25 entries, uses one approach to find the `RecyclerView`: the `instanceOf()` method from the standard Hamcrest matchers:

```
@Test
public void listCount() {
  onView(Matchers.<View>instanceOf(RecyclerView.class))
    .check(new AdapterCountAssertion(25));
}
```

(from Testing/Espresso/app/src/androidTest/java/com/commonsware/android/abf/test/RecyclerViewTest.java)

`instanceOf()` takes the Java class you are seeking as a parameter, and it tries to find an Object that matches that class. However, `instanceOf()` returns a `Matcher` for `Object`, and we need a `Matcher` for `View` to satisfy `onView()`. That is what triggers our need for the complex type-specific call to `instanceOf()`, where we tell `Matchers` that we want the `View`-typed version of `instanceOf()`.

`onView()` with `instanceOf()` gives us a `ViewInteraction` on the `RecyclerView`. Our revised `AdapterCountAssertion` checks the `RecyclerView.Adapter` in the `RecyclerView` to validate the number of items:

```
static class AdapterCountAssertion implements ViewAssertion {
  private final int count;

  AdapterCountAssertion(int count) {
    this.count=count;
  }

  @Override
  public void check(View view,
                    NoMatchingViewException noViewFoundException) {
    Assert.assertTrue(view instanceof RecyclerView);
    Assert.assertEquals(count,
      ((RecyclerView)view).getAdapter().getItemCount());
  }
}
```

(from Testing/Espresso/app/src/androidTest/java/com/commonsware/android/abf/test/RecyclerViewTest.java)

The `RecyclerView` variant of `scrollToBottom()` is going to simply confirm that we can successfully scroll to position 24 — if the list is shorter than this, we will fail to scroll to that position and have an exception:

```
  @Test
  public void scrollToBottom() {
    onView(withClassName(is(RecyclerView.class.getCanonicalName())))
      .perform(scrollToPosition(24))
      .check(matches(anything()));
  }
```

(from Testing/Espresso/app/src/androidTest/java/com/commonsware/android/abf/test/RecyclerViewTest.java)

This time, to find the `RecyclerView`, we use `withClassName()`. This is a method on `ViewMatchers`, and so it gives us the appropriately-typed `Matcher` for use with `onView()`. However, instead of taking a Java class, it takes a `Matcher` of `String` as a parameter. The `is()` method from the standard Hamcrest matchers returns a `Matcher` that uses `equals()` to compare a supplied value (in this case, the fully-qualified class name for `RecyclerView`). So, `withClassName(is(...))` will find the view of the designated class given the supplied class name.

Once again, `onView()` is returning a `ViewInteraction` on the `RecyclerView`. In `perform()`, we use `scrollToPosition()`, from `RecyclerViewActions`, to scroll the `RecyclerView` to position 24. `RecyclerViewActions` itself is not part of the core Espresso dependency, though. We need to add a dependency on `espresso-contrib` instead, as is shown in the module's `build.gradle` file:

```
apply plugin: 'com.android.application'

dependencies {
    implementation "com.android.support:support-fragment:27.0.2"
    androidTestImplementation 'com.android.support:support-annotations:27.0.2'
    androidTestImplementation 'com.android.support:recyclerview-v7:27.0.2'
    androidTestImplementation 'com.android.support.test.espresso:espresso-core:3.0.1'
    androidTestImplementation 'com.android.support.test.espresso:espresso-contrib:3.0.1'
    implementation 'com.android.support:recyclerview-v7:27.0.2'
}

android {
    compileSdkVersion 27
    buildToolsVersion '27.0.3'

    defaultConfig {
        minSdkVersion 15
        targetSdkVersion 27
        applicationId "com.commonsware.android.espresso"
        testApplicationId "com.commonsware.android.espresso.test"
        testInstrumentationRunner "android.support.test.runner.AndroidJUnitRunner"
        testInstrumentationRunnerArguments disableAnalytics: 'true'
    }

    packagingOptions {
        exclude 'LICENSE.txt'
    }
}
```

(from Testing/Espresso/app/build.gradle)

However, `espresso-contrib` depends on an older version of `recyclerview-v7`, so we manually use `androidTestImplementation` to pull in the same version of `recyclerview-v7` that we are using for the "production" code.

Back in `scrollToBottom()`, the `ViewInteraction` created with `onView()` and modified via `perform()` is for the `RecyclerView` itself, not the 25th item. Hence, with this structure, we cannot readily check to see if the 25th item has the proper text. Instead, we settle for ensuring that it matches `anything()`, relying on an exception if for some reason we cannot get to position 24.

Intent Testing

Another optional dependency, `espresso-intents`, allows you to create what amount to mocks and stubs for activities to be started from your code under test. Rather than actually starting those activities, you can intercept the `Intent` that would have been used for `startActivity()` or `startActivityForResult()`, to see if it contains what it should. And, you can provide mock responses to be delivered to `onActivityResult()` for testing `startActivityForResult()` behaviors.

The `Testing/EspressoIntents` sample project is a clone of the `ConfigChange/Bundle` sample app from earlier in the book. It has two buttons, Pick and View. Tapping the Pick button will allow the user to pick a contact out of the list of contacts. Picking a contact then enables the View button, which allows the user to view the selected contact. In instrumentation testing, we want to confirm that the Pick button works as expected.

This app's `build.gradle` file pulls in `espresso-intents` as well as `espresso-core`:

```
apply plugin: 'com.android.application'

dependencies {
    androidTestImplementation 'com.android.support:support-annotations:25.0.3'
    androidTestImplementation 'com.android.support.test.espresso:espresso-core:2.2.2'
    androidTestImplementation 'com.android.support.test.espresso:espresso-intents:2.2.2'
}

android {
    compileSdkVersion 24
    buildToolsVersion '26.0.2'

    defaultConfig {
        minSdkVersion 14
        targetSdkVersion 22
        testApplicationId "com.commonsware.android.rotation.bundle.test"
        testInstrumentationRunner "android.support.test.runner.AndroidJUnitRunner"
```

```
        testInstrumentationRunnerArguments disableAnalytics: 'true'
    }

    packagingOptions {
        exclude 'LICENSE.txt'
    }
}
```

(from Testing/EspressoIntents/app/build.gradle)

The `IntentTests` class in the `androidTest` source set contains four test methods, two of which are focused on the pick button and its results. This requires the `IntentTests` class to use a different `@Rule`: `IntentsTestRule`:

```
  @Rule
  public final IntentsTestRule<RotationBundleDemo> main
    =new IntentsTestRule(RotationBundleDemo.class, true);
```

(from Testing/EspressoIntents/app/src/androidTest/java/com/commonsware/android/rotation/bundle/IntentTests.java)

`IntentsTestRule` extends `ActivityTestRule`, so on the whole it behaves the same. However, it has additional hooks for testing `startActivity()` and `startActivityForResult()` with mocks and stubs.

One of the test methods is `canceledPick()`, designed to test what happens if the user presses BACK and exits the contact-picker activity:

```
  @Test
  public void canceledPick() {
    Instrumentation.ActivityResult result=
      new Instrumentation.ActivityResult(Activity.RESULT_CANCELED,
        null);

    intending(hasAction(Intent.ACTION_PICK)).respondWith(result);

    onView(withId(R.id.pick)).perform(click());

    intended(allOf(
      toPackage("com.google.android.contacts"),
      hasAction(Intent.ACTION_PICK),
      hasData(ContactsContract.Contacts.CONTENT_URI)));

    onView(withId(R.id.view)).check(matches(not(isEnabled())));
  }
```

(from Testing/EspressoIntents/app/src/androidTest/java/com/commonsware/android/rotation/bundle/IntentTests.java)

`intending()` is a method that we get from Espresso's `Intents` class. It works with the `IntentsTestRule` to set up a stub with a mock response for our `ACTION_PICK` request that the Pick button will invoke via `startActivityForResult()`. `intending()` takes a `Matcher` of `Intent` objects, identifying which request you are interesting in stubbing. Espresso's `IntentMatchers` class has a series of methods to help you construct an appropriate `Matcher`. In this case, we use `hasAction()` to find our `ACTION_PICK` request. `intending()` returns an oddly-named `OngoingStubbing` class, which represents the stub. On there, we call `respondWith()` to provide the result to feed to `onActivityResult()`. In this case, our response has `RESULT_CANCELED`, simulating the user pressing BACK to exit the contact picker.

We then click the Pick button, by finding it via `onView(withId(R.id.pick))`, then calling `perform()` to `click()` the button. This triggers our "production" code to call `startActivityForResult()`, where our stub delivers the mock response to `onActivityResult()`.

Then, we validate two things:

- First, did we actually send that `Intent`? `intended()` allows us to inspect what `startActivity()` and `startActivityForResult()` calls were made, to validate that it has the appropriate information.
- Second, is the View button still disabled? It starts off disabled, but if the user picks a contact, we enable it. In our case, we did not pick a contact, and so we want to ensure that the button stays disabled, using `matches(not(isEnabled()))`.

The `stubPick()` test method tests the opposite scenario, where the user picks a contact. This time, our result has to have `RESULT_OK` and a sufficiently-valid result `Intent`. In theory, we could have code here that looks up some random contact in `ContactsContract` and uses the `Uri` for it. In this case, all we need is for the result `Intent` to have a `Uri`, so we just use the `ContactsContract.Contacts.CONTENT_URI`:

```
@Test
public void stubPick() {
  Instrumentation.ActivityResult result=
    new Instrumentation.ActivityResult(Activity.RESULT_OK,
      new Intent(null, ContactsContract.Contacts.CONTENT_URI));

  intending(hasAction(Intent.ACTION_PICK)).respondWith(result);

  onView(withId(R.id.pick)).perform(click());
```

```
    intended(allOf(
      toPackage("com.google.android.contacts"),
      hasAction(Intent.ACTION_PICK),
      hasData(ContactsContract.Contacts.CONTENT_URI)));

    onView(withId(R.id.view)).check(matches(isEnabled()));
  }
```

(from Testing/EspressoIntents/app/src/androidTest/java/com/commonsware/android/rotation/bundle/IntentTests.java)

This time, though, the View button should be enabled, so we confirm that as part of our test result validation.

If you are looking to stub a `startActivity()` call, use `respondWith()` and any result. The result will wind up being ignored, but failing to use `respondWith()` does not result in the stub being created, and trying a `null` result crashes Espresso.

Testing Activity Re-Creation and Configuration Changes

Activities get destroyed and re-created by default as a result of a configuration change. You may want to test that process, to ensure that you are retaining the right state information, such as via the `onSavedInstanceState()` `Bundle`. You might even want to test specific configuration changes, such as to confirm that your layouts are set up properly after the user rotates the screen.

While the techniques outlined here can work with plain JUnit4 testing, Espresso simplifies the process a bit. A key challenge with testing this sort of scenario is knowing when the work for the configuration change is done, so you know it is time to go ahead and test the result. Espresso automatically monitors the work queue of the main application thread and only proceeds when the queue indicates that the device is idle, so you know that the configuration change is completed.

Testing the activity destroy-and-create cycle is mostly a matter of calling `recreate()` on the `Activity`. Strictly speaking, `recreate()` is not tied to testing — it is a regular method on `Activity` that you could call whenever. It has limited uses outside of testing, though, which is why you will not run across it very much.

The `recreate()` test method tests `recreate()` to confirm that our View button remains enabled after a destroy-and-recreate cycle:

```
  // inspired by http://stackoverflow.com/a/35139887/115145

  @Test
```

```
public void recreate() {
  stubPick();

  InstrumentationRegistry.getInstrumentation().runOnMainSync(new Runnable() {
    @Override
    public void run() {
      main.getActivity().recreate();
    }
  });

  onView(withId(R.id.view)).check(matches(isEnabled()));
}
```

(from Testing/EspressoIntents/app/src/androidTest/java/com/commonsware/android/rotation/bundle/IntentTests.java)

We first call `stubPick()`, to run through all the code that we tested separately for picking a contact. Then, on the main application thread (via `runOnMainSync()`), we call `recreate()` on the activity, which we get by calling `getActivity()` on our `IntentsTestRule`. Then, we can re-validate the enabled state of the `R.id.view` widget, to confirm that it is still enabled.

Testing a simulated screen rotation is decidedly more complex. Thanks to Chiu-ki Chan, we have a recipe to start with.

First, we need to know what our current orientation is:

```
private int getOrientation() {
  return(InstrumentationRegistry
    .getTargetContext()
    .getResources()
    .getConfiguration()
    .orientation);
}
```

(from Testing/EspressoIntents/app/src/androidTest/java/com/commonsware/android/rotation/bundle/IntentTests.java)

This gets the `orientation` field from the `Configuration` associated with our app under test (`InstrumentationRegistry.getTargetContext()`). That will be one of the `Configuration` values for orientation, such as `Configuration.ORIENTATION_LANDSCAPE`.

To simulate a screen rotation, we can call `setRequestedOrientation()` on the activity. This tells the activity to ignore the actual orientation based on sensors and to use this other orientation instead. Our `rotate()` utility method will flip the orientation from whatever it actually is (via `getOrientation()`) to the opposite:

```
private void rotate() {
  int target=
    (getOrientation()==Configuration.ORIENTATION_LANDSCAPE ?
      ActivityInfo.SCREEN_ORIENTATION_PORTRAIT :
      ActivityInfo.SCREEN_ORIENTATION_LANDSCAPE);

  main.getActivity().setRequestedOrientation(target);
}
```

(from Testing/EspressoIntents/app/src/androidTest/java/com/commonsware/android/rotation/bundle/IntentTests.java)

We also have a `testOrientation()` helper method:

```
private int testOrientation() {
  int orientation=getOrientation();

  if (orientation==Configuration.ORIENTATION_LANDSCAPE) {
    onView(withId(R.id.content))
      .check(new OrientationAssertion(LinearLayout.HORIZONTAL));
  }
  else {
    onView(withId(R.id.content))
      .check(new OrientationAssertion(LinearLayout.VERTICAL));
  }

  return(orientation);
}
```

(from Testing/EspressoIntents/app/src/androidTest/java/com/commonsware/android/rotation/bundle/IntentTests.java)

This finds our current orientation (via `getOrientation()`). Based upon that, it validates whether our `LinearLayout` has the correct orientation. To aid with this, the layouts now have an ID for the `LinearLayout` (`R.id.content`), so we do not have to go through messy code to try to find the right object. There is no built-in assertion for testing the orientation of a `LinearLayout`, but it is easy enough for us to write our own `OrientationAssertion`:

```
static class OrientationAssertion implements ViewAssertion {
  private final int orientation;

  OrientationAssertion(int orientation) {
    this.orientation=orientation;
  }

  @Override
  public void check(View view,
                    NoMatchingViewException noViewFoundException) {
```

```
    Assert.assertTrue(view instanceof LinearLayout);
    Assert.assertEquals(orientation,
      ((LinearLayout)view).getOrientation());
  }
}
```

(from Testing/EspressoIntents/app/src/androidTest/java/com/commonsware/android/rotation/bundle/IntentTests.java)

All that gets used by the `orientation()` `@Test` method:

```
@Test
public void orientation() {
  int original=testOrientation();

  rotate();

  int postRotate=testOrientation();

  Assert.assertFalse("orientation changed", original==postRotate);
}
```

(from Testing/EspressoIntents/app/src/androidTest/java/com/commonsware/android/rotation/bundle/IntentTests.java)

Here we:

- Test our current orientation, noting what orientation that is
- Simulate rotating the screen
- Test our new orientation, noting what orientation that is
- Validate that the orientation did actually change, using an ordinary JUnit4 assertion

Custom Matchers

Espresso has a robust set of `Matcher` implementations. Most likely, you will not need to create your own custom matcher. This is particularly true if you do a good job of putting `android:id` values on your widgets, so you can just use `withId()`.

That being said, it is certainly possible to create your own `Matcher`, if you really want to.

As Chiu-ki Chan points out, the key is to use `BoundedMatcher` as a base class. This creates a `Matcher` for some type (e.g., `View`) and subtype (e.g., `TextView`). The dual-typing appears to be due to some odd interactions between Espresso, Hamcrest, and Java generics.

The Testing/EspressoMatcher sample project is a clone of another sample app, this one using TextInputLayout from the Design Support library, covered elsewhere in the book. TextInputLayout is a wrapper around an EditText that provides the "floating label" pattern.

The actual "floating label" of a TextInputLayout comes from its hint. However, while Espresso has a withHint() matcher method, that is for TextView and subclasses. TextInputLayout does not inherit from TextView; it has its own clone of the hint-related methods (e.g., setHint()). If we want to find a TextInputLayout by hint, we need our own matcher.

The TILTest class in androidTest implements such a TILHintMatcher:

```
private static class TILHintMatcher
  extends BoundedMatcher<View, TextInputLayout> {
  private final Matcher<CharSequence> textMatcher;

  TILHintMatcher(Matcher<CharSequence> textMatcher) {
    super(TextInputLayout.class);

    this.textMatcher=textMatcher;
  }

  @Override
  protected boolean matchesSafely(TextInputLayout item) {
    return(textMatcher.matches(item.getHint()));
  }

  @Override
  public void describeTo(Description description) {
    description.appendText("with hint: ");
    textMatcher.describeTo(description);
  }
}
```

(from Testing/EspressoMatcher/app/src/androidTest/java/com/commonsware/android/design/til/TILTest.java)

TILHintMatcher is a subclass of BoundedMatcher, declaring that it is creating a Matcher of View, but where *really* the View should be a TextInputLayout. We use a Matcher of CharSequence as our identifier — we will use that to compare against the hint to see if a given TextInputLayout is the one that we want.

There are two methods that you need to implement on your BoundedMatcher subclass. The big one is matchesSafely(). This gives you an instance of your specific type (in this case, TextInputLayout). Your job is to return true if this widget

matches the rules for this matcher instance. In our case, we confirm that the hint of the `TextInputLayout` satisfies our `CharSequence` `Matcher`.

The other method is `describeTo()`. This builds up a description of the matcher, used for diagnostic purposes, such as in cases where more than one `View` matches. The pattern is to update the supplied `Description` object with details about your matching rule. Here, we indicate that we are checking to see if the hint matches the `textMatcher` rule.

The activity under test — `LaunchDemo` — has a `TextInputLayout` wrapped around a `TextInputEditText`, where the user can type in a URL. There is also a `browse` button that, when clicked, will open an `ACTION_VIEW` activity on that URL. We want to confirm that this works, using the `Intent` stub-and-mock approach outlined earlier in this chapter.

In this case, we need to:

- Enter some text into the `TextInputEditText`, then
- Click the `browse` button

This would be simplest if we just gave a unique ID to the `TextInputEditText`, but that will not test out a custom matcher. So, we go through a more complex approach, involving our `TILHintMatcher`:

```
@Test
public void til() {
  onView(allOf(withParent(withTILHint("URL")),
    Matchers.<View>instanceOf(TextInputEditText.class)))
    .perform(typeText(URL), closeSoftKeyboard());

  Instrumentation.ActivityResult result=
    new Instrumentation.ActivityResult(Activity.RESULT_CANCELED,
      null);

  intending(hasAction(Intent.ACTION_VIEW)).respondWith(result);

  onView(withId(R.id.browse)).perform(click());

  intended(allOf(hasAction(Intent.ACTION_VIEW), hasData(URL)));
}

private Matcher<View> withTILHint(CharSequence text) {
  return(new TILHintMatcher(is(text)));
}
```

(from Testing/EspressoMatcher/app/src/androidTest/java/com/commonsware/android/design/til/TILTest.java)

It is possible that we could have several `TextInputEditText` widgets in our layout. In truth, we do not. But, in case we elect to add more later, we do not want to simply look for an instance of `TextInputEditText`, as that may not be unique. Instead, we want to find the one that is a child of the `TextInputLayout` that has a hint of `"URL"`.

`withTILHint()` is a utility method that simply wraps a supplied string in an `is()` matcher, then creates a `TILHintMatcher` wrapped around that.

`withParent(withTILHint("URL"))`, therefore, is a matcher that matches any widget that has a parent that is a `TextInputLayout`, with a hint of `"URL"`.

You might think that would be sufficient, given our layout:

```
<?xml version="1.0" encoding="utf-8"?>
<LinearLayout xmlns:android="http://schemas.android.com/apk/res/android"
              android:layout_width="match_parent"
              android:layout_height="match_parent"
              android:orientation="vertical">

  <Button
    android:id="@+id/browse"
    android:layout_width="match_parent"
    android:layout_height="wrap_content"
    android:onClick="showMe"
    android:text="@string/show_me">

    <requestFocus/>
  </Button>

  <android.support.design.widget.TextInputLayout
    android:id="@+id/til"
    android:layout_width="match_parent"
    android:layout_height="wrap_content">

    <android.support.design.widget.TextInputEditText
      android:id="@+id/url"
      android:layout_width="match_parent"
      android:layout_height="wrap_content"
      android:hint="@string/url"
      android:inputType="textUri"/>
  </android.support.design.widget.TextInputLayout>

</LinearLayout>
```

(from Testing/EspressoMatcher/app/src/main/res/layout/main.xml)

As it turns out, `TextInputLayout` has its own internal structure. `onView(withParent(withTILHint("URL")))` will fail, indicating that more than one `View` matches.

So, we use Hamcrest's `allOf()` method, which creates a matcher that uses a boolean AND operation on all supplied matchers — all have to match for `allOf()` to consider it a match. So, we also use `instanceOf()` to constrain us to `TextInputEditText` widgets. That, finally, gives us our `TextInputEditText` widget, and makes us glad that we can use `android:id` in our own code and avoid all of this hassle.

To complete our testing, we call `perform()` to perform some actions on the `TextInputEditText`. `perform()` can execute any number of actions, and here we are performing two:

1. `typeText()`, to type in a URL (identified here as a `URL` constant)
2. `closeSoftKeyboard()`, to ensure that the soft keyboard has collapsed after testing

If we did not `perform()` `closeSoftKeyboard()`, the tests would work in portrait mode, but not in landscape, given the way that the full-screen landscape input method editor works.

We then:

- Set up to stub the `ACTION_VIEW` `Intent` request, with a throwaway response
- `click()` the `browse` button
- Validate that we did invoke an `ACTION_VIEW` `Intent` with the proper URL

Opting Out of Analytics

All of the `build.gradle` files shown in this chapter have the following line in `defaultConfig`:

```
testInstrumentationRunnerArguments disableAnalytics: 'true'
```

By default, your Espresso tests send data about your tests to Google. This line passes arguments to the test runner that disable these analytics.

Waiting for the World to Change

Our activities often trigger asynchronous work: loading data from a database, loading content from a `ContentProvider`, executing a Web service call, etc. Sometimes, that work is triggered by the start of the activity. Sometimes, that work is triggered by UI events.

Usually, our tests need to wait for that work to complete before we can proceed with confirming the results. For example, if tapping an action bar item refreshes the `RecyclerView` contents via some asynchronous work, we cannot determine whether or not the refresh worked until that asynchronous operation ends.

Even simpler things would seem to need more synchronization than we are writing in our tests. Let's go back to the `keyEvents()` test from earlier in this chapter:

```
@Test
public void keyEvents() {
  onView(withId(android.R.id.list))
    .perform(pressKey(KeyEvent.KEYCODE_DPAD_DOWN),
      pressKey(KeyEvent.KEYCODE_DPAD_DOWN),
      pressKey(KeyEvent.KEYCODE_DPAD_DOWN),
      pressKey(KeyEvent.KEYCODE_DPAD_DOWN))
    .check(new ListSelectionAssertion(3));
}
```

(from Testing/Espresso/app/src/androidTest/java/com/commonsware/android/abf/test/DemoActivityRuleTest.java)

We simulate four down-arrow presses, then check to see if the proper list row is selected.

However, `keyEvents()` runs on a background thread, not the main application thread. In theory, there is a race condition here: will the work associated with those four down-arrow events be completed by the time we go to check the selection state of the `ListView`?

It turns out that Espresso handles this automatically. It waits until the work queue for the main application thread shows that there is no more work ready to process. Then, and only then, will the `check()` logic be applied.

Espresso also waits on select other things, notably `AsyncTasks`. And, through an `IdlingResource`, we can teach it to wait for other asynchronous work: arbitrary threads, an `IntentService`, and so on.

What's an IdlingResource?

An `IdlingResource` is an interface. Implementations of it know how to monitor some background work for completion. You can register an `IdlingResource` with Espresso via `Espresso.registerIdlingResources()`, later removing it via `Espresso.unregisterIdlingResources()`.

An `IdlingResource` needs to do two main things:

1. Return whether the resource being monitored is idle at the moment, via an `isIdleNow()` method
2. Track a `ResourceCallback` instance and call an `onTransitionToIdle()` method on it when the resource becomes idle

Using an IdlingResource

In some cases, you will be able to use a pre-built `IdlingResource`.

Espresso itself comes with a `CountingIdlingResource` that you can use a bit like a `CountDownLatch`, calling `increment()` when work is added and `decrement()` when work is completed. When the counter falls to zero from a non-zero value, the `CountingIdlingResource` will call `onTransitionToIdle()` on its `ResourceCallback`. And, `isIdleNow()` is simply based on the counter.

Sometimes, you will find existing implementations from third parties. For example, Jake Wharton has written an `OkHttp3IdlingResource` for use with OkHttp3. The `Testing/EspressoIdle` sample project demonstrates its use.

The activity under test is a variation on the OkHttp3 "show the latest Stack Overflow questions" sample from the chapter on Internet access. That activity (`MainActivity`) holds an `OkHttpClient` instance to be used by its fragment, returned via a `getOkHttpClient()` method:

```
package com.commonsware.android.okhttp;

import android.support.v4.app.FragmentActivity;
import android.content.Intent;
import android.net.Uri;
import android.os.Bundle;
import okhttp3.OkHttpClient;

public class MainActivity extends FragmentActivity
  implements QuestionsFragment.Contract {
  private final OkHttpClient client=
```

```
    new OkHttpClient.Builder().build();

  @Override
  protected void onCreate(Bundle savedInstanceState) {
    super.onCreate(savedInstanceState);

    if (getSupportFragmentManager().findFragmentById(android.R.id.content) == null) {
      getSupportFragmentManager().beginTransaction()
                          .add(android.R.id.content,
                               new QuestionsFragment()).commit();
    }
  }

  @Override
  public void onQuestion(Item question) {
    startActivity(new Intent(Intent.ACTION_VIEW,
                             Uri.parse(question.link)));
  }

  OkHttpClient getOkHttpClient() {
    return(client);
  }
}
```

(from Testing/EspressoIdle/app/src/main/java/com/commonsware/android/okhttp/MainActivity.java)

`QuestionsFragment` then uses OkHttp3 to request the latest 100 Stack Overflow questions, parsing the JSON response with Gson, and loading them into the fragment's `ListView`. This is handled in the `onViewCreated()` method:

```
@Override
public void onViewCreated(final View view, Bundle savedInstanceState) {
  super.onViewCreated(view, savedInstanceState);

  OkHttpClient client=((MainActivity)getActivity()).getOkHttpClient();
  Request request=new Request.Builder().url(SO_URL).build();

  client.newCall(request).enqueue(new Callback() {
    @Override
    public void onFailure(Call call, IOException e) {
      Log.e(getClass().getSimpleName(), "Exception loading JSON", e);
    }

    @Override
    public void onResponse(Call call, Response response)
      throws IOException {
      if (response.isSuccessful()) {
        Reader in=response.body().charStream();
        BufferedReader reader=new BufferedReader(in);
        final SOQuestions questions=
          new Gson().fromJson(reader, SOQuestions.class);
```

```
        reader.close();

        view.post(new Runnable() {
          @Override
          public void run() {
            setListAdapter(new ItemsAdapter(questions.items));
          }
        });
      }
      else {
        Log.e(getClass().getSimpleName(), response.toString());
      }
    }
  });
}
```

(from Testing/EspressoIdle/app/src/main/java/com/commonsware/android/okhttp/QuestionsFragment.java)

Note that `onViewCreated()` uses `enqueue()`, rather than `execute()`, so the HTTP request is performed on an OkHttp3-supplied background thread. We do not know if this is an `AsyncTask` or some other type of thread, and so we do not know for certain if Espresso will know to wait until this request is complete. Hence, in our tests, we really should use an `IdlingResource` to confirm that the asynchronous work is completed before seeing if the results match our expectations.

The `OkHttpTests` instrumentation test class uses an `ActivityRule`, named `main`, to set up our activity under test. The `moreReliableAsyncTest()` method then uses `OkHttp3IdlingResource` to help out our test code:

```
@Test
public void moreReliableAsyncTest() {
  IdlingResource idleWild=
    OkHttp3IdlingResource.create("okhttp3",
      main.getActivity().getOkHttpClient());

  Espresso.registerIdlingResources(idleWild);

  try {
    onView(withId(android.R.id.list))
      .check(new AdapterCountAssertion(100));
  }
  finally {
    Espresso.unregisterIdlingResources(idleWild);
  }
}
```

(from Testing/EspressoIdle/app/src/androidTest/java/com/commonsware/android/okhttp/OkHttpTests.java)

An `IdlingResource` has a name, which needs to be unique among registered `IdlingResource` instances. So, we use `okhttp3`. `OkHttp3IdlingResource` also needs our `OkHttpClient`, which we can get by retrieving it from the `MainActivity`, which is available to us courtesy of the `main` `ActivityRule`.

We then:

- Call `registerIdlingResources()` to register our `OkHttp3IdlingResource`
- Perform our tests, to confirm that we got 100 items in the list
- Call `unregisterIdlingResource()`, as we can no longer use our `OkHttp3IdlingResource` once the activity is destroyed; any new activity instances will have their own `OkHttpClient` in our implementation

Implementing a Custom IdlingResource

A custom `IdlingResource` can be simple or complex, depending on how difficult it is to determine whether a resource is idling and when it starts idling.

In the case of `OkHttp3IdlingResource`, OkHttp3 itself exposes a API, in the form of a `Dispatcher` object, that provides an API ideal for an `IdlingResource`:

- A `Dispatcher` has `runningCallsCount()` for use by `isIdleNow()`
- A `Dispatcher` has `setIdleCallback()`, to be called when the running calls count drops to zero

In this case, the reason for the clean integration may be tied to the fact that Jake Wharton works on OkHttp3.

Sometimes, you have to use a less elegant approach, because the resource you wish to monitor does not offer an appropriate monitoring API. Chiu-ki Chan wrote an `IntentServiceIdlingResource` that uses `ActivityManager` to watch for when a specific `IntentService` implementation is no longer listed as a running service. There is no way to register a callback with Android to find out when an arbitrary service is destroyed, so she only invokes the `ResourceCallback` `onTransitionToIdle()` method as part of `isIdleNow()` processing.

Testing with UI Automator

Yet another approach for testing Android applications is UI Automator. This is designed for integration testing, both how your app components integrate with one another (e.g., activities starting activities) and how your app components integrate with the rest of a device, including other applications.

In early 2015, Google released version 2.0 of the UI Automator framework. This update ties UI Automator into the same instrumentation testing engine that is used for JUnit4 testing. This also makes it possible to run UI Automator tests through Android Studio and the Android Gradle Plugin, which previously had been difficult.

Prerequisites

This chapter assumes that you have read the chapter on JUnit4.

What Is UI Automator?

UI Automator, as the name suggests, automates UIs. It simulates user input, in the form of tapping on items and the like. It does so without modifying your process' contents. Tests run by UI Automator are implemented in JUnit, and those tests have limited access to the widgets inside of a UI. Such access not only allows for directing simulated user input (e.g., "click the OK button"), but also for asserting that various test conditions are true (e.g., "does the list have five rows?"). In this respect, UI Automator behaves like traditional Android JUnit testing.

Why Choose UI Automator Over Alternatives?

In some respects, UI Automator represents the worst of both worlds. You have to use JUnit, making test authoring a challenge for those not skilled with Java. Yet you only have fairly generic access to an activity's widgets, versus the complete white-box capability of normal instrumentation-based JUnit testing.

Hence, why would anyone bother?

The big thing that UI Automator offers over classic JUnit testing is greater ability to test an *application* versus testing *individual components*. The classic JUnit test cases are organized around testing some specific component, such as using `ActivityInstrumentationTestCase2` to exercise some specific activity. Testing the flow of work between activities is difficult from classic JUnit, but is relatively easy with UI Automator. You can also use this for integration testing, as you can exercise and analyze applications other than your own, such as to confirm that you are starting a third-party app correctly.

Similarly, classic JUnit testing cooks up activity instances "out of thin air". Instead, UI Automator executes normal UI operations to create the activities, such as tapping on your app's icon in the home screen launcher. This more accurately simulates what a user will do — users are far more likely to tap on a launcher than to hack into your Dalvik VM and manually instantiate an activity.

You can see a set of UI Automator tests in a suitable project in the `Testing/UiAutomator` directory. Note, though, that the UI Automator tests will only work successfully on Android 4.x emulators, and perhaps a few other environments. The tests are testing the integration of the home screen to the app, along with the app's functionality, and the particular code used to navigate the home screen will only work with the stock Android home screen, not necessarily any manufacturer's home screen or third-party home screen.

Gradle and Android Studio Settings

Your project needs to be set up to use the `AndroidJUnitRunner` as is outlined in the chapter on JUnit4.

For UI Automator, you additionally need to have an `androidTestImplementation` dependency on the `uiautomator-v18` artifact:

```
dependencies {
    androidTestCompile 'com.android.support.test:rules:0.3'
    androidTestCompile 'com.android.support.test.uiautomator:uiautomator-v18:2.1.0'
}
```

(from Testing/UiAutomator/app/build.gradle)

Here the `-v18` suffix, as with the regular Android Support package libraries, means that this only works on API Level 18 and higher.

If you wish to run the tests from Android Studio, you will also need to set up a run configuration, as outlined in the chapter on JUnit4.

Creating a Test Case

Your test case classes do not need to inherit from any particular base class, just like regular JUnit4 tests. They do need to be annotated with the `@RunWith(AndroidJUnit4.class)` annotation:

```
@RunWith(AndroidJUnit4.class)
public class ListTests {
```

(from Testing/UiAutomator/app/src/androidTest/java/com/commonsware/android/abf/uiautomator/ListTests.java)

Your test case is welcome to have `@Before`, `@After`, and other setup/teardown methods, in addition to `@Test` methods, just like a regular JUnit4 test case. In fact, from Android's standpoint, UI Automator tests *are* just regular JUnit4 test cases — you are welcome to have UI Automator test cases and regular instrumentation testing JUnit4 test cases in the same `androidTest` source set.

Performing Device-Level Actions

The root of most of our work with UI Automator is a `UiDevice` object. This allows us to perform device-level actions, such as pressing BACK or HOME.

To get a `UiDevice`, call the static `getInstance()` method on `UiDevice`, passing in the `Instrumentation` that you get from `InstrumentationRegistry.getInstrumentation()`:

```
  @Before
  public void setUp() throws UiObjectNotFoundException {
    device=UiDevice.getInstance(InstrumentationRegistry.getInstrumentation());
    openActivity();
  }
```

(from Testing/UiAutomator/app/src/androidTest/java/com/commonsware/android/abf/uiautomator/ListTests.java)

Here, we get the `UiDevice` and stash it in a data member for the life of this `ListTests` instance.

`UiDevice` has many methods that allow you to perform device-level actions, such as calling `pressHome()` to press the HOME button (and thereby bring up the home screen). Similarly, you can call:

- `pressBack()` and `pressMenu()` for the BACK and MENU buttons
- `pressDPadUp()`, `pressDPadLeft()`, etc. for D-pad events
- `pressRecentApps()` to bring up the recent tasks list
- `pressKeyCode()` to press an arbitrary key based on the keycode from `KeyEvent`

...and so on.

Inspecting and Interacting with the UI

Of course, pressing some buttons is not especially useful on its own, only as a means to an end, such as launching your activity. To do more than this, you will need to get your hands on widgets and containers, to perform operations related to them.

The key is that you can "get your hands on widgets and containers" *from whatever activity is in the foreground*. This is not limited to your own app, but rather works for *any* app, including the home screen itself.

The following sections will work through some common UI Automator operations, in the context of the `openActivity()` from the `ListTests` class in the sample project. This method, called from `setUp()`, consolidates the work to bring an instance of our production activity to the foreground, by means of interacting with the home screen:

```
private void openActivity() throws UiObjectNotFoundException {
  device.pressHome();

  UiObject allAppsButton=
      device.findObject(new UiSelector().description("Apps"));

  allAppsButton.clickAndWaitForNewWindow();

  UiObject appsTab=device.findObject(new UiSelector().text("Apps"));

  appsTab.click();
```

```
    UiScrollable appViews=
        new UiScrollable(new UiSelector().scrollable(true));

    appViews.setAsHorizontalList();

    UiObject ourApp=
        appViews.getChildByText(new UiSelector().className("android.widget.TextView"),
                                "Action Bar Fragment Demo");

    ourApp.clickAndWaitForNewWindow();

    UiObject appValidation=
        device.findObject(new UiSelector().packageName("com.commonsware.android.abf"));

    Assert.assertTrue("Could not open test app", appValidation.exists());
  }
```

(from Testing/UiAutomator/app/src/androidTest/java/com/commonsware/android/abf/uiautomator/ListTests.java)

Finding and Interacting with Widgets

`openActivity()` starts by calling `pressHome()` on the `UiDevice`, to ensure that the home screen is in the foreground:

```
    device.pressHome();
```

(from Testing/UiAutomator/app/src/androidTest/java/com/commonsware/android/abf/uiautomator/ListTests.java)

Next, we want to bring up the home screen's launcher, showing the available launchable activities, so that we can find our app and launch it. What a user would do, on a stock Android environment like an emulator, would be to click on the appropriate button to bring up the launcher. We need to do the same thing, except from our test code. This implies:

- Finding that widget
- Simulating a click of that widget

Web developers are used to finding DOM nodes by CSS queries. Developers using XML are used to using XPath queries to find particular elements. Along the same lines, UI Automator gives us a flexible system to find widgets in the foreground activity, by means of a `UiSelector` object, typically created using the public zero-argument constructor (i.e., `new UiSelector()`).

In CSS, a "selector" can identify DOM nodes by class, `id`, or ones with particular properties. A `UiSelector` can do much the same thing. So, the first `UiSelector` created in `openActivity()` will find a widget in the foreground activity whose "description" is `Apps` (`new UiSelector().description("Apps")`). Here, "description"

will mean either the text of a `TextView` or the `android:contentDescription` of other types of widgets.

How do we know that this particular button has a "description" of `Apps`? In this case, we found out using `uiautomatorviewer`, which will be discussed in a future update to this chapter.

By passing our `UiSelector` to `findObject()` on the `UiDevice`, we get a `UiObject` that, hopefully, knows how to interact with this particular button of the home screen. In particular, we call `clickAndWaitForNewWindow()` on it, which taps the button and blocks until something else (e.g., a new activity) has taken over the foreground:

```
    UiObject allAppsButton=
        device.findObject(new UiSelector().description("Apps"));

    allAppsButton.clickAndWaitForNewWindow();
```

(from Testing/UiAutomator/app/src/androidTest/java/com/commonsware/android/abf/uiautomator/ListTests.java)

The stock Android launcher has two tabs, one for apps and one for (app) widgets. We need to ensure that the apps tab is selected. So, once again, we create a `UiSelector` and use it to create a `UiObject` to represent the apps tab. This time, we use `text()` instead of `description()`. `text()` will find a widget based solely on its display text (e.g., `android:text` of a `TextView`). In truth, we could have used `description()` here as well, with the same results.

Then, we call `click()` on the `UiObject`, to simulate a tap on this tab, to ensure that is the selected tab.

```
    UiObject appsTab=device.findObject(new UiSelector().text("Apps"));

    appsTab.click();
```

(from Testing/UiAutomator/app/src/androidTest/java/com/commonsware/android/abf/uiautomator/ListTests.java)

Dealing with Collections

Finding widgets by text or description is fairly easy when there is only one possible widget that has that text or description. Things get more complicated when you are dealing with a collection of widgets, such as an `AdapterView`.

For example, the Apps tab of the standard Android launcher uses a `GridView` to show up to 20 launchable activities. Then, you need to swipe horizontally, courtesy of a `ViewPager`, to uncover additional `GridView` collections of launchable activities.

A `UiCollection` helps deal with this, in terms of allowing you to inspect a collection of widgets, including performing the necessary swipe operations to access all of the contents.

A `UiSelector` called with `scrollable(true)` will return a widget that is scrollable. Creating a `UiCollection` with that `UiSelector` will create a `UiCollection` around the first scrollable widget. In the case of the Apps tab, that will be the `ViewPager`-and-`GridView` combination.

In our case, to get to other elements in the collection, you need to swipe horizontally. To configure the `UiCollection` that way, we have to call `setAsHorizontalList()` on the `UiCollection`:

```
UiScrollable appViews=
    new UiScrollable(new UiSelector().scrollable(true));

appViews.setAsHorizontalList();

UiObject ourApp=
    appViews.getChildByText(new UiSelector().className("android.widget.TextView"),
                            "Action Bar Fragment Demo");
```

(from Testing/UiAutomator/app/src/androidTest/java/com/commonsware/android/abf/uiautomator/ListTests.java)

Finding Widgets By Type

In that collection, we want to find the item that contains our app's caption. This test project is designed to test the same sample app that was tested in the JUnit chapter, a slightly modified version of an early action bar sample. Our launcher entry's name will be "Action Bar Fragment Demo", as that is what we set up in the production project's manifest and string resources. So, we need to find the entry in the `ViewPager`-of-`GridViews` that has that title.

To do that, we will create yet another `UiSelector`. This time, though, we will find widgets by type, specifying `className("android.widget.TextView")` to only work with `TextView` widgets.

That `UiSelector` is passed into the `getChildByText()` method of `UiCollection`, which will iterate over the children to find the first one that matches the `UiSelector` and where the selected widget contains the supplied text:

```
    UiObject ourApp=
        appViews.getChildByText(new UiSelector().className("android.widget.TextView"),
                                "Action Bar Fragment Demo");
```

(from Testing/UiAutomator/app/src/androidTest/java/com/commonsware/android/abf/uiautomator/ListTests.java)

Then, we again call `clickAndWaitForNewWindow()`, to tap on our launcher entry, triggering our app's activity to come to the foreground:

```
    ourApp.clickAndWaitForNewWindow();
```

(from Testing/UiAutomator/app/src/androidTest/java/com/commonsware/android/abf/uiautomator/ListTests.java)

Asserting Conditions

`UiSelector` and `UiObject` can also be used for some operations that do not fit the normal widgets-and-containers pattern shown above.

For example, now that we have opened a window from our app to be tested, it would be nice to confirm that, indeed, this is our app, and that our `openActivity()` method did not open some other app by mistake.

To do this, we can create a `UiSelector` and apply `packageName()`, to constrain the selection to widgets coming from an app with our desired package name:

```
    UiObject appValidation=
        device.findObject(new UiSelector().packageName("com.commonsware.android.abf"));
```

(from Testing/UiAutomator/app/src/androidTest/java/com/commonsware/android/abf/uiautomator/ListTests.java)

The `UiObject` we create always exists (i.e., is not `null`), as we are creating it via the constructor. However, it is entirely possible that our `UiSelector` cannot match any widget, such as would be the case if we accidentally opened the wrong app and tried to find a widget stemming from our package. The `exists()` method on a `UiObject` returns `true` if the `UiObject` is pointing at an actual widget, `false` otherwise. Hence, we can assert that we indeed have a widget coming from our package:

```
    Assert.assertTrue("Could not open test app", appValidation.exists());
```

(from Testing/UiAutomator/app/src/androidTest/java/com/commonsware/android/abf/uiautomator/ListTests.java)

The net result is that we open our main activity and confirm that, indeed, that is what we opened.

And Now… The Real Test Methods

All of that was just to get the activity for testing onto the screen.

Now the *real* testing begins.

The `ListTests` class has two test methods, `testContents()` and `testAdd()`, designed to (lightly) exercise the UI.

testContents()

The objective of the `testContents()` method is to confirm that the 25 words all appear in the `ListView`.

To do that, we:

- Create a `UiScrollable` for a `UiSelector` that finds the `ListView` in our activity
- Mark that `UiScrollable` as being a vertical list, where swipes up and down will expose the various children
- Iterate over the array of words, finding the `TextView` for each word and confirming that this widget does indeed exist

```
@Test
public void testContents() throws UiObjectNotFoundException {
  UiScrollable words=
      new UiScrollable(
                      new UiSelector().className("android.widget.ListView"));

  words.setAsVerticalList();

  for (String s : items) {
    Assert.assertNotNull("Could not find " + s,
        words.getChildByText(new UiSelector().className("android.widget.TextView"),
            s));
  }
}
```

(from Testing/UiAutomator/app/src/androidTest/java/com/commonsware/android/abf/uiautomator/ListTests.java)

testAdd()

The objective of the `testAdd()` method is to add a new word to the list, via the `EditText` widget in our action bar, then confirm that the new word was actually added to the list.

To do that, we:

- Retrieve the `EditText` by finding the widget whose text is "Word" (the hint of our `EditText`)
- Call `setText()` to fill in `snicklefritz` into the `EditText` widget, which `UiObject` accomplishes by actually typing in the value
- Call `pressEnter()` on the `UiDevice` to simulate pressing the Enter key of a keyboard, which will trigger our action listener in the test activity and will add the word to the list
- Create a `UiScrollable` for a `UiSelector` that finds the `ListView` in our activity
- Mark that `UiScrollable` as being a vertical list, where swipes up and down will expose the various children
- Try to find a `TextView` whose text is `snicklefritz` and assert that it was found

```
@Test
public void testAdd() throws UiObjectNotFoundException {
  UiObject add=device.findObject(new UiSelector().text("Word"));

  add.setText("snicklefritz");
  device.pressEnter();

  UiScrollable words=
      new UiScrollable(
                      new UiSelector().className("android.widget.ListView"));

  words.setAsVerticalList();

  Assert.assertNotNull("Could not find snicklefritz",
      words.getChildByText(new UiSelector().className("android.widget.TextView"),
          "snicklefritz"));
}
```

(from Testing/UiAutomator/app/src/androidTest/java/com/commonsware/android/abf/uiautomator/ListTests.java)

Cleaning Up

Our `ListTests` class also has a `tearDown()` method, invoked by JUnit after each test method courtesy of the `@After` annotation. Here, we press BACK twice, to return us to the main home screen from our activity, setting things back up for the next test method:

```
@After
public void tearDown() {
  device.pressBack();
  device.pressBack();
}
```

(from Testing/UiAutomator/app/src/androidTest/java/com/commonsware/android/abf/uiautomator/ListTests.java)

Running Your Tests

You run your UI Automator tests as you would any other instrumentation test:

- By running the run configuration that you set up for your tests in Android Studio
- By running commands like `gradle connectedCheck` at the command line
- Through integrations into your continuous integration server or similar build infrastructure

Finding Your Widgets

The key to finding your desired widgets stems in large part from the `text()` or `description()` methods on `UiSelector`. Of those two, the latter is more flexible, as it will use the `android:contentDescription` from any widget, while `text()` is limited to `TextView` and its subclasses.

However, this implies that your widgets have `android:contentDescription` defined. This is also important for accessibility, and therefore is a good idea regardless of its use with UI Automator.

For testing your own code, you can also find widgets via their resource IDs. `UiSelector` has `resourceId()` and `resourceIdMatches()` methods to configure the resource ID you want. As the `resourceIdMatches()` method name suggests, the resource ID here is a *string representation* of the resource name. It will be of the form `your.app.package:id/resource` (e.g., `com.commonsware.android.hotkey:id/editor`). However:

- Note that this requires API Level 18 or higher versions of the two JARs (`UI Automator.jar` and `android.jar`)
- Note that this requires running the tests on an API Level 18+ device or emulator
- Bear in mind that third party apps are welcome to rename their widgets when they wish, so your integration tests may break when third parties do so

Using the UI Automator Viewer

Identifying widgets can be a bit tricky with UI Automator. Identifying widgets *in other apps*, for your integration tests, would in theory be next to impossible. After all, while the Android Studio layout inspector and the older Hierarchy View tools can give you widget IDs, that only works with debuggable apps. *Your* app may be debuggable, but the app you are trying to integrate with probably is not.

Fortunately, we have the UI Automator Viewer. This tool basically walks the view hierarchy of whatever activity is in the foreground of a device (or emulator) and gives us access to whatever information is exposed by the accessibility APIs. Nowadays, this includes widget IDs, in addition to more traditional accessibility data like the text in a `TextView`, the `contentDescription` of an `ImageView`, and so on.

At the present time, the UI Automator Viewer is not integrated into Android Studio or the Android Device Monitor GUIs. Instead, you will have to launch it the old-fashioned way, by running the `uiautomatorviewer` command from the command line. This will map to a batch file or shell script in the `tools/` directory of your Android SDK installation.

When initially launched, the UI Automator Viewer does not look like much:

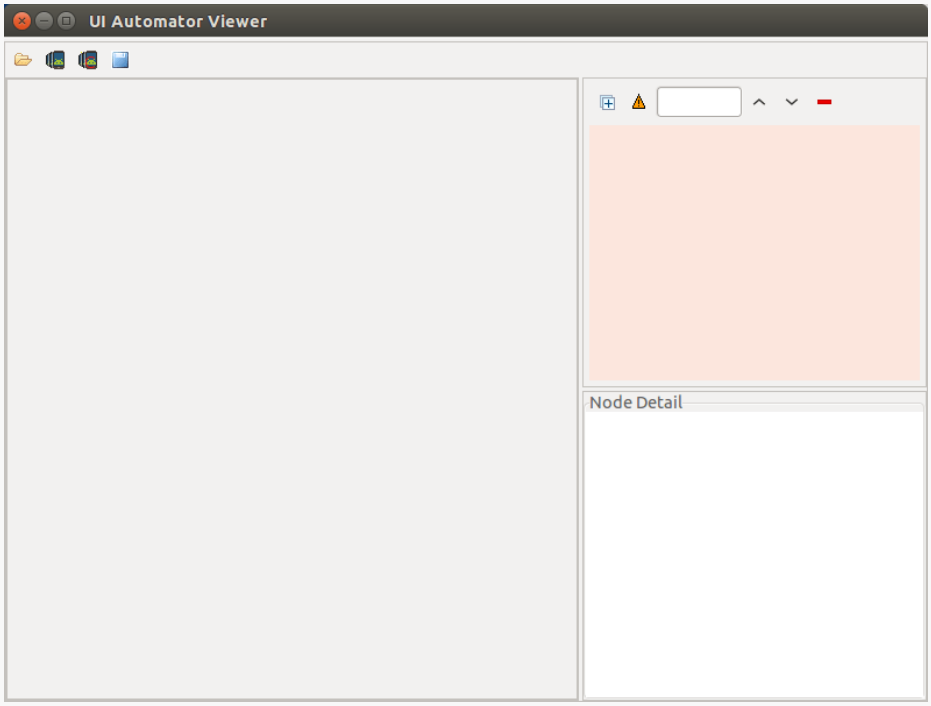

Figure 359: UI Automator Viewer, As Initially Launched

Given that you have a device or emulator ready, you can click the second icon from the left in the toolbar, to capture the view hierarchy of the foreground activity. This will give you:

- A screenshot of the foreground activity in the main area of the UI Automator Viewer screen
- The view hierarchy of that activity, in the upper-right corner of the UI Automator Viewer screen
- Properties of a node from the selected view, in the lower-right corner of the UI Automator Viewer screen

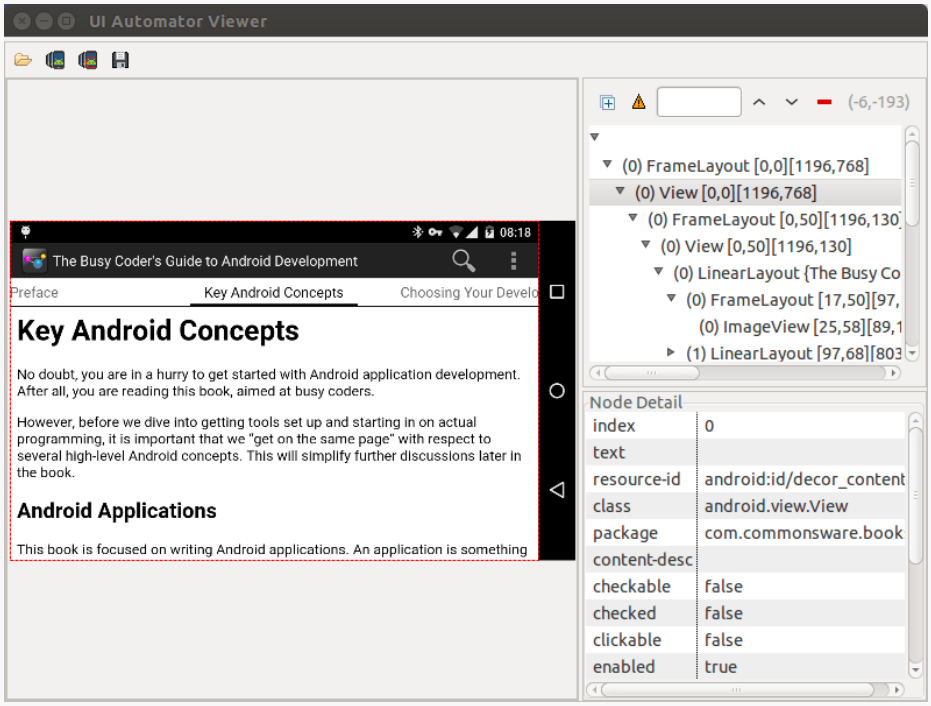

Figure 360: UI Automator Viewer, Showing View Hierarchy of This Book's Reader App

Clicking either on the preview or on the view hierarchy will change the selected view, which shows up with a red dashed outline on the preview. The properties ("Node Detail") pane will then update to show the properties of whatever is newly selected.

This is not only useful for identifying widgets for testing with UI Automator, but it can also be used to determine how some other developer pulled off some interesting UI approach. While simply examining a widget hierarchy is not going to uncover all the other developer's secrets, simply knowing what widgets were used, and some basic properties of those widgets, may give you some ideas for avenues of research.

Measuring Test Coverage

Test coverage is our way of determining whether or not we have adequately tested our code. Part of the work that has gone into the Android Gradle Plugin has been to make obtaining test coverage reports fairly easy, so ideally it is something that you can incorporate into your regular testing regimen.

In this chapter, we will explore the concept of test coverage in general, along with how to generate coverage reports for your Android instrumentation tests.

Prerequisites

Understanding this chapter requires that you have read the chapter on instrumentation testing with JUnit.

Who Tests the Testers?

We use tests to determine if our code works. More generally, we use tests as a way of quantifying the quality of our code. Code that fails the tests is of lower quality than is code that does not fail the tests.

Right?

Suppose we have some Java code that will result in divide-by-zero exception. We have two developers test that code. One developer writes tests and uncovers the exception. The other developer writes tests that bypasses the flawed code, and therefore does not uncover the exception. Here, the code quality is the same, but the *test quality* differs.

If the way we measure code quality is "does it pass the tests", measuring test coverage asks "do the tests adequately test the code?". In the preceding example, either:

- The second developer would have worse test coverage than the first developer, as the second developer clearly is not testing everything, or
- *Both* developers would have poor test coverage, and it just so happens that one stumbled upon the bug ("Even a blind squirrel finds a nut once in a while")

What you want is to have a test suite that has 100% practical coverage. The "practical" qualifier is because there are certain portions of our code that may be impractical to test, because they depend upon certain environmental factors that are different to arrange to happen on demand (e.g., `OutOfMemoryError`). There, the objective is to have as little code specifically dependent upon those factors, moving more of it into code that we can test without requiring those conditions.

Some Types of Test Coverage

Some developers that start in on test coverage think that test coverage is fairly simple to measure: did we run everything? The problem is that "run" has different meanings in different circumstances, and as a result measuring coverage can be done in different ways.

Statement Coverage

The basic approach to measuring test coverage is: did we execute every line of Java code? Clearly, if we never executed a line of code, we did not test that line and have no idea if that line works or not.

Branch Coverage

However, just because we execute a line does not mean that we have executed it under all conditions. Imagine a Java method like this:

```
void doSomething(boolean flag) {
  if (flag) {
    // do one thing
  }
  else {
    // do something else
```

```
  }
}
```

If this method were in our own Java code, we could determine whether we have tested both `true` and `false` cases by means of statement coverage. Either we executed the statements in both branches, or we did not.

However, suppose the method instead looked like this:

```
void doSomething(boolean flag) {
  if (flag) {
    // do one thing
  }

  // do something regardless of the flag value
}
```

Now, 100% statement coverage tells us that we executed the contents of the `if` block. However, it does *not* tell us if we have tested the case where `flag` is `false`, since no additional statements are executed for that case.

Branch coverage, therefore, measures whether our `if` and `switch` statements have covered all scenarios. We might have 100% statement coverage but below 100% branch coverage.

Loop Coverage

The coverage capability integrated into Android Studio offers statement and branch coverage. This does not mean that it includes *all* forms of coverage measurement.

Another common one is loop coverage. Imagine your typical Java `for` loop:

```
void doSomething(int count) {
  for (int i=0;i<count;i++) {
    // do something
  }
}
```

Statement coverage helps here, but only a little. 100% statement coverage would tell us that we executed the code inside the `for` loop. However, like branch coverage, it does not tell us if we are correctly handling the case where `count` is `0`, because we are not executing additional statements in that case.

Also, there are certain types of bugs that only show up if you execute the code inside the loop multiple times. Statement coverage cannot tell us if we tried `count` of `1` and a count greater than `1`, and so there may be some missed bugs.

Loop coverage is usually interpreted as testing three cases:

- Zero passes through the loop
- One pass through the loop
- More than one pass through the loop

Usually, the coverage tool does not know what the logical bounds are for the loop. In theory, there could be a bug that is only found if you execute the loop 349,320 times. However, finding that would require us to try testing every possible `count` value, and executing a couple of billion tests might take a while.

Coverage and Your Instrumentation Tests

The Android Gradle Plugin integrates support for Jacoco, a popular test coverage analyzer tool. Enabling it and measuring your test coverage is very simple.

First, make sure that you are using `0.5` or higher of the `com.android.support.test:rules` artifact, as coverage support was unavailable in some earlier versions.

Then, for the `debug` build type (and others if desired), enable test coverage via the `testCoverageEnabled = true` statement.

The `Testing/Coverage` sample project is a clone of the `Testing/JUnit4` project, with test coverage enabled in the `app` module's `build.gradle` file:

```
apply plugin: 'com.android.application'

dependencies {
    implementation "com.android.support:support-fragment:27.0.2"
    androidTestImplementation 'com.android.support.test:rules:1.0.1'
}

android {
    compileSdkVersion 27
    buildToolsVersion '27.0.3'

    defaultConfig {
        minSdkVersion 15
        targetSdkVersion 27
        testApplicationId "com.commonsware.android.gradle.hello.test"
        testInstrumentationRunner "android.support.test.runner.AndroidJUnitRunner"
```

```
    }

    buildTypes {
        debug {
            testCoverageEnabled = true
        }
    }
}
```

(from Testing/Coverage/app/build.gradle)

At least through Android Studio 2.1, you cannot generate a test coverage report through some simple toolbar button. You need to execute the `createDebugCoverageReport` Gradle task. You can do that from the command line, or you can do that from the Gradle tool, docked by default on the right side of Android Studio:

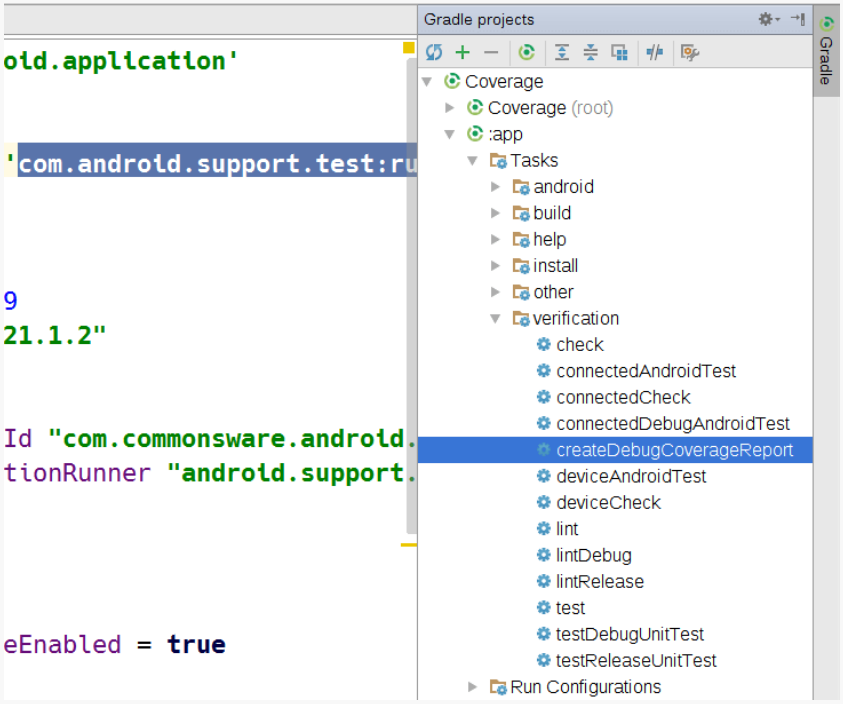

Figure 361: Android Studio Gradle Tool, Showing createDebugCoverageReport Task

Double-clicking a task in the Gradle tool executes that task, just as if you had run it from the command line. The `createDebugCoverageReport` runs your tests and builds a report based on the coverage logging that the build tools add when you have `testCoverageEnabled = true`.

Then, you can browse to the `build/reports/coverage/debug/` directory in your module (replacing `debug` with your build type, if you are using a different build type). That directory holds the HTML report generated by Jacoco of how your test coverage is:

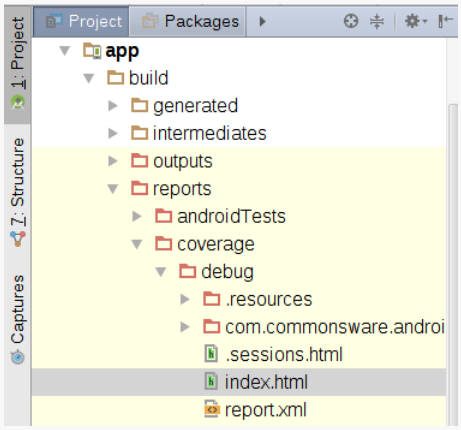

Figure 362: Android Studio, Showing Coverage Report Directory

By default, if you double-click on `index.html`, Android Studio will want to show you the HTML source code in an editor, which is less than useful here. Instead, right-click on it and choose "Open in Browser" to open it in your preferred Web browser:

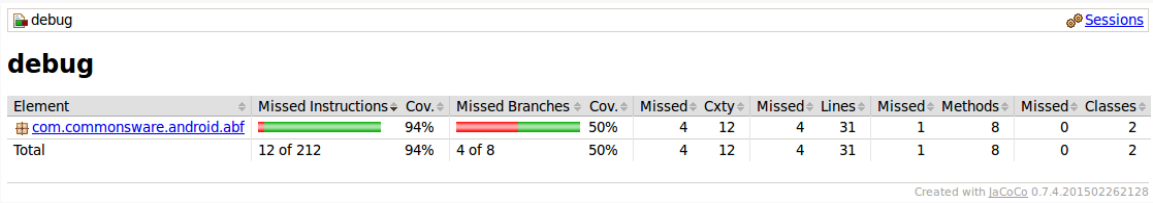

Figure 363: Jacoco Coverage Report, Top Level

Here, we see that we tested one Java package (`com.commonsware.android.abf`) and achieved 94% statement ("instruction") coverage and 50% branch coverage.

You can drill down into the report by clicking on a package to see how individual classes fared:

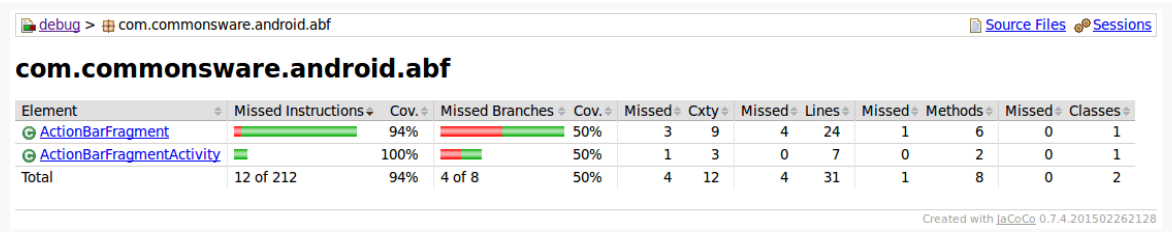

Figure 364: Jacoco Coverage Report, Package Level

Similarly, clicking on a class gives you details of individual methods and constructors:

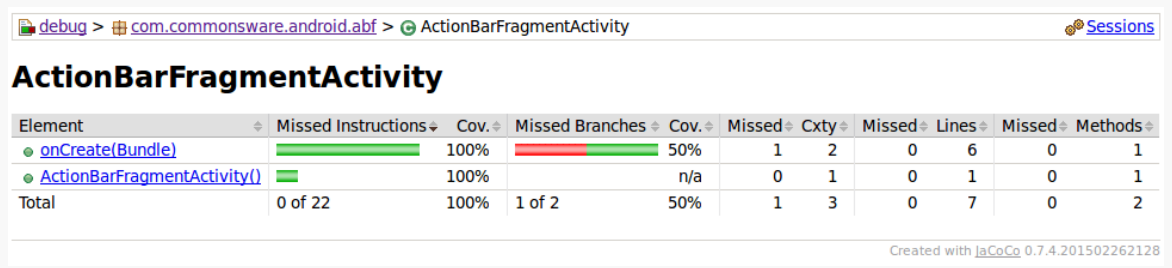

Figure 365: Jacoco Coverage Report, Class Level

Clicking on individual methods will show you highlighted source code of what was covered and what was missed:

Figure 366: Jacoco Coverage Report, Source Highlights

Here, the yellow line with the diamond marker indicates that we did not achieve full branch coverage. In this case, we have not handled a configuration change in the tests, so our fragment always needs to be created.

Unit Testing

Instrumentation testing — basically, all the approaches on testing covered so far in this book — is wonderful, but it has one key problem: it is **slow**.

The problem stems largely from the fact that we are running our Android tests in Android. Android emulators are not speedy, and neither are devices, compared with developer machines, continuous integration servers, and the like.

Unit testing, in Android terms, is taking a subset of our tests out of Android and onto our development machine OS itself, running them just as we would plain Java tests in non-Android Java development. On the plus side, we now have much more machine power to run our tests, including the possibility of running tests in parallel across multiple CPU cores. However, whatever we are running for our development OS probably is not Android, and so attempts to use Android from our tests are doomed to failure... unless we mock Android.

In this chapter, we will explore more of why we might want to set up unit tests, the basics of setting up unit testing for plain old Java objects (POJOs), and how to use Mockito and Robolectric to mock certain things, notably Android itself.

Prerequisites

This chapter assumes that you have read the preceding chapters on testing, particularly the one covering JUnit4.

Also, the examples in this chapter are based on the Retrofit example from the chapter on Internet access, so if you skipped the Retrofit material, you may wish to go back and review that section.

I Thought We Were Already Unit Testing?

If you used the testing techniques outlined previously in this chapter, you used JUnit, probably JUnit4. Given that JUnit has "unit" in the name, you might have thought that you were doing unit testing.

From the standpoint of standard testing terminology, you may very well have been doing unit testing.

However, in Android development, the phrase "unit testing" is reserved for outside-of-Android tests, running on a JVM on your development machine. Tests using JUnit that are run on Android itself are either "instrumentation tests" (if you are working with activities and related components directly) or "integration tests" (if you are using UIAutomator to exercise your app and other apps to see if they interoperate correctly).

Scenario: Clean Architecture

Robert Martin (a.k.a., "Uncle Bob"), in 2012, wrote a seminal blog post outlining what he refers to as "Clean Architecture". Others have posted their own variations on his original theme.

Usually, Clean Architecture is depicted as a set of concentric circles:

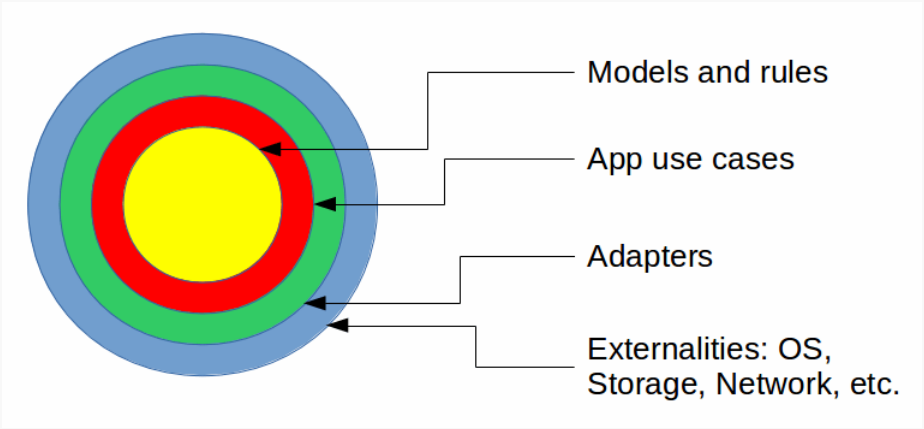

Figure 367: Clean Architecture

The basic rules are:

- The further in from the outside edge you go, the higher level the software becomes
- Nothing from an inner circle can depend upon something in an outer circle

The net of this, from an Android-and-testing standpoint, is that Clean Architecture results in a core set of Java objects that know nothing about Android. Typically, these are model objects and business rules (implemented as some mix of model object methods and separate rule objects). These core objects should know nothing about:

- Activity lifecycles
- Fragments or other UI implementation patterns
- Views or other forms of UI (e.g., Web content in a `WebView`)
- SQLite or any other particular storage engine
- Threads, including idiosyncrasies around the main application thread
- and so on

Even developers who do not adhere religiously to Clean Architecture often strive to have some core objects be "clean enough" and independent from anything specific to Android.

Since these objects have nothing specifically to do with Android, they should be testable outside of Android, even if in production you only intend to use them in Android apps. After all, if they do not need Android, why do you need the testing overhead of Android?

This is where unit testing comes into play, allowing you to set up a set of tests that do not require Android, because the objects being tested to not require Android.

Of course, this is not the only scenario where unit testing can be used. Many apps have some amount of utility code that is not tied too closely to Android. And, as we will see, even some code that has light ties to Android might be able to be tested through unit testing, courtesy of mocking frameworks.

Setting Up Unit Testing

There are three main steps for setting up unit testing: adding JUnit, toggling Android Studio to unit test mode, and creating the `test/` source set for holding your unit tests themselves.

The files shown in this section come from the UnitTest/POJO sample application. This is a clone of the HTTP/Retrofit example from the chapter on Internet access, where we retrieve the latest android-tagged Stack Overflow questions and display them in a ListView.

Adding the Test JUnit Dependency

Gradle, along with the Android Gradle Plugin, are set up to handle unit tests "out of the box". However, they still require you to provide a dependency on JUnit. Partially, that is because you may care about the specific version of JUnit that you use. Partially, that opens the door for possibly using other test engines beyond JUnit.

In previous chapters, we saw that instrumentation tests were handled using an androidTest/ source set and androidTestImplementation dependency statements. Similarly, unit testing is handled via a test/ source set and testImplementation dependency statements. So, to set up JUnit for unit testing, all you need is this in your module's build.gradle file:

```
apply plugin: 'com.android.application'

android {
    compileSdkVersion 27
    buildToolsVersion '27.0.3'

    defaultConfig {
        minSdkVersion 15
        targetSdkVersion 27
        testApplicationId "com.commonsware.android.unittest.tests"
        testInstrumentationRunner "android.support.test.runner.AndroidJUnitRunner"
    }
}

dependencies {
    implementation "com.android.support:support-fragment:27.0.2"
    implementation 'com.squareup.retrofit:retrofit:1.9.0'
    testImplementation 'junit:junit:4.12'
    androidTestImplementation 'com.android.support.test:rules:1.0.1'
}
```

(from UnitTest/POJO/app/build.gradle)

The version of JUnit will change over time, so the latest-and-greatest one may be newer than what you see above. Also, you may wind up with other testImplementation dependencies — we will see examples of this coming up later in this chapter.

Also note that new Android Studio projects, created through the new-project wizard, may already have this dependency.

You will also notice that this `build.gradle` file is set up to use instrumentation testing as well, with `androidTestImplementation`, `testApplicationId`, and so forth. That is not required for unit testing, but this project uses both testing approaches, to help compare and contrast the results.

Creating the Test Sourceset

New Android Studio projects, created through the new-project wizard, automatically get a `test/` source set added alongside `main/` and `androidTest/`. That `test/` source set will already have an `ExampleUnitTest` class added to the Java package associated with the app.

If you have an existing Android Studio project, though, you will need to set up the `test/` directory, the `test/java/` directory, and add a Java package to that `test/java/` directory yourself. Note that this will be easier if you switch Android Studio to unit test mode. While Android Studio is in instrumentation test mode, it will not recognize a `test/java/` directory as being a viable location for Java source code. That means you will not have a context menu option to add a Java package, forcing you to create each directory yourself, one at a time (e.g., `test/java/com/`, then `test/java/com/commonsware/`, then...). With Android Studio in unit test mode, `test/java/` will be a normal Java source directory, and you can add new Java packages to it from the context menu (right-click over `java/`) as you would in your `main` source set.

Either way, in the end, you should have a `test/` source set as a peer of your `main/` and `androidTest/` source sets:

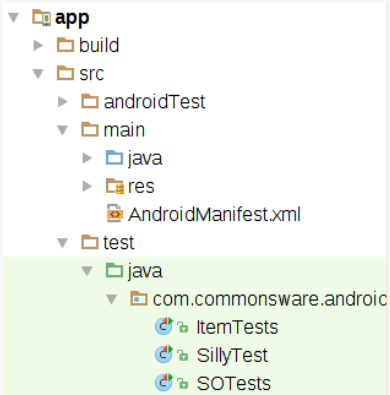

Figure 368: Project View, Showing main/, androidTest/, and test/ Sourcesets

However, only the `main/` source set and your chosen test artifact's source set will show up with normal-looking Java directories. So, for example, with unit testing selected as the test artifact, the source code in `androidTest/` is not really recognized as being Java code that is part of the project:

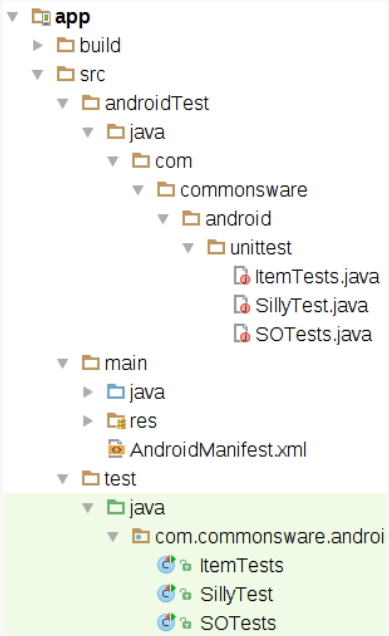

Figure 369: Project View, Showing Unrecognized androidTest/ Java Code

Writing POJO Unit Tests

That setup is all that you need in order to start writing unit tests for your plain old Java objects (POJOs), utility code, or other things that do not depend on Android.

Adding the Test Package

If you had to create the `test/` source set, you will also need to create the `test/java/` directory, and in there create a Java package for your test code.

In Android Studio, this will be much simpler if Android Studio is in unit test mode (versus instrumentation test mode), as then you will have a New > Package option in the context menu, if you right-click over the `java/` directory.

As with other JUnit testing, your choice of package dictates what you can and cannot access of classes and objects being tested:

Test Package	Public	Package-Private	Private
same as class being tested	yes	yes	no
different than class being tested	yes	no	no

In the sample project, the test code is in the same Java package as is the `main` application code, so tests can access `public` and package-private fields, methods, and the like.

Writing a Test Case

We can have a `SillyTest` test case, just as in the chapter on JUnit4. However, we do not need the `@RunWith` annotation on the class:

```
package com.commonsware.android.unittest;

import junit.framework.Assert;
import org.junit.After;
import org.junit.AfterClass;
import org.junit.Before;
import org.junit.BeforeClass;
import org.junit.Test;

public class SillyTest {
  @BeforeClass
  static public void doThisFirstOnlyOnce() {
    // do initialization here, run once for all SillyTest tests
  }

  @Before
  public void doThisFirst() {
    // do initialization here, run on every test method
  }

  @After
  public void doThisLast() {
    // do termination here, run on every test method
  }

  @AfterClass
  static public void doThisLastOnlyOnce() {
    // do termination here, run once for all SillyTest tests
  }

  @Test
  public void thisIsReallySilly() {
```

```
    Assert.assertEquals("bit got flipped by cosmic rays", 1, 1);
  }
}
```

(from UnitTest/POJO/app/src/test/java/com/commonsware/android/unittest/SillyTest.java)

If you created your project through the Android Studio new-project wizard, and it already had a `test/` source set for you, it would have created a similarly-silly `ExampleUnitTest` test case for you:

```
public class ExampleUnitTest {
  @Test
  public void addition_isCorrect() throws Exception {
    assertEquals(4, 2+2);
  }
}
```

Of course, you can start writing your own test cases that are somewhat less silly. Here, we have a test case that confirms the `toString()` behavior of the `Item` class:

```
package com.commonsware.android.unittest;

import junit.framework.Assert;
import org.junit.Test;

public class ItemTests {
  private static final String TITLE="this is a title";
  private static final String URL="https://commonsware.com";

  @Test
  public void iCanHazString() {
    Item item=new Item();

    item.title=TITLE;
    item.link=URL;

    Assert.assertEquals(TITLE, item.toString());
  }
}
```

(from UnitTest/POJO/app/src/test/java/com/commonsware/android/unittest/ItemTests.java)

Testing loading the questions gets a bit tricky, as our `StackOverflowInterface` is set up for asynchronous operation. When we call `questions()` to get the questions, we get control back immediately, and we need to wait for the background thread to

deliver our results. There are a few patterns for handling this. This particular test case uses a `CountDownLatch`:

```
package com.commonsware.android.unittest;

import junit.framework.Assert;
import org.junit.Before;
import org.junit.Test;
import java.util.concurrent.CountDownLatch;
import retrofit.Callback;
import retrofit.RestAdapter;
import retrofit.RetrofitError;
import retrofit.client.Response;

public class SOTests {
  private CountDownLatch responseLatch;
  private SOQuestions questions;

  @Before
  public void setUp() {
    responseLatch=new CountDownLatch(1);
  }

  @Test(timeout=30000)
  public void fetchQuestions() throws InterruptedException {
    RestAdapter restAdapter=
      new RestAdapter.Builder()
        .setEndpoint("https://api.stackexchange.com")
        .build();
    StackOverflowInterface so=
      restAdapter.create(StackOverflowInterface.class);

    so.questions("android", new Callback<SOQuestions>() {
      @Override
      public void success(SOQuestions soQuestions,
                          Response response) {
        questions=soQuestions;
        responseLatch.countDown();
      }

      @Override
      public void failure(RetrofitError error) {
        responseLatch.countDown();
      }
    });

    responseLatch.await();
```

```
    Assert.assertNotNull(questions);
    Assert.assertEquals(30, questions.items.size());

    for (Item item : questions.items) {
      Assert.assertNotNull(item.title);
      Assert.assertNotNull(item.link);
    }
  }
}
```

(from UnitTest/POJO/app/src/test/java/com/commonsware/android/unittest/SOTests.java)

When the test is `setUp()`, we initialize the `CountDownLatch`, to require one `countDown()` call before the latch is considered to be released.

In our `fetchQuestions()` test method, we go through the same sort of code that `QuestionsFragment` does, creating our `RestAdapter` and `StackOverflowInterface`. When we call `questions()`, we supply an anonymous inner class instance of the `Callback`. In both `success()` and `failure()`, we `countDown()` our `CountDownLatch`. If the call succeeded, we also hold onto the `SOQuestions` model object.

Immediately after calling `fetchQuestions()`, we `await()` on the `CountDownLatch`. The `Callback` will be called on a background thread, so the `await()` call means that we are blocking until such time as we are called with `success()` or `failure()`. Also, as a fail-safe measure, the `@Test` annotation for this test method is configured as `@Test(timeout=30000)`, meaning that if we do not get a response in 30 seconds, we fail the test.

Once we get control after the `success()` or `failure()` call, we confirm and see if we got our 30 questions and that each `Item` seems to be filled out.

Running Unit Tests

Once you have one or more unit tests, you can start thinking about running them and seeing if they work. Running unit tests does not require a device or emulator, as these tests are running on your development machine's OS directly (in a standard Java VM), not on Android.

From Android Studio

From the project tree, right-clicking over a class or a package will give you a context menu option to run the tests in that class or package:

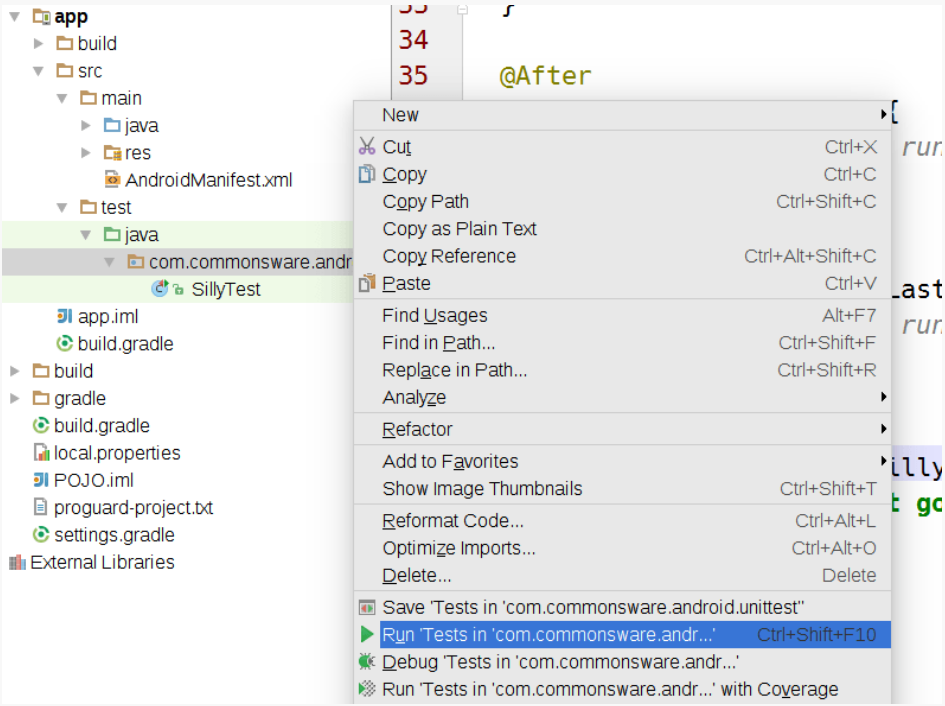

Figure 370: Run Tests Context Menu Item for Test Package

You can even right-click over the name of a method in your test class and have an option for running just that method:

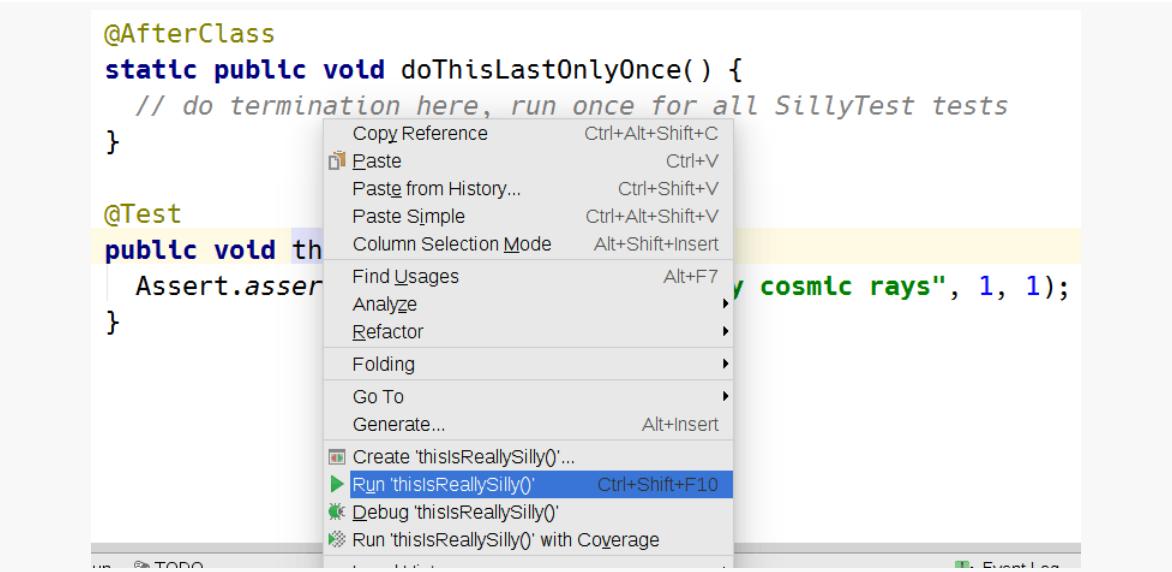

Figure 371: Run Test Context Menu Item for Test Method

While convenient, this will clutter up your run configurations drop-down:

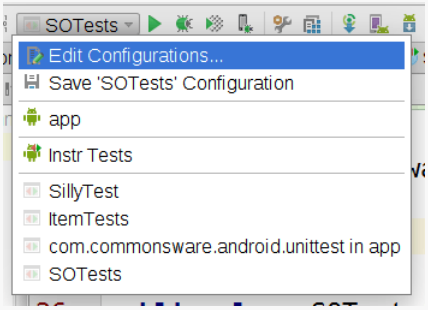

Figure 372: Run Configurations, After Running Unit Tests

The entries with the faded-out icons represent run configurations that were added dynamically based on your right-click test runs. The most recent of those becomes the current run configuration (shown here as "SOTests"), and you have an option to "save" that and make it a regular run configuration.

If you try running the various unit tests for the sample app, `SillyTest` and `ItemTests` work, but `SOTests` does not. Apparently, Retrofit depends too much on Android, since the same test code succeeds when run as an instrumentation test. We will discuss how to deal with that problem later in this chapter.

From the Command Line

The `test` task in Gradle runs all of your unit tests for the module in which you run that task. The command line output will show you a summary of the results, in this case demonstrating the failure of `SOTests`:

```
$ gradle test
:app:preBuild UP-TO-DATE
:app:preDebugBuild UP-TO-DATE
:app:checkDebugManifest
:app:prepareDebugDependencies
:app:compileDebugAidl
:app:compileDebugRenderscript
:app:generateDebugBuildConfig
:app:generateDebugAssets UP-TO-DATE
:app:mergeDebugAssets
:app:generateDebugResValues
:app:generateDebugResources
:app:mergeDebugResources
:app:processDebugManifest
:app:processDebugResources
:app:generateDebugSources
:app:compileDebugJavaWithJavac
:app:preDebugUnitTestBuild UP-TO-DATE
:app:prepareDebugUnitTestDependencies
:app:compileDebugUnitTestJavaWithJavac
:app:processDebugJavaRes UP-TO-DATE
:app:processDebugUnitTestJavaRes UP-TO-DATE
:app:compileDebugUnitTestSources
:app:mockableAndroidJar
:app:assembleDebugUnitTest
:app:testDebugUnitTest

com.commonsware.android.unittest.SOTests > fetchQuestions FAILED
    junit.framework.AssertionFailedError at SOTests.java:60

3 tests completed, 1 failed
:app:testDebugUnitTest FAILED

FAILURE: Build failed with an exception.

* What went wrong:
Execution failed for task ':app:testDebugUnitTest'.
> There were failing tests. See the report at: file:///home/mmurphy/stuff/CommonsWare/
books/Omnibus/samples/UnitTest/POJO/app/build/reports/tests/debug/index.html

* Try:
```

```
Run with --stacktrace option to get the stack trace. Run with --info or --debug
option to get more log output.

BUILD FAILED

Total time: 14.188 secs
```

We see that three tests completed, but one (`SOTests`) failed.

In `build/output/reports/tests/` will be HTML reports showing the results of the tests:

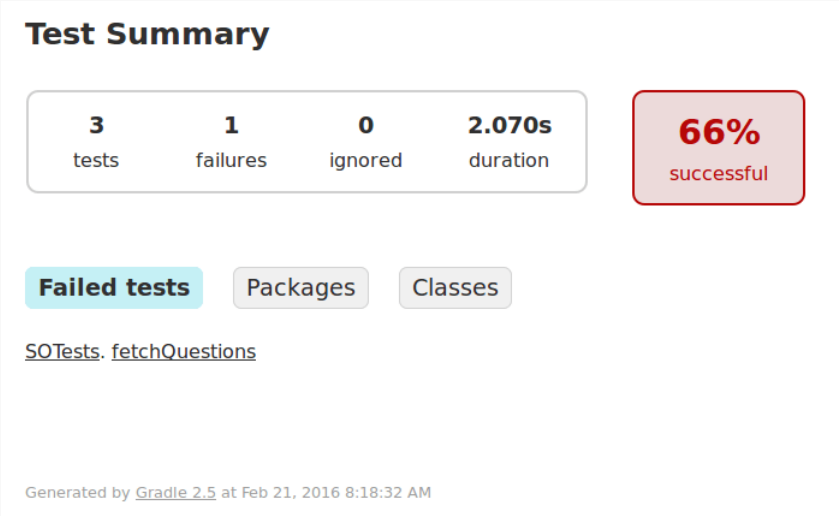

Figure 373: Unit Test Report, Summary

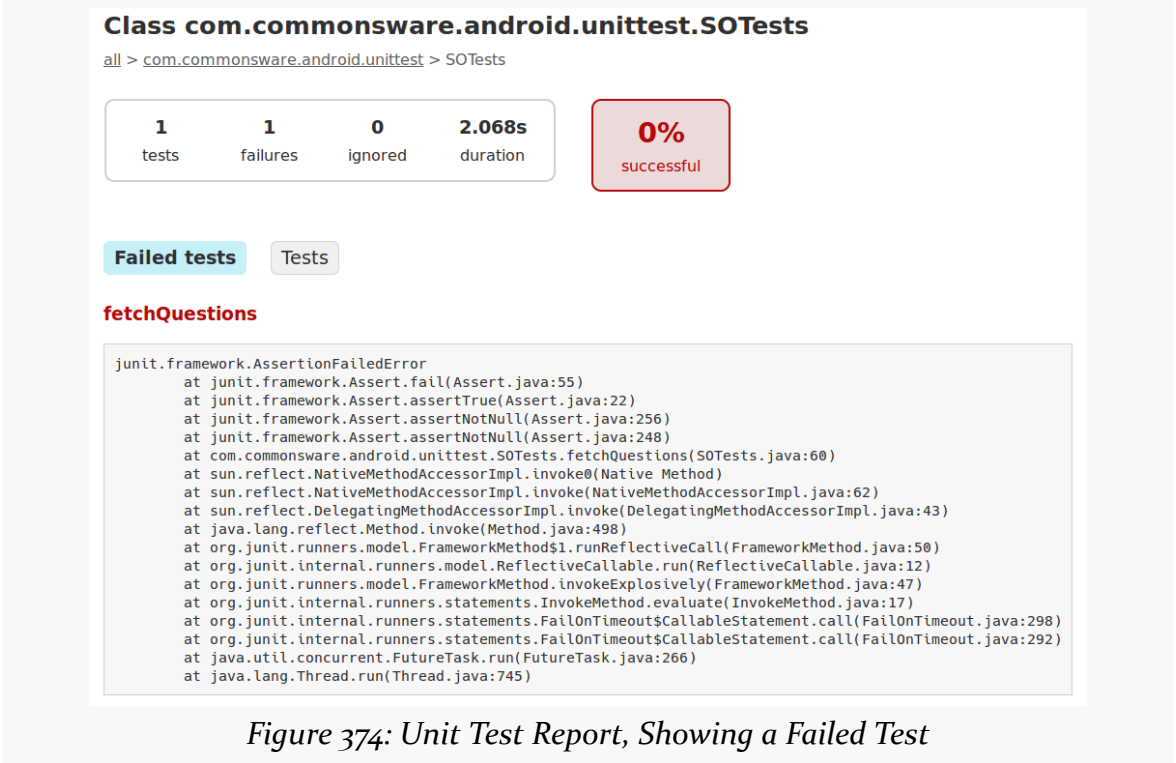

Figure 374: Unit Test Report, Showing a Failed Test

There are XML files in `build/output/test-results/` that contain the same basic information. These are mostly designed for use by tools, such as perhaps a CI server.

Mocking Android

Unit tests that go beyond stuff in common between the JVM and Android are going to have problems, such as the Retrofit example described above. For pure POJOs, this will not be a major limitation. But you might have other code that has little real connection to Android that you would like to test using unit testing, for the faster speed. However, unit testing is fairly unforgiving: "little real connection" is not "no connection", and so your tests will fail.

Hence, to fix unit testing, we need to mock Android.

Why Are We Being Mean to Android?

In this case, "mock" is not a synonym for "taunt".

Instead, "mock" refers to creating mock objects. Wikipedia describes this as:

> In object-oriented programming, mock objects are simulated objects that mimic the behavior of real objects in controlled ways. A programmer typically creates a mock object to test the behavior of some other object, in much the same way that a car designer uses a crash test dummy to simulate the dynamic behavior of a human in vehicle impacts.

(from a February 2016 edition of the page)

For example, in many places in Android, we need a `Context`. Sometimes, we do not really use the `Context` at all ourselves — it is input to some lower layer of code, and therefore we accept it as input to our layer and pass it along. In those cases, perhaps a mock `Context` will suffice to allow our tests to run. Or, perhaps endowing the mock `Context` with some limited amount of test-defined functionality will suffice to allow our tests to run.

There are many mock frameworks for programming environments, including a few for Java, and some of those Java ones are Android-friendly. This section will look at one of those, Mockito. This section will also look at Robolectric, a framework specifically for mocking the Android SDK.

Mockito

Mockito is a general-purpose mocking library for Java that is officially supported by the Android tools team for use with Android unit testing. While there are other mocking libraries for Java (e.g., jMock, EasyMock), you may wish to start with Mockito given its official support status.

Why Mockito?

The idea behind any Java mocking library is to be able to create objects that, from a compilation standpoint, behave as do the real objects, but have test-controlled responses to methods (a.k.a., "stubs").

The quintessential Java example is mocking a `List`:

```
List fakeList=mock(List.class);

when(fakeList.get(0)).thenReturn(1337);
```

Here, we use an imported `static` `mock()` method to create a mock implementation of the `List` interface. `when()` captures a particular invocation that we wish to stub

out (in this case, getting the oth item in the list), and `thenReturn()` indicates what the return value should be for that invocation (in this case, `1337`). Later on, we can test our behavior:

```
Assert.assertEquals(1337, fakeList.get(0)); // succeeds
Assert.assertEquals(1337, fakeList.get(1)); // fails, as get(1) returns null
```

Since we taught the mock how to respond to `get(0)`, it returns `1337`. Anything else we try doing with the mock will result in some default behavior; in this case, calling `get()` for any other index will return `null`, since we have not defined values for any other indexes.

For limited tests like this, we are not really testing much in the way of actual app functionality. If anything, we are testing that Mockito is capable of mocking things. However, suppose instead that we did this:

```
OurClass sumthin=new OurClass();

Assert.assertEquals(1787569, sumthin.squareTheFirst(fakeList));
```

Here, we have a `squareTheFirst()` method implemented on some class of ours `OurClass`. As it turns out, the implementation of `squareTheFirst()` is to grab the oth element out of the supplied `List` and return the square of that integer value. Now we are testing actual application logic, confirming that our square is being computed properly.

Of course, in this case, it would be just as easy to create an `ArrayList`, rather than mess with a mock. However, there are plenty of cases where it would be too much work to create an instance of the class, including cases where it is nearly impossible. For example, we cannot create our own instances of system services, like `AlarmManager` or `NotificationManager`. If we want to test code that works with those, we are far better served using a mocking library like Mockito.

Setting Up Mockito

The `UnitTest/Mockito` sample application is based on the `POJO` one from earlier in the chapter. However, this version adds Mockito, specifically to help us play around with a mock version of Retrofit.

The Android tools team seems to be endorsing Mockito 1.x, as at the present time (February 2016), Mockito 2.0 is still in beta. Adding Mockito, therefore, is a matter of

adding a `testImplementation` statement to pull in an appropriate version of `mockito-core`:

```
dependencies {
    implementation "com.android.support:support-fragment:27.0.2"
    implementation 'com.squareup.retrofit:retrofit:1.9.0'
    testImplementation 'junit:junit:4.12'
    testImplementation 'org.mockito:mockito-core:2.10.0'
    androidTestImplementation 'com.android.support.test:rules:1.0.1'
}
```

(from UnitTest/Mockito/app/build.gradle)

Using Mockito in Unit Tests

Let's now use Mockito to create an `SOTests` that works, albeit using a fake Retrofit.

To use Mockito in a JUnit4 test class, you need to add the `@RunWith(MockitoJUnitRunner.class)` annotation to the class, to have the class run using a dedicated JUnit4 test runner that is Mockito-enabled. So, `SOTests` needs that annotation:

```
@RunWith(MockitoJUnitRunner.class)
public class SOTests {
```

(from UnitTest/Mockito/app/src/test/java/com/commonsware/android/unittest/SOTests.java)

We want a mock `StackOverflowInterface` object that we can use to call our `questions()` method and retrieve mock questions. There are two main ways in Mockito to create mock objects:

- the `mock()` method cited earlier
- the `@Mock` annotation

`SOTests` applies the latter, so one of the fields in the test class is a `@Mock` of `StackOverflowInterface`:

```
@RunWith(MockitoJUnitRunner.class)
public class SOTests {
  private CountDownLatch responseLatch;
  private SOQuestions questions;
  @Mock StackOverflowInterface mockSO;
```

(from UnitTest/Mockito/app/src/test/java/com/commonsware/android/unittest/SOTests.java)

We then need to teach our mock `StackOverflowInterface` how to return questions as needed.

If we were using Retrofit's synchronous API, the `questions()` method on `StackOverflowInterface` would return the `SOQuestions` object representing the results of our REST API call. In that case, mocking `StackOverflowInterface` could be (comparatively) simple, something like:

```
SOQuestions fakeQuestions=new SOQuestions();

fakeQuestions.items=new ArrayList<Item>();

Item fakeItem=new Item();

fakeItem.link="https://commonsware.com";
fakeItem.title="How Do I Fake It to Make It?";
fakeQuestions.items.add(fakeItem);

when(mockSO.questions()).thenReturn(fakeQuestions);
```

Here, we build up an `SOQuestions` instance containing a single `Item`, and we teach the `mockSO` object to return that in response to a call to `questions()`.

However, we are using Retrofit's asynchronous API, where we supply a `Callback` as a parameter. The `questions()` method is declared as `void`, so it does not return a response, and we will eventually be called with `success()` on our `Callback`.

We can mock that with Mockito, but it is more complicated:

```
    doAnswer(new Answer() {
      @Override
      public Object answer(InvocationOnMock invocation)
        throws Throwable {
        SOQuestions fakeQuestions=new SOQuestions();

        fakeQuestions.items=new ArrayList<Item>();

        Item fakeItem=new Item();

        fakeItem.link="https://commonsware.com";
        fakeItem.title="How Do I Fake It to Make It?";
        fakeQuestions.items.add(fakeItem);

        Callback<SOQuestions> realCB=
          (Callback<SOQuestions>)invocation.getArguments()[1];
```

```
      realCB.success(fakeQuestions, null);

      return(null);
    }
  }).when(mockSO).questions(eq("android"), any(Callback.class));
```

(from UnitTest/Mockito/app/src/test/java/com/commonsware/android/unittest/SOTests.java)

Let's trim this back to the essence of what we are doing:

```
doAnswer(...).when(mockSO).questions(...)
```

The `doAnswer()` flow is a way of handling `void` methods, as `thenReturn()` does not work, since a `void` method does not return anything. `doAnswer()` is where we do the "work" that the mock needs to do, in this case to call our `Callback`, as we will see shortly.

Chaining `questions()` onto the result of `when()` is another way of indicating a call that we are stubbing. However, in this case, our parameters are not simple primitives, like the `0` in `get(0)` from the `List` example depicted earlier in this section. We can provide information to `questions()` to indicate *which* `questions()` calls will get the answer provided by `doAnswer()`.

```
doAnswer(...).when(mockSO).questions(eq("android"), any(Callback.class))
```

The real `questions()` method takes a `String` representing the Stack Overflow tag of interest, plus the `Callback`. The particular invocation of `questions()` that we are stubbing will be used when `questions()` is called on our mock `StackOverflowInterface`, where the first parameter equals (`eq()`) `"android"`, and where the second parameter is `any()` instance of `Callback.class`. In principle, we could provide other stubs for other tags (e.g., `questions(eq("ios"), any(Callback.class))`), but that is beyond the scope of what we are doing here.

The value passed into `doAnswer()` is an anonymous inner class implementation of `Answer`. That object's `answer()` method will be called when our mock is called with a matching `questions()` call. It is our job, in `answer()`, to do whatever the mock needs to do to satisfy our tests.

Most of what is here builds up the same fake `SOQuestions` object as illustrated earlier. To actually pass that to the `Callback`, though, we need to:

- Get the `Callback` object in question, by calling `getArguments()` on the supplied `InvocationOnMock` object (which collects all the parameters passed into `questions()`) and gets the second entry from that array of objects
- Casts that to the correct type
- Calls `success()`, passing in the fake `SOQuestions`, plus a `null` value for the Retrofit `Response` object, as we are not using that

At that point, we can run our test, adjusting it to expect one `Item` instead of 30 as we were originally expecting:

```
    mockSO.questions("android", new Callback<SOQuestions>() {
      @Override
      public void success(SOQuestions soQuestions,
                          Response response) {
        questions=soQuestions;
        responseLatch.countDown();
      }

      @Override
      public void failure(RetrofitError error) {
        responseLatch.countDown();
      }
    });

    responseLatch.await();

    Assert.assertNotNull(questions);
    Assert.assertEquals(1, questions.items.size());

    for (Item item : questions.items) {
      Assert.assertNotNull(item.title);
      Assert.assertNotNull(item.link);
    }
```

(from UnitTest/Mockito/app/src/test/java/com/commonsware/android/unittest/SOTests.java)

In this case, everything should be happening on the same thread, and so it is likely that the `CountDownLatch` is superfluous. However, it does not cause us any particular harm here, and it keeps the code more closely aligned with the implementation in the instrumentation tests.

The whole test class, therefore, looks like this:

```
package com.commonsware.android.unittest;
```

```
import junit.framework.Assert;
import org.junit.Before;
import org.junit.Test;
import org.junit.runner.RunWith;
import org.mockito.Mock;
import org.mockito.invocation.InvocationOnMock;
import org.mockito.runners.MockitoJUnitRunner;
import org.mockito.stubbing.Answer;
import java.util.ArrayList;
import java.util.concurrent.CountDownLatch;
import retrofit.Callback;
import retrofit.RetrofitError;
import retrofit.client.Response;
import static org.mockito.Matchers.any;
import static org.mockito.Matchers.eq;
import static org.mockito.Mockito.doAnswer;

@RunWith(MockitoJUnitRunner.class)
public class SOTests {
  private CountDownLatch responseLatch;
  private SOQuestions questions;
  @Mock StackOverflowInterface mockSO;

  @Before
  public void setUp() {
    responseLatch=new CountDownLatch(1);
  }

  @Test(timeout=30000)
  public void fetchQuestions() throws InterruptedException {
    doAnswer(new Answer() {
      @Override
      public Object answer(InvocationOnMock invocation)
        throws Throwable {
        SOQuestions fakeQuestions=new SOQuestions();

        fakeQuestions.items=new ArrayList<Item>();

        Item fakeItem=new Item();

        fakeItem.link="https://commonsware.com";
        fakeItem.title="How Do I Fake It to Make It?";
        fakeQuestions.items.add(fakeItem);

        Callback<SOQuestions> realCB=
          (Callback<SOQuestions>)invocation.getArguments()[1];

        realCB.success(fakeQuestions, null);
```

```
      return(null);
    }
  }).when(mockSO).questions(eq("android"), any(Callback.class));

  mockSO.questions("android", new Callback<SOQuestions>() {
    @Override
    public void success(SOQuestions soQuestions,
                        Response response) {
      questions=soQuestions;
      responseLatch.countDown();
    }

    @Override
    public void failure(RetrofitError error) {
      responseLatch.countDown();
    }
  });

  responseLatch.await();

  Assert.assertNotNull(questions);
  Assert.assertEquals(1, questions.items.size());

  for (Item item : questions.items) {
    Assert.assertNotNull(item.title);
    Assert.assertNotNull(item.link);
  }
 }
}
```

(from UnitTest/Mockito/app/src/test/java/com/commonsware/android/unittest/SOTests.java)

If you run the `fetchQuestions()` test, it works. Of course, it is not really testing anything other than Mockito itself. In this particular app, the only thing we are using Retrofit for is to obtain a list of model objects to put in an `ArrayAdapter` to display in a `ListView`. Mockito cannot readily help us test whether our `ArrayAdapter` is inflating layouts properly, or whether `ListView` is using the `ArrayAdapter` properly. At best, we would wind up creating massive mocks that, once again, mostly just have us testing whether our mocks work, not our actual business logic.

This is not to say that Mockito is useless, but rather that its utility is for lightly extending the scope of what we can test of our POJOs in unit testing.

Mockito is a fairly large and complex library. There are multiple books available covering Mockito, should you need more than the project documentation and similar online sources. Just remember that Mockito is for general Java development and is not Android-specific.

Robolectric

Mockito mocks anything you want, so long as you are the one doing the mocking.

Robolectric mocks a part of the Android SDK for you. In particular, it mocks the setup and teardown of activities and services, so you can confirm that they are initialized properly through unit tests, instead of instrumentation tests. Robolectric also supports a limited amount of user input testing — mostly limited to click events — so you can determine whether or not your activity is reacting as expected.

On the one hand, Robolectric lets you set up some Android-specific unit tests "out of the box". On the other hand, the depth and breadth of its mocking is fairly limited, which will steer more of your tests back to instrumentation testing, where you have a full Android SDK at your disposal.

The `UnitTest/Robolectric` sample application is based on the one shown in the chapter on JUnit4, where we have 25 Latin words that we are showing in a list, and we want to test that the activity is coming up as expected.

Setting up Robolectric

You will need to add a `testImplementation` directive to your `build.gradle` file to pull in Robolectric, plus a `testOptions` closure in the `android` closure, advertising that you want resources to be available to you while testing:

```
apply plugin: 'com.android.application'

dependencies {
    implementation "com.android.support:support-fragment:27.0.2"
    testImplementation 'junit:junit:4.12'
    testImplementation "org.robolectric:robolectric:3.7.1"
    androidTestImplementation 'com.android.support.test:rules:1.0.1'
}

android {
    compileSdkVersion 27
    buildToolsVersion '27.0.3'

    defaultConfig {
        minSdkVersion 15
        targetSdkVersion 27
```

```
        testApplicationId "com.commonsware.android.gradle.hello.robolectric"
        testInstrumentationRunner "android.support.test.runner.AndroidJUnitRunner"
    }

    testOptions {
        unitTests {
            includeAndroidResources = true
        }
    }
}
```

(from UnitTest/Robolectric/app/build.gradle)

Choosing an API Level

A key decision that you will need to make, before writing any tests, is what API level you want Robolectric to mock. Robolectric does not have mocks for all API levels, as creating their roster of mocks takes work.

Unfortunately, the roster of supported API levels does not appear to be documented.

The Roboletric SdkConfig class class is the closest that we have to documentation, as it has a `static` block that sets up the supported SDKs. The following is from Robolectric 3.7.1:

```
private static final Map<Integer, SdkVersion> SUPPORTED_APIS =
Collections.unmodifiableMap(new HashMap<Integer, SdkVersion>() {
  {
    addSdk(Build.VERSION_CODES.JELLY_BEAN, "4.1.2_r1", "r1", "REL");
    addSdk(Build.VERSION_CODES.JELLY_BEAN_MR1, "4.2.2_r1.2", "r1", "REL");
    addSdk(Build.VERSION_CODES.JELLY_BEAN_MR2, "4.3_r2", "r1", "REL");
    addSdk(Build.VERSION_CODES.KITKAT, "4.4_r1", "r2", "REL");
    addSdk(Build.VERSION_CODES.LOLLIPOP, "5.0.2_r3", "r0", "REL");
    addSdk(Build.VERSION_CODES.LOLLIPOP_MR1, "5.1.1_r9", "r2", "REL");
    addSdk(Build.VERSION_CODES.M, "6.0.1_r3", "r1", "REL");
    addSdk(Build.VERSION_CODES.N, "7.0.0_r1", "r1", "REL");
    addSdk(Build.VERSION_CODES.N_MR1, "7.1.0_r7", "r1", "REL");
    addSdk(Build.VERSION_CODES.O, "8.0.0_r4", "r1", "REL");
    addSdk(Build.VERSION_CODES.O_MR1, "8.1.0", "r4402310", "OMR1");
  }

  private void addSdk(int sdkVersion, String androidVersion, String
frameworkSdkBuildVersion,
      String codeName) {
      put(sdkVersion, new SdkVersion(androidVersion, frameworkSdkBuildVersion,
codeName));
```

```
  }
});
```

This translates to support for API Level 16-19 and 21-27.

You will need to choose a suitable API level for your use. By default, Robolectric will use your `targetSdkVersion`, which may or may not be one of the supported API levels. You will need to know what Robolectric API level to use when you start setting up your tests.

Writing Robolectric Tests

At this point, you can start writing tests that use Robolectric. As with the Mockito tests and other unit tests, these will go in your `test/` source set.

The sample project has a `DemoActivityTest` that, in theory, would mimic the `DemoActivityTest` from the instrumentation tests in the `androidTest/` source set:

```
package com.commonsware.android.abf.test;

import android.widget.ListView;
import com.commonsware.android.abf.ActionBarFragmentActivity;
import com.commonsware.android.abf.BuildConfig;
import junit.framework.Assert;
import org.junit.Before;
import org.junit.Test;
import org.junit.runner.RunWith;
import org.robolectric.Robolectric;
import org.robolectric.RobolectricTestRunner;
import org.robolectric.annotation.Config;
import static android.os.Build.VERSION_CODES.JELLY_BEAN;

@RunWith(RobolectricTestRunner.class)
@Config(sdk=JELLY_BEAN)
public class DemoActivityTest {
  private ListView list=null;

  @Before
  public void setUp() throws Exception {
    ActionBarFragmentActivity activity=
      Robolectric.setupActivity(ActionBarFragmentActivity.class);

    list=activity.findViewById(android.R.id.list);
  }
```

```
  @Test
  public void listCount() {
    Assert.assertEquals(25, list.getAdapter().getCount());
  }
}
```

(from UnitTest/Robolectric/app/src/test/java/com/commonsware/android/abf/test/DemoActivityTest.java)

Your test case classes need two annotations. One is `@RunWith(RobolectricTestRunner.class)`, to tell the unit test system to use Robolectric's test runner rather than the stock JUnit one. If you *also* plan on using Mockito, since you cannot use two test runners, use the Robolectric one and add `MockitoAnnotations.initMocks(this);` to a `@Before` method of your test case, to initialize Mockito.

You can optionally include a `@Config` annotation, to configure Robolectric behavior. The one shown here specifies that we want to test as if we are running on API Level 16 (`sdk=JELLY_BEAN`), instead of our `targetSdkVersion`. The `sdk` property is not required, if your `targetSdkVersion` is a supported value. However, you may wish to still specify it on the tests, so your tests are isolated from changes that you might make to the `targetSdkVersion`.

To get a fully-initialized mock activity, call `Robolectric.setupActivity()`, providing the Java class object for the activity in question (e.g., `ActionBarFragmentActivity.class`). This works similarly to calling `getActivity()` on an `ActivityTestRule` in a JUnit4 instrumentation test: you get an activity, with the appropriate data type, ready for testing. In this case, we retrieve the `ListView` and, in a `@Test` method, ensure that the adapter in the `ListView` has 25 entries.

The instrumentation test edition of `DemoActivityTest` also tests key and touch events. While Robolectric supports `performClick()` calls on views to simulate click events, simulating key and touch events does not appear to be well-supported, which is why the Robolectric test case skips them.

Running Robolectric Tests

You run the Robolectric tests the same way as any other unit tests, such as by right-clicking over the test case class and choosing the run option.

The first time that you run the tests for your module, Robolectric will download a bunch of stuff:

```
/usr/lib/jvm/java-8-oracle/bin/java -ea -Didea.launcher.port=7535
-Didea.launcher.bin.path=/home/mmurphy/android-studio/bin -Dfile.encoding=UTF-8
-classpath /home/mmurphy/android-studio/lib/idea_rt.jar:/home/mmurphy/android-studio/

```

...then you failed to set the `sdk` property to a valid API level in your `@Config` annotation, as is described earlier in this chapter.

OK, So, Why Bother?

If input is limited and mocks are incomplete, why are we using Robolectric?

Robolectric can be useful in cases where you wish to run a quick subset of tests frequently to determine whether there are egregious problems. So-called “smoke tests” might be run on every commit to a version control system by a build server, for example. In this case, while Roboletric may not help you with test breadth or depth, it can help you with test frequency, since unit tests run so much faster. Running your full test suite on every commit might be too much; running the subset that you can implement as unit tests may be far more practical.

MonkeyRunner and the Test Monkey

Many GUI environments have some means or another of "fuzz" or "bash" testing, where some test driver executes a bunch of random input, in hopes of catching errors (e.g., missing validation logic). Android offers the Test Monkey for this.

Many GUI environments have some means or another of scripting GUI events from outside the application itself, to simulate button clicks or touch events. Android offers MonkeyRunner for this.

As the names suggest, there is a bit of commonality in their implementation. And, as you might expect, there is a bit of commonality in their coverage in this book — we will examine both MonkeyRunner and the Test Monkey in this chapter.

Prerequisites

Understanding this chapter requires that you have read the core chapters of this book.

MonkeyRunner

MonkeyRunner is a means of creating test suites for Android applications based on scripted UI input. Rather than write a series of JUnit test cases or the like, you create Jython (JVM implementation of Python) scripts that run commands to install apps, execute GUI events, and take screenshots of results.

Writing a MonkeyRunner Script

The primary object you will work with in a MonkeyRunner script is a `MonkeyDevice`, which represents your connection to the device or emulator that you are testing. You obtain a `MonkeyDevice` by calling `waitForConnection()` on `MonkeyRunner`; this will return once it has established a connection.

From there, `MonkeyDevice` lets you send events to the device or emulator:

- `installPackage()` allows you to install an APK from your development machine, and `removePackage()` allows you to get rid of it
- `startActivity()` and `broadcastIntent()` allow you to start up components of your app
- `press()` to simulate key events, including QWERTY keys, standard device keys like BACK, D-pad/trackball events, and anything else represented by a standard Android `KeyEvent`
- `type()` to simulate entering a whole string, as a simplification over calling `press()` once per letter
- `touch()` and `drag()` let you simulate touch events
- and so on

The biggest limitation is in getting data out of the device, to determine if your test worked successfully. Your options are:

- `takeSnapshot()`, which will capture a screenshot that you can save to disk, compare with other screenshots, etc.
- `shell()` executes `adb shell` commands, returning any results
- ...and that's about it

Unlike JUnit-based testing, you have no visibility into the activity beyond what appears on the screen — you cannot inspect widgets, call methods, or the like.

For example, here is a script that installs an app, runs an activity from it, and presses the down button on the D-pad three times:

```
from com.android.monkeyrunner import MonkeyRunner, MonkeyDevice

device = MonkeyRunner.waitForConnection()
device.installPackage('bin/JUnitDemo.apk')
device.startActivity(component='com.commonsware.android.abf/
com.commonsware.android.abf.ActionBarFragmentActivity')
device.press('KEYCODE_DPAD_DOWN', MonkeyDevice.DOWN_AND_UP)
device.press('KEYCODE_DPAD_DOWN', MonkeyDevice.DOWN_AND_UP)
device.press('KEYCODE_DPAD_DOWN', MonkeyDevice.DOWN_AND_UP)
```

```
# result = device.takeSnapshot()
# result.writeToFile('tests/monkey_sample_shots/test1.png', 'png')
```

(from Testing/monkey_sample.py)

Executing MonkeyRunner

To execute your MonkeyRunner script, have your device or emulator set up at a likely starting point (e.g., home screen), then execute the `monkeyrunner` command, passing it the path to your script (e.g., `monkeyrunner monkey_sample.py`). You will see the script executing on the screen of your device or emulator, and your console will contain whatever output you might emit from your test script itself. For example, you might take screenshots, compare them against a master copy (using methods on `MonkeyImage` to help with this), and emit warnings if they differ unexpectedly.

Monkeying Around

Independent from the JUnit system and MonkeyRunner is the Test Monkey (referred to here as "the Monkey" for short).

The Monkey is a test program that simulates random user input. It is designed for "bash testing", confirming that no matter what the user does, the application will not crash. The application may have odd results — random input entered into a Twitter client may, indeed, post that random input to Twitter. The Monkey does not test to make sure that results of random input make sense; it only tests to make sure random input does not blow up the program.

You can run the Monkey by setting up your initial starting point (e.g., the main activity in your application) on your device or emulator, then running a command like this:

```
adb shell monkey -p your.package.here -v --throttle 100 600
```

(substituting the application ID of a project on your device or emulator for `your.package.here`)

Working from right to left, we are asking for 600 simulated events, throttled to add 100 millisecond delays. We want to see a list of the invoked events (`-v`) and we want to throw out any event that might cause the Monkey to leave our application, as determined by the application ID (`-p your.package.here`).

Note that this truly is the application ID, not the package name. In simple apps — such as most of this book's samples — the package name *is* the application ID. But if you have modified the application ID in your `build.gradle` file (e.g., replaced the application ID for a product flavor), you will need to use the actual application ID here, not the package name. In general, despite any legacy documentation to the contrary, "package name" only affects code-generated classes like `R` and `BuildConfig`. Any other use of the term "package name" really is referring to the application ID.

The Monkey will simulate keypresses (both QWERTY and specialized hardware keys, like the volume controls), D-pad/trackball moves, and sliding the keyboard open or closed. Note that the latter may cause your emulator some confusion, as the emulator itself does not itself actually rotate, so you may end up with your screen appearing in landscape while the emulator is still, itself, portrait. Just rotate the emulator a couple of times (e.g., `<Ctrl>-<F12>`) to clear up the problem.

Also note that the throttle time is only used in between batches of related events. So, a batch of several touch events, or a pair of up/down events for a hardware key, will not be throttled. You can see this if you pass `-v -v -v` for "ultimate verbose mode" and look at the output, such as this snippet:

```
:Sending Key (ACTION_DOWN): 134    // KEYCODE_F4
:Sending Key (ACTION_UP): 134    // KEYCODE_F4
Sleeping for 100 milliseconds
:Sending Touch (ACTION_DOWN): 0:(1302.0,842.0)
:Sending Touch (ACTION_MOVE): 0:(1295.3395,838.0863)
:Sending Touch (ACTION_MOVE): 0:(1290.1539,827.0493)
:Sending Touch (ACTION_MOVE): 0:(1280.0454,826.9068)
:Sending Touch (ACTION_MOVE): 0:(1272.0161,816.8062)
:Sending Touch (ACTION_MOVE): 0:(1260.7244,810.8302)
:Sending Touch (ACTION_UP): 0:(1250.5455,801.67444)
Sleeping for 100 milliseconds
:Sending Key (ACTION_DOWN): 19    // KEYCODE_DPAD_UP
:Sending Key (ACTION_UP): 19    // KEYCODE_DPAD_UP
Sleeping for 100 milliseconds
:Sending Key (ACTION_DOWN): 68    // KEYCODE_GRAVE
:Sending Key (ACTION_UP): 68    // KEYCODE_GRAVE
Sleeping for 100 milliseconds
```

Here, we see actual messages where the throttling is applied ("Sleeping for 100 milliseconds"). Hence, the time it takes the Test Monkey to run a test will be at most the number of events times the throttle time, but due to event batching, it is usually substantially less than that. 25-30% of the maximum time seems typical.

For playing with a Monkey, the above command works fine. However, if you want to regularly test your application this way, you may need some measure of repeatability. After all, the particular set of input events that trigger your crash may not come up all that often, and without that repeatable scenario, it will be difficult to repair the bug, let alone test that the repair worked.

To deal with this, the Monkey offers the `-s` switch, where you provide a seed for the random number generator. By default, the Monkey creates its own seed, giving totally random results. If you supply the seed, while the sequence of events is random, it is random for that seed — repeatedly using the same seed will give you the same events. If you can arrange to detect a crash and know what seed was used to create that crash, you may well be able to reproduce the crash.

Trail: Rx

Java 8 Lambda Expressions

In 2016, Android app development gained some ability to use Java 8 programming constructs.

One of those changes was the release of Android 7.0, which introduced some Java 8-compatible classes, such as those in the `java.util.stream` package. These are new to API Level 24. Most likely, you will only start to use them once you raise your `minSdkVersion` to 24 or higher.

However, some features can be used on older devices. Notable among these are lambda expressions, the Java 8 equivalent of blocks or closures that you find in other programming languages. Lambda expressions can make your code a bit less verbose, particularly in places where you are making heavy use of listener interfaces or other forms of callback objects.

Getting all this to work requires some Gradle changes (to request Java 8 support in the build process), plus using the new lambda expression syntax. This chapter will show you all of this.

Prerequisites

Understanding this chapter requires that you have read the core chapters of the book. It does not require that you have prior experience with Java 8 lambda expressions.

However, having read the chapter on `RecyclerView` is a good idea, as the sample app in this chapter was originally shown there.

Also, you should now be using Android Studio 3.0, and its related build tools.

The Basic Idea

In Java programming prior to Java 8, we needed to create a lot of classes for minor roles, whether those classes were traditional Java classes, nested classes, or anonymous inner classes.

For example, suppose that you have an `ArrayList` of `Video` objects:

```
package com.commonsware.android.recyclerview.videolist;

import android.content.ContentUris;
import android.database.Cursor;
import android.net.Uri;
import android.provider.MediaStore;

class Video implements Comparable<Video> {
  final String title;
  final Uri videoUri;
  final String mimeType;

  Video(Cursor row) {
    this.title=
      row.getString(row.getColumnIndex(MediaStore.Video.Media.TITLE));
    this.videoUri=ContentUris.withAppendedId(
      MediaStore.Video.Media.EXTERNAL_CONTENT_URI,
      row.getInt(row.getColumnIndex(MediaStore.Video.Media._ID)));
    this.mimeType=
      row.getString(row.getColumnIndex(MediaStore.Video.Media.MIME_TYPE));
  }

  @Override
  public boolean equals(Object obj) {
    if (!(obj instanceof Video)) {
      return(false);
    }

    return(videoUri.equals(((Video)obj).videoUri));
  }

  @Override
  public int hashCode() {
    return(videoUri.hashCode());
  }

  @Override
  public int compareTo(Video video) {
```

```
    return(title.compareTo(video.title));
  }
}
```

(from Java8/VideoLambda/app/src/main/java/com/commonsware/android/recyclerview/videolist/Video.java)

You want to sort those videos by a custom algorithm: ascending by title, descending by title, etc.

That is easy enough with `Collections.sort()`:

```
Collections.sort(temp, new Comparator<Video>() {
  @Override
  public int compare(Video one, Video two) {
    return(one.compareTo(two));
  }
});
```

However, that is fairly verbose. Many languages offer a simpler syntax, where you can provide a "block" or "closure" that, in this case, would handle the comparison without having to create a subclass and implement a method.

Java 8 offers such a syntax, via lambda expressions:

```
        Collections.sort(newVideos,
          (one, two) -> one.compareTo(two));
```

(from Java8/VideoLambda/app/src/main/java/com/commonsware/android/recyclerview/videolist/MainActivity.java)

Here, we have replaced the `Comparator` anonymous inner class implementation with a single line of Java code, but having the same result. The compiler, under the covers, wraps your lambda expression in a suitable `Comparator` for use by the `sort()` method.

Using Lambda Expressions

With all that as prologue, let's look at how we can enable and employ lambda expressions in an Android application.

The code listings for this section come mostly from the `Java8/VideoLambda` sample project. This is a version of a sample app from the chapter on `RecyclerView`, where we query the `MediaStore` for available videos and show them in a list. There are a

couple of editions of that sample in the `RecyclerView` chapter, one of which shows the use of `DiffUtil`, and that sample also demonstrates lambda expressions.

Enabling Lambda Expressions

Prior to Android Studio 3.0 (and its associated build tools), lambda expression support was offered by Google through a different Java compiler, called Jack. Jack had issues, possibly due to a broken crown. Android Studio 3.0 eliminated Jack, offering lambda expression support by means of the classic `javac` compiler combined with updated version of the `dx` tool for creating Dalvik bytecode from Java bytecode.

So, nowadays, to use lambda expressions, so long as you are using current build tools, the only project change that you need is to indicate that your source and target are both Java 1.8:

```
apply plugin: 'com.android.application'

dependencies {
    implementation 'com.android.support:recyclerview-v7:26.1.0'
    implementation 'com.squareup.picasso:picasso:2.5.2'
}

android {
    compileSdkVersion 26

    defaultConfig {
        minSdkVersion 16
        targetSdkVersion 25
        applicationId 'com.commonsware.android.lambda.video'
    }

    compileOptions {
        sourceCompatibility JavaVersion.VERSION_1_8
        targetCompatibility JavaVersion.VERSION_1_8
    }
}
```

(from Java8/VideoLambda/app/build.gradle)

Replacing Listeners with Lambdas

Now, you can replace single-method anonymous inner class implementations with lambdas with relative ease.

The example lambda expression from earlier in this chapter comes from the `sortAndApply()` method of the `VideoAdapter` inside the `MainActivity` of the sample app. Given an `ArrayList` of `Video` objects, we need to sort them based on the user's requested sort order (ascending by default). We use lambda expressions, rather than custom `Comparator` anonymous inner classes, to do that sorting:

```
  private void sortAndApply(ArrayList<Video> newVideos) {
    if (sortAscending) {
      Collections.sort(newVideos,
        (one, two) -> one.compareTo(two));
    }
    else {
      Collections.sort(newVideos,
        (one, two) -> two.compareTo(one));
    }

    DiffUtil.Callback cb=new SimpleCallback<>(videos, newVideos);
    DiffUtil.DiffResult result=DiffUtil.calculateDiff(cb, true);

    videos=newVideos;
    result.dispatchUpdatesTo(this);
  }
```

(from Java8/VideoLambda/app/src/main/java/com/commonsware/android/recyclerview/videolist/MainActivity.java)

Here, each of our two lambda expressions:

- Has two parameters (the two objects passed into `compare()` of a `Comparator`), so they get wrapped in parentheses
- Has a single Java statement to be executed, so it stands alone after the arrow (`->`)

Other editions of this sample app have `RowController` implement the `OnClickListener` interface and implement `onClick()` to be able to respond to click events on our rows. This sample app uses a lambda expression instead:

```
package com.commonsware.android.recyclerview.videolist;

import android.content.ContentUris;
import android.content.Intent;
import android.database.Cursor;
import android.net.Uri;
import android.provider.MediaStore;
import android.support.v7.widget.RecyclerView;
import android.view.View;
```

```
import android.widget.ImageView;
import android.widget.TextView;
import com.squareup.picasso.Picasso;

class RowController extends RecyclerView.ViewHolder {
  private TextView title=null;
  private ImageView thumbnail=null;
  private Uri videoUri=null;
  private String videoMimeType=null;

  RowController(View row) {
    super(row);

    title=row.findViewById(android.R.id.text1);
    thumbnail=row.findViewById(R.id.thumbnail);

    row.setOnClickListener(view -> {
      Intent i=new Intent(Intent.ACTION_VIEW);

      i.setDataAndType(videoUri, videoMimeType);
      title.getContext().startActivity(i);
    });
  }

  void bindModel(Video video) {
    title.setText(video.title);

    videoUri=video.videoUri;
    videoMimeType=video.mimeType;

    Picasso.with(thumbnail.getContext())
      .load(videoUri.toString())
      .fit().centerCrop()
      .placeholder(R.drawable.ic_media_video_poster)
      .into(thumbnail);
  }
}
```

(from Java8/VideoLambda/app/src/main/java/com/commonsware/android/recyclerview/videolist/RowController.java)

Here, our lambda expression:

- Has one parameter, so we can skip the parentheses around it
- Has multiple Java statements to be executed, so they get wrapped in a standard Java block ({ and })

When Android Studio detects a place where you could use a lambda expression, it will mark the anonymous inner class as gray:

```
row.setOnClickListener(new View.OnClickListener() {
  @Override
  public void onClick(View view) {
    Intent i=new Intent(Intent.ACTION_VIEW);

    i.setDataAndType(videoUri, videoMimeType);
    title.getContext().startActivity(i);
  }
});
```

Figure 375: Potential Lambda Expression, in Android Studio

A quick-fix (e.g., Alt-Enter on Windows and Linux) will offer to convert it into a lambda expression for you.

Alternative: Method References

Our `Video` model class has a `compareTo()` implementation that our sorting lambda expressions rely upon:

```
package com.commonsware.android.recyclerview.videolist;

import android.content.ContentUris;
import android.database.Cursor;
import android.net.Uri;
import android.provider.MediaStore;

class Video implements Comparable<Video> {
  final String title;
  final Uri videoUri;
  final String mimeType;

  Video(Cursor row) {
    this.title=
      row.getString(row.getColumnIndex(MediaStore.Video.Media.TITLE));
    this.videoUri=ContentUris.withAppendedId(
      MediaStore.Video.Media.EXTERNAL_CONTENT_URI,
      row.getInt(row.getColumnIndex(MediaStore.Video.Media._ID)));
    this.mimeType=
      row.getString(row.getColumnIndex(MediaStore.Video.Media.MIME_TYPE));
  }
```

```
  @Override
  public boolean equals(Object obj) {
    if (!(obj instanceof Video)) {
      return(false);
    }

    return(videoUri.equals(((Video)obj).videoUri));
  }

  @Override
  public int hashCode() {
    return(videoUri.hashCode());
  }

  @Override
  public int compareTo(Video video) {
    return(title.compareTo(video.title));
  }
}
```

(from Java8/VideoLambda/app/src/main/java/com/commonsware/android/recyclerview/videolist/Video.java)

We can further simplify the sorting code by replacing the lambda expressions with a method reference... for the first such expression:

```
if (sortAscending) {
  Collections.sort(temp, Video::compareTo);
}
else {
  Collections.sort(temp,
    (one, two) -> two.compareTo(one));
}
```

Here, we are saying that we want to pass the parameters normally passed into `compare()` of a `Comparator` into the `compareTo()` method of the first parameter. You can similarly use method references to refer to static methods or a method on some separate object.

However, we cannot replace the second lambda expression with a method reference. The `Video::compareTo` method reference always calls the method on the first parameter. In our case, that is fine for the ascending sort, but for the descending sort, we would need to call `compareTo()` on the *second* parameter, as our lambda expression does. Alternatively, `Video` could implement another method (e.g., `compareDescendingTo()`) that we could use as a method reference.

Rx Basics

A programming model that has been gaining substantial ground in recent years is reactive programming. In Android, much of the attention has been on RxJava, the "reactive extensions for Java". Many libraries offer the ability to be consumed using RxJava, and many Android experts have latched onto RxJava as a way to reduce certain types of complexity in Android app development.

In this chapter, we will review what reactive programming is, what RxJava is, and how you can apply RxJava in your Android app.

However, please understand that reactive programming is a very large topic. Just a complete explanation of RxJava would entail its own book. This chapter should be seen as a launching pad for further explorations of your own, more so than a definitive reference on the subject.

Prerequisites

Understanding this chapter requires that you have read the core chapters of this book.

Life is But a Stream

In order to understand reactive programming, we first need to think about streams.

When a Java programmer hears the term "stream", what often pops into mind is `InputStream` and `OutputStream`. Those offer access to a stream of bytes, for input and output, respectively. Here, "stream" means that the bytes are available one at a time (though are often retrieved in a clump, such as an 8192-byte buffer), and that

once removed from the stream the bytes are considered to be "consumed" and are no longer available from the stream itself.

When Java programmers think of `InputStream` and `OutputStream`, what often pops into mind is `FileInputStream` and `FileOutputStream`. With `FileInputStream`, the source of the bytes is fixed: the contents of a designated file. With `FileOutputStream`, the destination of the bytes is fixed: once again, a designated file.

However, there are many other sources of `InputStream` and `OutputStream`. Some that you encounter in the book are:

- Streams on sockets, such as the `InputStream` that you get from `HttpUrlConnection`
- Streams on content from a `ContentProvider`, such as the `InputStream` that you get from calling `openInputStream()` on a `ContentProvider`

Particularly in the HTTP case, the source of the bytes is "live", insofar as there does not have to be some specific file that is the source of those bytes. Those bytes could represent a generated Web page, or a live audio stream, or anything else.

Hence, more generally, a stream represents a flow of data, where we can pull data off of the stream and do something with it. That "flow of data" could be bytes from a file, as we see with `InputStream`. But lots of other things could be modeled as flows of data. Pretty much anything where the data would come to us asynchronously could be modeled this way, such as:

- Sensor readings off of an accelerometer
- GPS fixes
- Touch events
- Audio signals from a microphone
- Preview or live video frames from a camera
- And so on

You could even model some things that might not feel like a "stream" as a stream if you wanted to. For example, querying a database or `ContentProvider` gives you a `Cursor` back, and you could model that as being a stream of rows.

Action and Reaction

Reactive programming works with streams. Rather than "iterate over the rows in the `Cursor` and do X to each", you say "as a row comes in from the stream of rows, do X to each". Here, you are "reacting" to the availability of a row.

But part of reactive programming is that what *processes* a stream might itself turn around and *be a stream* of events to something else. For example, given a stream of audio signals, you might implement a filter that clamps high-volume signals to a lower volume. That filter takes in a stream (raw signals) and emits another stream (clamped signals). Other code could react to the filtered stream (e.g., to record bytes to disk).

You may have already done reactive programming, without even realizing it. The world's most popular reactive programming environment is not some functional programming language or UI framework.

It's a spreadsheet.

Spreadsheet cells — particularly for simpler sheets — can be thought of as either having data (particularly numbers) or formulas. A formula references cells and performs a calculation upon them. This includes performing calculations upon other cells that contain formulas.

For example, you might have a spreadsheet like this:

	A	B
1		1
2		1
3		2
4		3
5		5
6	Average	**2.4**
7	Factor	1.1
8	Result	**2.64**

Figure 376: Simple Spreadsheet

Here, the two formulas are shown in bold, while the data cells are in the default font.

The average formula cell has `=AVERAGE(B1:B5)`, to compute the average of the five number cells above it. The result formula cell has `=B6*B7`, to multiply the average by the "factor" number.

If you change that factor, not only does that cell change, but so does the result formula cell. The B6 and B7 values referenced in the result formula do not just identify cells, but represent *streams of changes to those cells' values*. When B7 (the factor value) changes, the result formula reacts to the changed-value event and recalculates its formula, showing the result:

	A	B
1		1
2		1
3		2
4		3
5		5
6	Average	**2.4**
7	Factor	1.2
8	Result	**2.88**

Figure 377: Simple Spreadsheet with New Factor Value

Similarly, if you change one of the five initial values (1, 1, 2, 3, 5), the average formula cell responds to the changed-value event and recalculates its value. That, in turn, triggers a changed-value event that causes the result formula cell to react and recalculate *its* value:

	A	B
1		1
2		1
3		2
4		5
5		5
6	Average	**2.8**
7	Factor	1.2
8	Result	**3.36**

Figure 378: Simple Spreadsheet with New Initial and New Factor Value

A Rx For What Ails You

At this point, you may be wondering what this has to do with Android, or even Java.

The pre-eminent framework for reactive programming in Java — while sticking to Java syntax itself, versus using a functional JVM language like Scala or Clojure — is RxJava. RxJava is a library that helps you model data as streams and apply a chain of operations to those streams.

RxJava is part of the ReactiveX series of libraries, offering reactive programming for a wide range of programming languages and platforms.

In late 2016, RxJava 2 was released. This includes some refactoring of the original RxJava classes to comply with the Reactive Streams specification. This chapter focuses on RxJava 2. Some material that you read on RxJava might be using the original RxJava API. While pretty much everything done with classic RxJava can be done with RxJava2, some conversion may be required.

(BTW, for those of you wondering about the title of this section, Rx is an abbreviation for the word "prescription")

Rx and Lambdas

RxJava relies heavily on functions. Java is not a functional programming language, and so it does not have "functions" as standalone first-class units of programming.

Java 8 offers lambda expressions, which are akin to anonymous functions. RxJava supports Java 8 lambda expressions, and by using Android Studio 3.0 (and its related build tools), Android developers can use lambda expressions in projects with a `minSdkVersion` of 9 or higher.

The examples in this chapter use lambda expressions, as that will be the typical way that you see RxJava be used.

A Simple Stream

Back in the chapter on threads, we had the `Threads/AsyncTask` sample app, which demonstrated using an `AsyncTask`. There, our data source was a `static` Java array of strings, and we would not need an `AsyncTask` to "load" those into a list. However, to keep things simple, we pretended that it took real work to obtain those strings, and we used an `AsyncTask` to do that work in the background.

Let's explore reactive programming and RxJava by revamping that example, starting with the `Rx/Simple` sample project.

Adding the Dependency

RxJava is a library, available from Maven Central and JCenter. So, in a typical Android Studio project could add RxJava as a dependency in a module's `build.gradle` file:

```
apply plugin: 'com.android.application'

dependencies {
  implementation "com.android.support:support-fragment:27.0.2"
  implementation 'io.reactivex.rxjava2:rxjava:2.1.7'
}

android {
  compileSdkVersion 27
  buildToolsVersion '27.0.3'

  defaultConfig {
    minSdkVersion 15
    targetSdkVersion 27
  }

  compileOptions {
    sourceCompatibility JavaVersion.VERSION_1_8
    targetCompatibility JavaVersion.VERSION_1_8
  }
}
```

(from Rx/Simple/app/build.gradle)

Replacing the Loop

The original `AsyncTask` sample app has a `doInBackground()` method that looks a bit like this:

```
@Override
protected Void doInBackground(Void... unused) {
  for (String item : ITEMS) {
    if (isCancelled())
      break;

    publishProgress(item);
    SystemClock.sleep(400);
  }

  return(null);
}
```

Here, `ITEMS` is our `static` String array. We iterate over that array, and if our task has not been canceled, we call `publishProgress()` to add a string to our `ListView`, and sleep for 400 milliseconds as our way of pretending to do real work.

The first step towards switching to a reactive model is to replace that loop with a stream:

```
  @Override
  protected Void doInBackground(Void... unused) {
    Observable.fromArray(ITEMS).subscribe(s -> {
      if (!isCancelled()) {
        publishProgress(s);
        SystemClock.sleep(400);
      }
    });

    return(null);
  }
```

(from Rx/Simple/app/src/main/java/com/commonsware/android/rx/RxDemoFragment.java)

`io.reactivex.Observable` is the root class for most of what you will do with RxJava. It helps you set up a stream and then react to that stream.

There are several ways to set up a stream — we will see a few of them in this chapter. In this case, we are using `fromArray()`, which sets up a stream based on the items in that array. In reality, this is a factory method; the returned object is an `Observable`.

We then call `subscribe()` on the `Observable`. This basically represents the sink for the stream of data coming from the `Observable`. In this case, we use lambda expression implementation of the `Consumer` interface. Our lambda expression body implements the `accept()` method from that `Consumer` interface, and it will be invoked for each piece of data from the stream. In this case, `ITEMS` is an array of `String`, and so we are setting up a `Consumer` of `String` and therefore we `accept()` a `String`. Our lambda expression has our `isCancelled()` check, our `publishProgress()` call, and our `sleep()` call, as with the iterative loop from the original sample.

Be Your Own Stream

Our 400 milliseconds of `sleep()` is a way of simulating doing work. However, as RxJava is showing us, we are not actually simulating doing work to get the data.

Instead, we are simulating doing work to *consume* the data. Our `sleep()` call is in our `Consumer` (or the equivalent lambda expression), not in our data source.

However, we can model this better, by creating our own data source that is a bit more sophisticated than a simple `static` Java array.

The `Rx/Observable` sample project replaces `fromArray()` with a call to `create()`, which creates an `Observable` upon a supplied source of data:

```
@Override
protected Void doInBackground(Void... unused) {
  Observable.create(source())
    .subscribe(s -> {
      if (!isCancelled()) {
        publishProgress(s);
      }
    });

  return(null);
}

private ObservableOnSubscribe<String> source() {
  return(new ObservableOnSubscribe<String>() {
    @Override
    public void subscribe(ObservableEmitter<String> emitter) throws Exception {
      for (String item : ITEMS) {
        if (!isCancelled()) {
          emitter.onNext(item);
          SystemClock.sleep(400);
        }
      }

      emitter.onComplete();
    }
  });
}
```

Here, `source()` is returning an instance of an oddly-named `ObservableOnSubscribe` interface. An `ObservableOnSubscribe` is for cases where we are only actually starting to obtain data for our stream when something subscribes to the `Observable`, not before. In our case, that is fine, as we are still just using our `String` array.

An `ObservableOnSubscribe` implements a `subscribe()` method. This is called when a subscriber subscribes to the `Observable`. The job of `subscribe()` is to work with the underlying data and call three methods on the supplied `ObservableEmitter`:

- Call `onNext()`for each piece of data in the stream
- Call `onComplete()` when we are done with all possible data
- Call `onError()` if something fails (e.g., an `IOException` when reading from a socket)

In our case, we are iterating over our Java array, calling `onNext()` for each `String`, and sleeping the 400 milliseconds to simulate doing actual work.

Note that, if you want, you can replace the `ObservableOnSubscribe` with a lambda expression:

```
  private ObservableOnSubscribe<String> source() {
    return(emitter -> {
      for (String item : ITEMS) {
        if (!isCancelled()) {
          emitter.onNext(item);
          SystemClock.sleep(400);
        }
      }

      emitter.onComplete();
    });
  }
```

(from Rx/Observable/app/src/main/java/com/commonsware/android/rx/RxDemoFragment.java)

Removing the AsyncTask

At this point, you may be wondering why we are bothering with any of this, as our code gets more and more complex without any particular added value. This reaction is understandable. All we have done is make an `AsyncTask` more complicated.

So, let's get rid of the `AsyncTask`.

Part of the power of RxJava is thread management. You can tell it the threads to use for working with streams, such as doing I/O on a background thread. However, RxJava is a pure Java library. It knows nothing about Android and Android-specific constructs like the main application thread.

Fortunately, there is RxAndroid. This a small library adding some Android-specific smarts to RxJava, such as the notion of the main application thread. This, like RxJava, is available as an artifact:

```
apply plugin: 'com.android.application'

dependencies {
  implementation "com.android.support:support-fragment:27.0.2"
  implementation 'io.reactivex.rxjava2:rxjava:2.1.7'
  implementation 'io.reactivex.rxjava2:rxandroid:2.0.1'
}

android {
  compileSdkVersion 27
  buildToolsVersion '27.0.3'

  defaultConfig {
    minSdkVersion 15
    targetSdkVersion 27
    applicationId "com.commonsware.android.rx.rxandroid"
  }

  compileOptions {
    sourceCompatibility JavaVersion.VERSION_1_8
    targetCompatibility JavaVersion.VERSION_1_8
  }
}
```

(from Rx/RxAndroid/app/build.gradle)

With that in mind, let's look at the Rx/RxAndroid sample project and our substantially-revised `ListFragment`, here named `RxDemoFragment`:

```
package com.commonsware.android.rx;

import android.support.v4.app.ListFragment;
import android.os.Bundle;
import android.os.SystemClock;
import android.view.View;
import android.widget.ArrayAdapter;
import android.widget.Toast;
import java.util.ArrayList;
import io.reactivex.Observable;
import io.reactivex.ObservableOnSubscribe;
import io.reactivex.android.schedulers.AndroidSchedulers;
import io.reactivex.disposables.Disposable;
import io.reactivex.schedulers.Schedulers;

public class RxDemoFragment extends ListFragment {
  private static final String[] ITEMS= { "lorem", "ipsum", "dolor",
      "sit", "amet", "consectetuer", "adipiscing", "elit", "morbi",
      "vel", "ligula", "vitae", "arcu", "aliquet", "mollis", "etiam",
```

```
    "vel", "erat", "placerat", "ante", "porttitor", "sodales",
    "pellentesque", "augue", "purus" };
private ArrayList<String> model=new ArrayList<>();
private ArrayAdapter<String> adapter;
private Disposable sub=null;

@Override
public void onCreate(Bundle savedInstanceState) {
  super.onCreate(savedInstanceState);

  setRetainInstance(true);

  adapter=new ArrayAdapter<>(getActivity(),
    android.R.layout.simple_list_item_1, model);

  Observable<String> observable=Observable
    .create(source())
    .subscribeOn(Schedulers.newThread())
    .observeOn(AndroidSchedulers.mainThread())
    .doOnComplete(() -> {
      Toast.makeText(getActivity(), R.string.done, Toast.LENGTH_SHORT)
        .show();
    });

  sub=observable.subscribe(s -> {
    adapter.add(s);
  });
}

private ObservableOnSubscribe<String> source() {
  return(emitter -> {
    for (String item : ITEMS) {
      emitter.onNext(item);
      SystemClock.sleep(400);
    }

    emitter.onComplete();
  });
}

@Override
public void onViewCreated(View v, Bundle savedInstanceState) {
  super.onViewCreated(v, savedInstanceState);

  getListView().setScrollbarFadingEnabled(false);
  setListAdapter(adapter);
}
```

```
  @Override
  public void onDestroy() {
    if (sub!=null && !sub.isDisposed()) {
      sub.dispose();
    }

    super.onDestroy();
  }
}
```

(from Rx/RxAndroid/app/src/main/java/com/commonsware/android/rx/RxDemoFragment.java)

Some things are the same as in the original sample app: the `static` array, the `ArrayList` model, the `ArrayAdapter`, the retained fragment, etc.

However, our `AsyncTask` is gone, replaced by a chunk of RxJava code:

```
  @Override
  public void onCreate(Bundle savedInstanceState) {
    super.onCreate(savedInstanceState);

    setRetainInstance(true);

    adapter=new ArrayAdapter<>(getActivity(),
      android.R.layout.simple_list_item_1, model);

    Observable<String> observable=Observable
      .create(source())
      .subscribeOn(Schedulers.newThread())
      .observeOn(AndroidSchedulers.mainThread())
      .doOnComplete(() -> {
        Toast.makeText(getActivity(), R.string.done, Toast.LENGTH_SHORT)
          .show();
      });

    sub=observable.subscribe(s -> {
      adapter.add(s);
    });
  }
```

(from Rx/RxAndroid/app/src/main/java/com/commonsware/android/rx/RxDemoFragment.java)

This code adds a number of items to our `Observerable` call chain, so let's take them one at a time.

subscribeOn()

This teaches RxJava the code to use for invoking our `ObservableOnSubscribe` code, specifically its `subscribe()` method (or the equivalent with a lambda expression). Since `subscribe()` could take some time — in our case, 400 milliseconds per string — we really want to run that on a background thread.

The `Schedulers` utility class in RxJava provides a handful of options for indicating the thread to use. Here, we are using `newThread()`, which does pretty much what the name suggests: create a new thread and use that for our `subscribe()` work.

Typically, if we are using RxJava and RxAndroid, we want to subscribe to events on a background thread. That is not always the case, though. There are techniques for using RxJava/RxAndroid to manage things like user input (e.g., text being entered live in an `EditText`). In those cases, we may have specific threading requirements, such as subscribing on Android's main application thread.

observeOn()

By default, if you use `subscribeOn()`, *everything* involved with this stream will be done on that thread. This would include the work we want to do to update our UI, via our `subscribe()` call. And, on Android, we cannot update the UI from a background thread.

`observeOn()` basically says "for everything in this `Observable` configuration from this point forward should switch to using this other thread". With our `subscribe()` call coming after `observeOn()`, we wind up processing our `subscribe()` work in the thread indicated by `observeOn()`.

Here, we use RxAndroid and its `AndroidSchedulers` class, which has a `mainThread()` method to indicate that we want the work to be done on the main application thread.

Note that you can call `observeOn()` several times. Typically, this is not necessary. But, for example, you might use `subscribeOn()` to receive some UI event on the main application thread, then call `observeOn()` to direct initial processing of that event onto a background thread (e.g., database I/O for updating a live filter based on what has been typed in so far), then call `observeOn()` *again* to direct further processing to the main application thread (e.g., update a `RecyclerView` with the now-filtered results).

doOnComplete()

In our samples so far, in the `onPostExecute()` method of our `AsyncTask`, we showed a `Toast` to signal that the work was completed.

The equivalent step in RxJava is `doOnComplete()`. This takes an `Action` object or, in this case, a lambda expression. This will be called when our `source()` triggers `onCompleted()` on its supplied `emitter`. Here, we show the `Toast`, after confirming that we have not been canceled.

subscribe()

We then `subscribe()` to the `Observable`, feeding the strings into our `ArrayAdapter`. `subscribe()` returns a `Disposable` instance, which we hold onto in a field.

On a configuration change, we retain the `Disposable`, which in turn holds onto our `Observable`. We also retain the `ArrayAdapter`. So, the new activity and new fragment connect back up to the `ArrayAdapter`, and they get all existing words plus any new ones fed in by our ongoing Rx work, if that has not completed already.

If the user presses BACK to exit the activity, or the activity otherwise is being finally destroyed, `onDestroy()` is called on our retained fragment, and there we `dispose()` of that `Disposable`:

```
@Override
public void onDestroy() {
  if (sub!=null && !sub.isDisposed()) {
    sub.dispose();
  }

  super.onDestroy();
}
```

(from Rx/RxAndroid/app/src/main/java/com/commonsware/android/rx/RxDemoFragment.java)

This way, if the Rx background work is still going on, and the fragment is being destroyed, we disconnect and do not try to continue updating the `ArrayAdapter` or display the `Toast`, as neither of those things are safe with a destroyed activity.

Lambdas and Lifetimes

Be careful about what you reference from lambda expressions tied into RxJava, or their anonymous inner class counterparts. You need to ensure that the lambdas only reference objects with the same intended lifespan as the lambda itself.

In particular, be careful about referencing widgets directly. Suppose that we had some RxJava work that was delivering a `String` to be filled into an `EditText`. From a retained fragment, you might try doing something like this:

```
Observable<String> observable=Observable
  .create(source())
  .subscribeOn(Schedulers.newThread())
  .observeOn(AndroidSchedulers.mainThread());

sub=observable.subscribe(s -> {
  myAwesomeEditText.setText(s);
});
```

The problem here is that `myAwesomeEditText` is a specific `EditText` instance, the one known about at the time when the lambda expression is created. If we undergo a configuration change, our fragment winds up retaining the lambda expression *but creating a new `EditText`*. However, our lambda expression does not know about that new `EditText`, so it happily sets the text of the old `EditText`, with unfortunate results.

A safer approach is to call a method:

```
Observable<String> observable=Observable
  .create(source())
  .subscribeOn(Schedulers.newThread())
  .observeOn(AndroidSchedulers.mainThread());

sub=observable.subscribe(s -> {
  updateMyAwesomeEditText(s);
});
```

where the method on the fragment can refer to the proper `EditText` instance, whichever one is current at the time that the lambda expression is evaluated.

Streaming from a Resource

Of course, this still uses a 400-millisecond `sleep()` call to simulate real work. The next step would be to do some actual I/O here, taking advantage of RxJava's ability to pull data from the stream on a background thread.

The Rx/XML sample project places our 25 Latin words in an XML resource:

```
<words>
  <word value="lorem" />
  <word value="ipsum" />
  <word value="dolor" />
  <word value="sit" />
  <word value="amet" />
  <word value="consectetuer" />
  <word value="adipiscing" />
  <word value="elit" />
  <word value="morbi" />
  <word value="vel" />
  <word value="ligula" />
  <word value="vitae" />
  <word value="arcu" />
  <word value="aliquet" />
  <word value="mollis" />
  <word value="etiam" />
  <word value="vel" />
  <word value="erat" />
  <word value="placerat" />
  <word value="ante" />
  <word value="porttitor" />
  <word value="sodales" />
  <word value="pellentesque" />
  <word value="augue" />
  <word value="purus" />
</words>
```

(from Rx/XML/app/src/main/res/xml/words.xml)

We can then create an `ObservableOnSubscribe` implementation that reads in those words, using an `XmlPullParser` obtained from a `Resources` object, and use those words for our `onNext()` calls:

```
  private static class WordSource implements ObservableOnSubscribe<String> {
    private final Resources resources;
```

```
    WordSource(Context ctxt) {
      resources=ctxt.getResources();
    }

    @Override
    public void subscribe(ObservableEmitter<String> emitter) {
      try {
        XmlPullParser xpp=resources.getXml(R.xml.words);

        while (xpp.getEventType()!=XmlPullParser.END_DOCUMENT) {
          if (xpp.getEventType()==XmlPullParser.START_TAG) {
            if (xpp.getName().equals("word")) {
              emitter.onNext(xpp.getAttributeValue(0));
            }
          }

          xpp.next();
        }

        emitter.onComplete();
      }
      catch (Exception e) {
        emitter.onError(e);
      }
    }
  }
}
```

(from Rx/XML/app/src/main/java/com/commonsware/android/rx/RxDemoFragment.java)

Error Handling

If you look closely at that code snippet, you will see that we are using a third method on the `ObservableEmitter`: `onError()`. We call this when something goes wrong in reading in the XML, passing the exception along to the emitter.

That, in turn, can make it to the code in our `subscribe()` call:

```
@Override
public void onCreate(Bundle savedInstanceState) {
  super.onCreate(savedInstanceState);

  adapter=new ArrayAdapter<>(getActivity(),
    android.R.layout.simple_list_item_1, model);

  Observable<String> observable=Observable
    .create(new WordSource(getActivity()))
    .subscribeOn(Schedulers.io())
```

```
    .map(s -> (s.toUpperCase()))
    .observeOn(AndroidSchedulers.mainThread())
    .doOnComplete(() ->
      Toast.makeText(getActivity(), R.string.done, Toast.LENGTH_SHORT).show());

  sub=observable.subscribe(s -> adapter.add(s),
      error ->
        Toast
          .makeText(getActivity(), error.getMessage(), Toast.LENGTH_LONG)
          .show());
}
```

(from Rx/XML/app/src/main/java/com/commonsware/android/rx/RxDemoFragment.java)

Now, we are using a two-parameter implementation of `subscribe()` and are passing in two lambda expressions. The first provides us our data, which we pass to the `ArrayAdapter` as before. The second lambda will be called if an exception is encountered and supplied to our `emitter` and its `onError()` method. Here, we get the error, and use its message to show a `Toast`.

Transmogrification

If you look closely at *that* code snippet, we have two other changes, compared to the earlier RxAndroid sample.

One is that we are using `Schedulers.io()`, instead of `Schedulers.newThread()`. RxJava has a thread dedicated for I/O concerns, which we are using here. That is not a requirement, and for more sophisticated scenarios you might need something else (e.g., a thread from a thread pool that you configure and manage). Here, we are just illustrating more than one way to move our I/O code off the main application thread.

The second change, while small here, is more profound in general. We are calling `map()`, passing in a lambda expression that takes a `String` and converts it to uppercase. If you run this sample app, you will see that all of the words show up in uppercase (and quickly, since reading words out of an XML resource happens much faster than one word every 400 milliseconds).

`map()` is known as an operator. Its job is to take a stream as input and emit another stream as output, executing some code on each item in the stream to change it, somehow.

There are *lots* of operators built into RxJava, handling all sorts of scenarios, such as filtering:

- `skip()` ignores a specified number of items, not passing them downstream
- `take()` accepts a specified number of items, ignoring the rest
- `distinct()` skips any items that appeared before, using `equals()` by default

The `takeUntil()` method that we have been calling is another operator, saying "take all items from the main `Observable` until this other `Observable` says otherwise".

Other operators aggregate or convert the stream, such as:

- `concat()` takes two `Observables` and emits the items from the first, followed by the items from the second
- `count()` counts the items and emits a single-item stream containing the count of the original stream's items
- `reduce()` applies some supplied lambda expression (or the equivalent) to calculate some result (e.g., an average), emitting a single-item stream containing that result

RxJava alone has perhaps a hundred operators, and you can create others if none of the built-in ones meet your needs.

Rx-Enabled Libraries

Many libraries either offer an Rx-compatible API as part of their base functionality or offer an Rx-compatible bridge between your code and some existing, non-Rx-compatible API.

For example, Retrofit offers an RxJava 2-compatible adapter for Retrofit 2.x.

The `Rx/Retrofit` sample project is a clone of the original Retrofit 2.x sample from the chapter on Internet access, revised to use RxJava bindings instead of Retrofit's built-in asynchronous options.

The dependencies now include the RxJava 2 adapter for Retrofit, plus RxAndroid — these, in turn, will pull in RxJava:

```
apply plugin: 'com.android.application'

dependencies {
    implementation 'com.squareup.picasso:picasso:2.5.2'
    implementation 'com.squareup.retrofit2:converter-gson:2.3.0'
    implementation 'com.squareup.retrofit2:adapter-rxjava2:2.3.0'
    implementation ("com.android.support:support-v4:27.0.2") {
```

```
        exclude group: 'com.android.support', module: 'support-media-compat'
    } // for https://issuetracker.google.com/issues/64909326
    implementation 'io.reactivex.rxjava2:rxjava:2.1.7'
    implementation 'io.reactivex.rxjava2:rxandroid:2.0.1'
}

android {
    compileSdkVersion 27
    buildToolsVersion '27.0.3'

    defaultConfig {
        minSdkVersion 15
        targetSdkVersion 27
        versionCode 1
        versionName "1.0"
        applicationId "com.commonsware.android.rx.retrofit"
    }

    dataBinding {
        enabled = true
    }

    compileOptions {
        sourceCompatibility JavaVersion.VERSION_1_8
        targetCompatibility JavaVersion.VERSION_1_8
    }
}
```

(from Rx/Retrofit/app/build.gradle)

Now, though, `StackOverflowInterface` can return an `Observable`, rather than a `Call`:

```
package com.commonsware.android.databind.basic;

import io.reactivex.Observable;
import retrofit2.Call;
import retrofit2.Callback;
import retrofit2.http.GET;
import retrofit2.http.Path;
import retrofit2.http.Query;

public interface StackOverflowInterface {
  @GET("/2.1/questions?order=desc&sort=creation&site=stackoverflow")
  Observable<SOQuestions> questions(@Query("tagged") String tags);

  @GET("/2.1/questions/{ids}?site=stackoverflow")
```

```
  Observable<SOQuestions> update(@Path("ids") String questionIds);
}
```

(from Rx/Retrofit/app/src/main/java/com/commonsware/android/databind/basic/StackOverflowInterface.java)

This gives us an `Observable` on a stream, just as if we had called `Observable.fromArray()` or `Observable.create()`. In this case, the "stream" is a single-item stream, containing an `SOQuestions` payload, which is our parsed response from the Stack Exchange API.

That, in turn, allows our `QuestionsFragment` to use RxJava to arrange to perform the I/O on the `io()` thread, process the response on the Android main application thread, plus process our questions or any errors that may crop up:

```
    so.questions("android")
      .subscribeOn(Schedulers.io())
      .observeOn(AndroidSchedulers.mainThread())
      .subscribe(result1 -> {
          for (Item item : result1.items) {
            Question question=new Question(item);

            questions.add(question);
            questionMap.put(question.id, question);
          }

          setListAdapter(new QuestionsAdapter(questions));
        }, t -> {
          Toast.makeText(getActivity(), t.getMessage(),
            Toast.LENGTH_LONG).show();
          Log.e(getClass().getSimpleName(),
            "Exception from Retrofit request to StackOverflow", t);
        }
      );
```

(from Rx/Retrofit/app/src/main/java/com/commonsware/android/databind/basic/QuestionsFragment.java)

Further Reading

The primary source of documentation on RxJava comes in the form of the GitHub repo's wiki.

JavaDocs of the RxJava 2 API are also available.

What About LiveData?

In 2017, Google introduced the Architecture Components: a set of libraries designed to offer higher-level abstractions around core architecture concerns. One piece of the Architecture Components is `LiveData`, which aims to offer a simpler approach to the same reactive pattern that is espoused in RxJava/RxAndroid.

`LiveData` is covered in the companion volume, "Android's Architecture Components".

Trail: Advanced UI

Notifications

Pop-up messages. Tray icons and their associated "bubble" messages. Bouncing dock icons. You are no doubt used to programs trying to get your attention, sometimes for good reason.

Your phone also probably chirps at you for more than just incoming calls: low battery, alarm clocks, appointment notifications, incoming text message or email, etc.

Not surprisingly, Android has a whole framework for dealing with these sorts of things, collectively called "notifications".

Prerequisites

Understanding this chapter requires you to have read the core chapters of the book.

What's a Notification?

A service, running in the background, needs a way to let users know something of interest has occurred, such as when email has been received. Moreover, the service may need some way to steer the user to an activity where they can act upon the event — reading a received message, for example. For this, Android supplies status bar icons, flashing lights, and other indicators collectively known as "notifications".

Your current phone may well have such icons, to indicate battery life, signal strength, whether Bluetooth is enabled, and the like. With Android, applications can add their own status bar icons, with an eye towards having them appear only when needed (e.g., a message has arrived).

Notifications will appear in one of two places. On most devices, they will appear in the status bar, on the top of the screen, left-aligned:

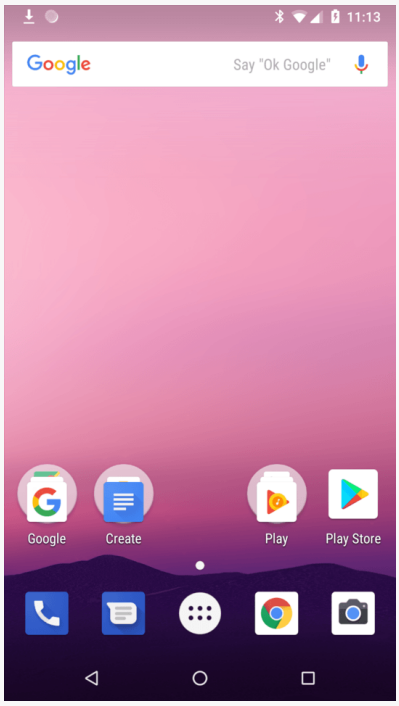

Figure 379: Notifications, on a Nexus 5X

On a pre-Android 4.2 tablet (and occasionally on other tablets newer than that), they will appear in the system bar, on the bottom of the screen, towards the lower-right corner:

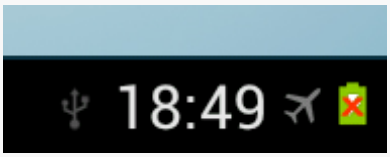

Figure 380: Notifications, on a Galaxy Tab 2

In either case, you can expand the “notification shade” to get more details about the active notifications, either by sliding down the status bar:

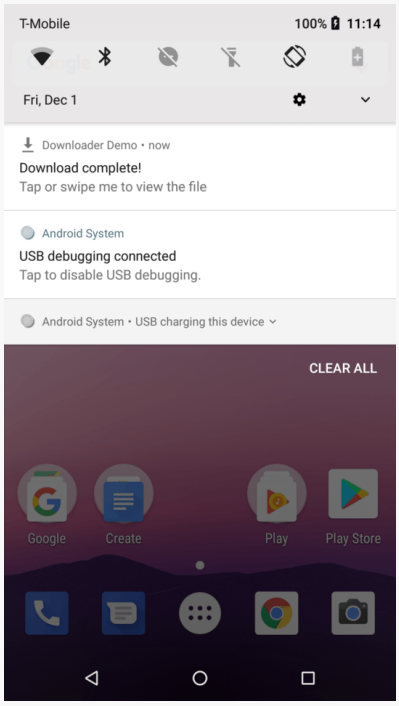

Figure 381: Notification Shade, on a Galaxy Nexus

or by tapping on the clock on the system bar on some tablets:

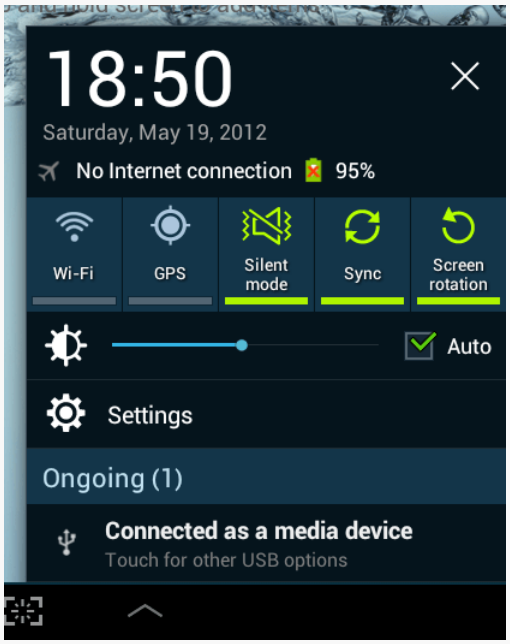

Figure 382: Notification Shade, on a Galaxy Tab 2

Some notifications will be complex, showing real-time information, such as the progress of a long download. More often, notifications are fairly simple, providing just a couple of lines of information, plus an identifying icon. Tapping on the notification shade entry will typically trigger some action, such as starting an activity — an email app letting the user know that "you've got mail" can have its notification bring up the inbox activity when tapped.

Notifications and Channels

Through Android 7.1, all notifications were created equal. In other words, the user could apply a single set of rules for configuring how those notifications were delivered from your app. How *much* configuration was even available varied by Android OS version, but on newer devices users could control whether to block those notifications, show them without any sound or vibration, what amount of information should be shown on the lockscreen, and so on.

In Android 8.0, all notifications go into channels that you define. The user then has the ability to control the behavior of notifications on a per-channel basis. This offers finer granularity of control over the breadth of notifications that your app might deliver. Android 8.0 also extends the depth of control, with more options for the user to decide how a channel's notifications should work.

Channels are not an optional feature, once your `targetSdkVersion` rises to `26` or higher. As a result, you will wind up with code that configures channels on API Level 26+ devices and code that configures notifications directly on older devices. This is aggravating, but is simply part of what is required.

In this chapter, we will show basic notification channel setup. In a later chapter, we will explore channels in greater detail.

Showing a Simple Notification

Suppose we want to download a file. That may take some time, depending on the size of the file. It would be nice to let the user know when the download has been completed. Ideally, we would let the user know by some means other than popping up a `Toast`. If we are having a service download the file — which is a good idea for longer downloads — there is the possibility that our UI is no longer in the foreground at the time the download is done, so we cannot necessarily update the UI to let the user know the file is ready for use.

An alternative would be for the background service doing the download to raise a `Notification` when the download is complete. That would work even if the activity was no longer around (e.g., user pressed BACK to exit it). This can be seen in the `Notifications/DownloadNotify` sample project. This is a slightly modified clone of the download-a-PDF-file sample from the chapter on services.

Our `DownloadFragment` for triggering the download dispenses with the `BroadcastReceiver` and logic related to it, including disabling and enabling the `Button`. Otherwise, it is the same as before.

The download logic in the `onHandleIntent()` method of `Downloader` is nearly identical as well, with two changes.

One change is that we pull out the MIME type of the response from its response header:

```
    URL url=new URL(i.getData().toString());
    HttpURLConnection c=(HttpURLConnection)url.openConnection();
    FileOutputStream fos=new FileOutputStream(output.getPath());
    BufferedOutputStream out=new BufferedOutputStream(fos);
    String mimeType=c.getHeaderField("Content-type");
```

(from Notifications/DownloadNotify/app/src/main/java/com/commonsware/android/downloader/Downloader.java)

The other difference is that at the end, rather than sending a broadcast `Intent`, we call a private `raiseNotification()` method. We also call this method if there is an exception during the download. The `raiseNotification()` method takes the MIME type that we collected earlier, the `File` object representing the downloaded results (if we succeeded), and the `Exception` that was raised (if we crashed). As one might guess given the method's name, `raiseNotification()` will raise a `Notification`:

```
private void raiseNotification(String mimeType, File output,
                               Exception e) {
  NotificationManager mgr=
    (NotificationManager)getSystemService(NOTIFICATION_SERVICE);

  if (Build.VERSION.SDK_INT>=Build.VERSION_CODES.O &&
    mgr.getNotificationChannel(CHANNEL_WHATEVER)==null) {
    mgr.createNotificationChannel(new NotificationChannel(CHANNEL_WHATEVER,
      "Whatever", NotificationManager.IMPORTANCE_DEFAULT));
  }

  NotificationCompat.Builder b=
    new NotificationCompat.Builder(this, CHANNEL_WHATEVER);
```

```
    b.setAutoCancel(true);

    if (e == null) {
      b.setContentTitle(getString(R.string.download_complete))
       .setContentText(getString(R.string.fun))
       .setSmallIcon(android.R.drawable.stat_sys_download_done);

      Intent outbound=new Intent(Intent.ACTION_VIEW);
      Uri outputUri=
        FileProvider.getUriForFile(this, AUTHORITY, output);

      outbound.setDataAndType(outputUri, mimeType);
      outbound.addFlags(Intent.FLAG_GRANT_READ_URI_PERMISSION);

      PendingIntent pi=PendingIntent.getActivity(this, 0,
        outbound, PendingIntent.FLAG_UPDATE_CURRENT);

      b.setContentIntent(pi);
    }
    else {
      b.setContentTitle(getString(R.string.exception))
       .setContentText(e.getMessage())
       .setSmallIcon(android.R.drawable.stat_notify_error);
    }

    mgr.notify(NOTIFY_ID, b.build());
  }
```

(from Notifications/DownloadNotify/app/src/main/java/com/commonsware/android/downloader/Downloader.java)

The first thing we do in `raiseNotification()` is get a `NotificationManager`, which is a system service. Calling `getSystemService()` and asking for the `NOTIFICATION_SERVICE` will give us our `NotificationManager`, albeit after a cast.

Next, we need to consider setting up a notification channel. This is required on API Level 26+ devices, because our project's `targetSdkVersion` is 26. We need to give the channel some unique identifier, here labeled `CHANNEL_WHATEVER`:

```
  private static final String CHANNEL_WHATEVER="channel_whatever";
```

(from Notifications/DownloadNotify/app/src/main/java/com/commonsware/android/downloader/Downloader.java)

`getNotificationChannel()`, on API Level 26+ devices, will return `null` if the channel is not defined. So, if we are on an API Level 26+ device and the channel is

not defined, we call `createNotificationChannel()` to define our channel. `createNotificationChannel()` takes three parameters:

- the channel identifier (`CHANNEL_WHATEVER`)
- a label to show the user that describes this channel (`"Whatever"`)
- the "importance" of this channel (`NotificationManager.IMPORTANCE_DEFAULT`)

We will cover the concept of "importance" in a later chapter. For now, take it on faith that `IMPORTANCE_DEFAULT` is a reasonable choice for most channels.

Then, we create a `NotificationCompat.Builder` object to help construct the `Notification`. On API Level 11 and higher, there is a `Notification.Builder` class that you can use. However, the notification system in Android has been changing frequently over the past few OS updates, and there are signs that this will continue. Hence, you may prefer to use `NotificationCompat.Builder`. First, this will work back to API Level 4, in case you are supporting notifications on older devices. More importantly, `NotificationCompat.Builder` is updated to reflect the latest `Notification.Builder` API, offering a backwards-compatible implementation of that API. Some newer features are not supported on older devices, but the `NotificationCompat.Builder` API lets you code to the new API, and it quietly ignores things that cannot be done on older devices.

The `NotificationCompat.Builder` constructor takes a `Context` plus the identifier of the channel that will be used. That channel identifier will be used on API Level 26+ devices and ignored otherwise. Here, we provide the `CHANNEL_WHATEVER` identifier that we just set up.

We can call methods on the `Builder` to configure the `Notification` that we want to display. Whether our download succeeded or failed, we call `setAutoCancel(true)` on the `Builder`, which means that when the user slides open the notification shade and taps on our entry, the `Notification` is automatically canceled and goes away.

If we succeeded (the passed-in `Exception` is `null`), we further configure our `Notification` via more calls to the `Builder`:

- `setContentTitle()` and `setContentText()` supply the prose to display in the two lines of the notification shade entry for our `Notification`
- `setSmallIcon()` indicates the icon to display in the status bar or system bar when the `Notification` is active (in this case, specifying one supplied by Android itself)

- `setTicker()` supplies some text to be displayed in the status bar or system bar for a few seconds right when the `Notification` is displayed, so users who happen to be looking at their device at that time will get more information at a glance about what just happened that is demanding their attention (though only on Android 4.4 and older devices, as the ticker was discontinued with Android 5.0)

In addition, `setContentIntent()` supplies a `PendingIntent` to be invoked when the notification shade entry for our `Notification` is tapped. In our case, we create an `ACTION_VIEW` `Intent` for our file. To do this, we use `FileProvider.getUriForFile()`, as we are serving this PDF via a `FileProvider`. Hence, if the user taps on our notification shade entry, we will attempt to bring up a PDF viewer on the downloaded PDF file – whether this will succeed or not will depend upon whether there is a PDF viewer installed on the device.

If, instead, we did have an `Exception`, we use the same methods on `Builder` (minus `setContentIntent()`) to configure the `Notification`, but using different text and icons.

Then, we can call `notify()` on the `NotificationManager`, supplying our `Notification` (from `build()` on the `Builder`) and a locally-unique integer (`NOTIFY_ID`, defined as a static data member on the service). That integer can later be used with a `cancel()` method to remove the `Notification` from the screen, even if the user has not canceled it themselves (e.g., via tapping on it with `setAutoCancel(true)`).

Running this in a device or emulator will display the `Notification` upon completion of the download, with the download icon:

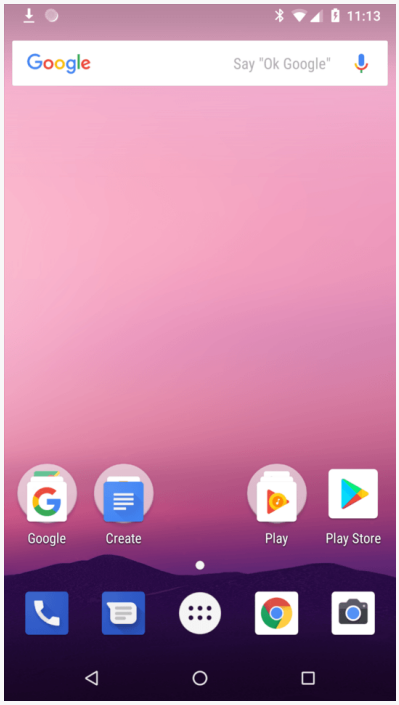

Figure 383: Sample Notification, on a Nexus 5X

Opening the notification shade displays our `Notification` details:

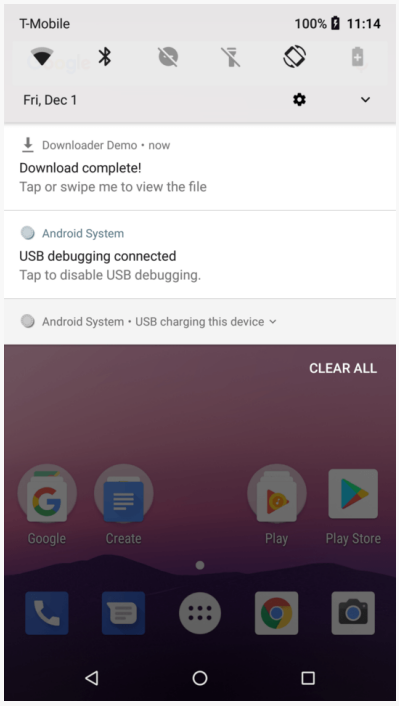

Figure 384: Sample Notification in Shade, on a Nexus 5X

Tapping on the shade entry will try to start a PDF viewer, perhaps bringing up a chooser if there are multiple such viewers on the device. Also, tapping on the shade entry will cancel the `Notification` and remove it from the screen.

The Activity-Or-Notification Scenario

Let us suppose that you are writing an email app. In addition to an "inbox" activity, you have an `IntentService`, scheduled via `AlarmManager`, to go check for new email messages every so often. This means, when your service discovers and downloads new messages, there are two possibilities:

- The user has your inbox activity in the foreground, and that activity should update to reflect the fact that there are new messages
- The user does *not* have your inbox activity in the foreground, so you want to display a `Notification` to alert the user of the new messages and lead them back to the inbox

However, ideally, the service neither knows nor cares whether the inbox activity is in the foreground, exists in the process but is not in the foreground, or does not exist

in the process (e.g., Android started a new process to handle this middle-of-the-night check for new email messages).

One way to handle this is via an event bus.

The recipe for the `Activity`-or-`Notification` pattern is:

1. Define an event (e.g., event class for greenrobot's EventBus, custom action string for `LocalBroadcastManager`)
2. Have your activity or fragment register to respond to these events while in the foreground (e.g., in `onResume()`) and unregister when leaving the foreground (e.g., `onPause()`). The activity or fragment can then update the UI in response to the event.
3. The service raises the event bus event at appropriate times.
4. By some means appropriate to the event bus implementation, the service needs to know whether an activity or fragment responded to the event, so it can raise a `Notification` if the event has not already been handled.

We will see three implementations of this pattern in the chapter on event bus alternatives.

Big (and Rich) Notifications

Android 4.1 introduced new `Notification` styles that automatically expand into a "big" area when they are the top `Notification` in the shade. These expanded `Notifications` can display more text (or a larger thumbnail of an image), plus add some action buttons to allow the user to directly perform more actions straight from the `Notification` itself.

And while these new `Notification` styles are only available on API Level 16 and higher, a familiar face has created a compatibility layer so our code can request the larger styles and still work on older devices.

The Styles

There are three main styles supplied for expanded `Notifications`. There is the `BigText` style:

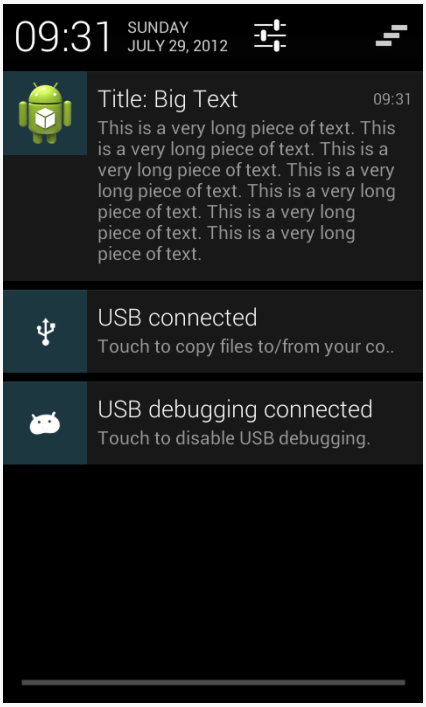

Figure 385: BigText Notification

We also have the `Inbox` style, which is the same basic concept but designed for several discrete lines of text:

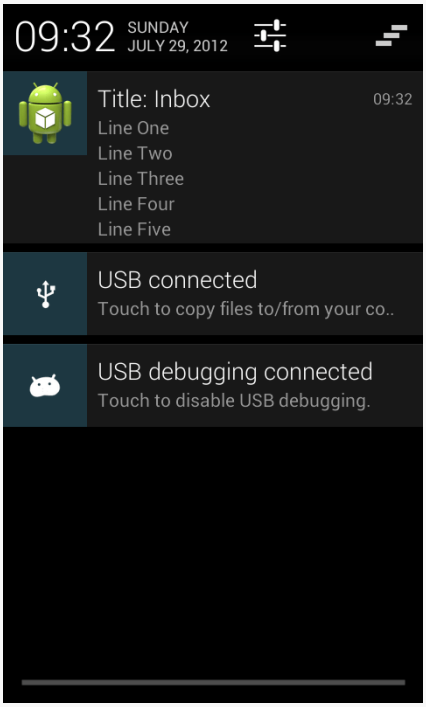

Figure 386: Inbox Notification

And, we have the `BigPicture` style, ideal for a photo, album cover, or the like:

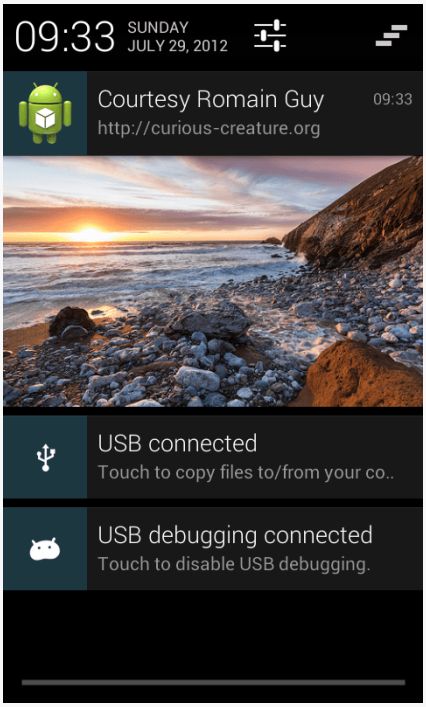

Figure 387: BigPicture Notification

(as noted in the screenshot, the photo is courtesy of Romain Guy, a former engineer on the core Android team and photography buff)

The Builders

`Notification.Builder` and `NotificationCompat.Builder` have been enhanced to support these new styles. Specifically:

- There is an `addAction()` method on the `Builder` class to define the action buttons, in terms of icon, caption, and `PendingIntent` that should be executed when the button is clicked
- There are style-specific builders, such as `Notification.InboxStyle`, that take a `Notification.Builder` and define the alternative expanded definition to be used when the `Notification` is at the top

The Sample

To see expanded notifications, take a peek at the `Notifications/BigNotify` sample application. This application consists of a single activity (`MainActivity`) that will raise a `Notification` and `finish()`, using `@style/Theme.Translucent.NoTitleBar`

to suppress the activity's own UI. Hence, the result of running the app is to display the `Notification` and do nothing else. While silly, it minimizes the amount of ancillary code involved in the project.

The process of displaying an expanded `Notification` is to first create the basic `Notification`, containing what you want to display for any non-expanded circumstance:

- Older devices that cannot display expanded `Notifications`, or
- Newer devices where the `Notification` is not the top-most entry in the notification shade, and therefore appears in the classic non-expanded form

Hence, in `onCreate()`, after getting our hands on a `NotificationManager`, we create a notification channel (if needed), then use `NotificationCompat.Builder` to create a regular `Notification`, wrapped in a private `buildNormal()` method:

```
private NotificationCompat.Builder buildNormal() {
  NotificationCompat.Builder b=
    new NotificationCompat.Builder(this, CHANNEL_WHATEVER);

  b.setAutoCancel(true)
   .setContentTitle(getString(R.string.download_complete))
   .setContentText(getString(R.string.fun))
   .setContentIntent(buildPendingIntent(Settings.ACTION_SECURITY_SETTINGS))
   .setSmallIcon(android.R.drawable.stat_sys_download_done)
   .setPriority(Notification.PRIORITY_HIGH)
   .addAction(android.R.drawable.ic_media_play,
              getString(R.string.play),
              buildPendingIntent(Settings.ACTION_SETTINGS));

  return(b);
}
```

(from Notifications/BigNotify/app/src/main/java/com/commonsware/android/bignotify/MainActivity.java)

Most of what `buildNormal()` does is the same sort of stuff we saw with `NotificationCompat.Builder` earlier in this chapter. There are two things, though, that are new:

1. We call `setPriority()` to set the priority of the `Notification` to `PRIORITY_HIGH`. This means that this `Notification` *may* be displayed higher in the notification shade than it might ordinarily appear.
2. We call `addAction()` to add an action button to the `Notification`, to be shown in the expanded form. We are able to supply an icon, caption, and

PendingIntent, the latter created by a buildPendingIntent() method that wraps our desired Intent action string (here, Settings.ACTION_SETTINGS) in an Intent:

```
private PendingIntent buildPendingIntent(String action) {
  Intent i=new Intent(action);

  return(PendingIntent.getActivity(this, 0, i, 0));
}
```

(from Notifications/BigNotify/app/src/main/java/com/commonsware/android/bignotify/MainActivity.java)

Ordinarily, we might use this Builder directly, to raise the Notification we described. And, if we just wanted the action button to appear and nothing else new in the expanded form, we could do just that. But in our case, we also want to change the look of the expanded widget to a new style, InboxStyle. To do that, we need to wrap our Builder in a NotificationCompat.InboxStyle builder:

```
@Override
public void onCreate(Bundle savedInstanceState) {
  super.onCreate(savedInstanceState);

  NotificationManager mgr=
      (NotificationManager)getSystemService(NOTIFICATION_SERVICE);

  if (Build.VERSION.SDK_INT>=Build.VERSION_CODES.O &&
    mgr.getNotificationChannel(CHANNEL_WHATEVER)==null) {
    mgr.createNotificationChannel(new NotificationChannel(CHANNEL_WHATEVER,
      "Whatever", NotificationManager.IMPORTANCE_DEFAULT));
  }

  NotificationCompat.Builder normal=buildNormal();
  NotificationCompat.InboxStyle big=
      new NotificationCompat.InboxStyle(normal);

  mgr.notify(NOTIFY_ID,
             big.setSummaryText(getString(R.string.summary))
                .addLine(getString(R.string.entry))
                .addLine(getString(R.string.another_entry))
                .addLine(getString(R.string.third_entry))
                .addLine(getString(R.string.yet_another_entry))
                .addLine(getString(R.string.low)).build());

  finish();
}
```

(from Notifications/BigNotify/app/src/main/java/com/commonsware/android/bignotify/MainActivity.java)

Each of these "big" builders has a set of methods that are unique to that type of builder to configure the look beyond what a standard `Notification` might have. Specifically, in this case, we call:

- `setSummaryText()`, to provide "the first line of text after the detail section in the big form of the template", in the words of the JavaDocs, though this does not necessarily mean what you think it does
- `addLine()`, to append several lines of text to appear in the `Notification`

It is the `Notification` created by our `NotificationCompat.InboxStyle` builder that we use with the call to `notify()` on `NotificationManager`.

The Results

If we run our app, we get this:

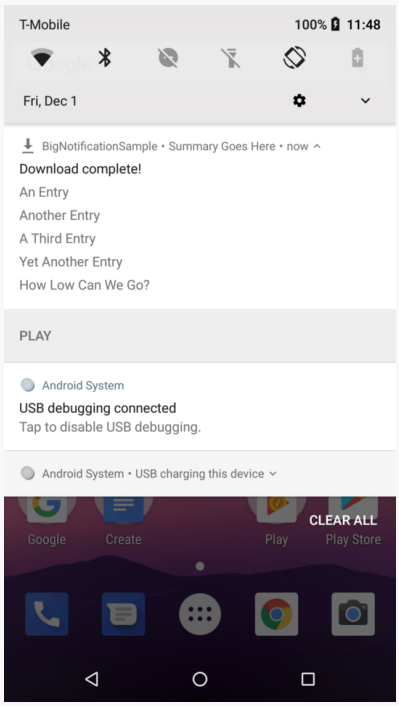

Figure 388: Expanded Notification in Shade, on Android 8.1

From top to bottom, we have:

- Our content text
- Our appended lines of text

- Our action button
- Our summary text

Note that this is the appearance when we are in expanded mode, at the top of the notification shade. If our `Notification` is not at the top, or if it is displayed on a pre-4.1 device, the appearance is the normal style, as defined by our `buildNormal()` method, though on Android 4.1+ devices the user can use a two-finger downward swipe gesture to expand the un-expanded `Notification`.

Foreground Services

If you have a service that will run for a substantial period of time, there is a risk that your process will still be terminated. That could be triggered by the user, or it could be the OS's own decision, based on the age of your process.

Generally speaking, this is a good thing for the user, because too many developers "leak" services, causing them to run unnecessarily, without adding value to the user, and tying up system RAM as a result.

But, what about services that *are* delivering value to the user for a long period? For example, what about a music player, where, in theory, the service is delivering value until the user presses some sort of "stop" button somewhere to turn off the music?

For those sorts of situations, you can flag a service as being a "foreground service".

Isn't "Foreground Service" an Oxymoron?

You might be forgiven for thinking that "foreground" and "service" are not designed to go together.

Partly, that is because we have overloaded the term "foreground".

A foreground service is *not* one that somehow takes over the screen. A foreground service *is* one that runs with foreground priority. That means:

- It will be treated similarly to the app that is in the UI foreground, from the standpoint of determining processes eligible for termination
- It will be classified as foreground from a CPU standpoint, rather than being relegated to the standard background process group

The former is what many developers want: a service (and process) that will not go away.

The latter is what many users fear: a service (and process) that is capable of stealing chunks of CPU time away from the game, video, or whatever else is truly in the foreground from a UI standpoint.

Services themselves, while useful, are best when used *sparingly*, only running when they are actively delivering value to the user. "This goes double" for foreground services.

Putting Your Service in the Foreground

Putting a service into the foreground is a matter of calling `startForeground()`. This method takes two parameters, the same two parameters that you would pass to `notify()` of `NotificationManager`:

- A prepared `Notification`
- A unique ID for that `Notification`

Android will then display the `Notification`. So long as the `Notification` is visible, your app's process will be given foreground priority.

You undo this by calling `stopForeground()`. `stopForeground()` takes a boolean parameter, indicating if the `Notification` should be removed (`true`) or not (`false`). Typically, you will pass `true`, so the `Notification` only clutters up the screen while you need it.

The `Notifications/Foreground` sample project is a clone of the `Notifications/DownloadNotify` sample that opened this chapter, adding in the use of `startForeground()` and `stopForeground()`.

Towards the top of `onHandleIntent()`, we call `startForeground()`, to *really* ensure that our process will remain intact long enough to complete the requested download:

```
    startForeground(FOREGROUND_ID,
      buildForegroundNotification(filename));
```

(from Notifications/Foreground/app/src/main/java/com/commonsware/android/foredown/Downloader.java)

This, in turn, uses a `buildForegroundNotification()` method to build the `Notification` that will be displayed while the service is categorized as being in the foreground:

```
private Notification buildForegroundNotification(String filename) {
  NotificationCompat.Builder b=
    new NotificationCompat.Builder(this, CHANNEL_WHATEVER);

  b.setOngoing(true)
   .setContentTitle(getString(R.string.downloading))
   .setContentText(filename)
   .setSmallIcon(android.R.drawable.stat_sys_download);

  return(b.build());
}
```

(from Notifications/Foreground/app/src/main/java/com/commonsware/android/foredown/Downloader.java)

Note that we use `setOngoing(true)`, to indicate that this is an "ongoing" operation. This precludes the user from removing the `Notification` manually, as doing that would drop our process out of foreground priority.

At the end of `onHandleIntent()`, we call `stopForeground()` in a `finally` block, to ensure that it gets called:

```
  try {
    // rest of code omitted for brevity

    raiseNotification(i, output, null);
  }
  catch (IOException e2) {
    raiseNotification(i, null, e2);
  }
  finally {
    stopForeground(true);
  }
```

We pass `true` to `stopForeground()` to remove the `Notification`. From the user's perspective, we could just as easily have passed `false`, as the `Notification` used with `startForeground()` will also be removed once our service is destroyed, which will happen shortly after `onHandleIntent()` ends.

If you want to update the foreground `Notification`, you can either:

- Call `notify()` again with the same notification ID and a fresh `Notification`, as you would use to update any `Notification`, or
- Simply call `startForeground()` again, with the same notification ID and a fresh `Notification`

We will see this particular practice in use later in the book, where we use a foreground service's `Notification` to control recording a screencast of an Android device.

The Malformed Notification

Of course, some developers do not play nicely with the other kids.

A technique that had been around for a while was for an app to pass an intentionally-flawed `Notification` to `startForeground()`. While Android would blow up silently somewhere internally actually trying to display the `Notification`, the foreground status was still granted. This resulted in behavior reminiscent of the long-since-deprecated `setForeground()` method.

`setForeground()` allowed a service to get foreground priority with no repercussions. Not surprisingly, lots of developers used it, as they decided that their app was more important than any other apps on the device. `setForeground()` was replaced by `startForeground()`, adding in the `Notification` requirement, to put a "cost" on foreground status. The malformed-`Notification` trick allowed developers to avoid that cost.

In Android 4.3, if you pass a malformed `Notification` to `startForeground()`, Android will create one for you, featuring your app's launcher icon, and use it instead. Hence, on Android 4.3 and higher, you cannot hide your foreground status from the user.

Disabled Notifications

Because apps have the ability to display larger-than-normal `Notifications`, plus force them towards the top of the list via priority levels, Android has given users the ability to disable `Notifications` on a per-app basis. The degree of control, and the way the user sets up that control, depends upon Android version.

Android 4.x

Users visiting an app's page in Settings will see a "Show notifications" checkbox:

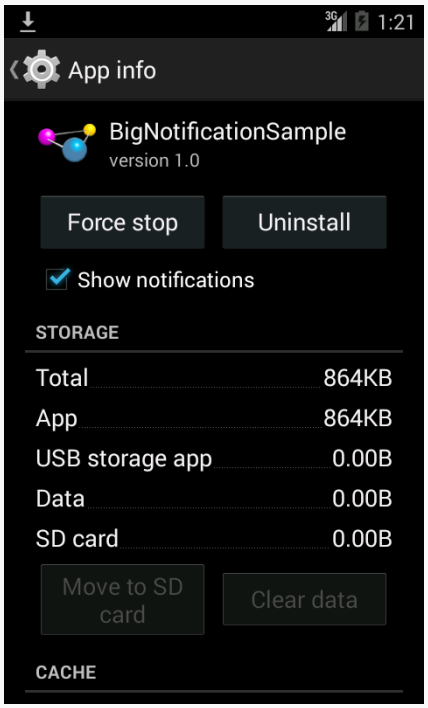

Figure 389: Show Notifications Checkbox, on Android 4.4

If the user unchecks the checkbox and agrees on the resulting confirmation dialog, your requests to raise a `Notification` will be largely ignored. An error message will appear in Logcat ("Suppressing notification from package ... by user request"), but no exception will be raised. Further, there does not appear to be an API for you to determine if the notification will actually be displayed.

Also note that, on Android 4.2+, if the user blocks notifications, it also blocks `Toast` requests from your app.

And, also note that this setting survives an uninstall of your app. If the user unchecks this checkbox, uninstalls your app, then reinstalls your app, the checkbox is still unchecked, meaning that notifications will still be blocked.

The one notable exception to this blocking, as of Android 4.3, is that the `Notification` associated with a foreground service will not be blocked. It will always appear, even if the user unchecked "Show notifications" for your app in Settings.

Android 5.0+

In the "Sound & notification" area of Settings, the user can tap on an "App notifications" option, and from there choose an app. This brings up a screen where the user can "block" (i.e., disable) notifications:

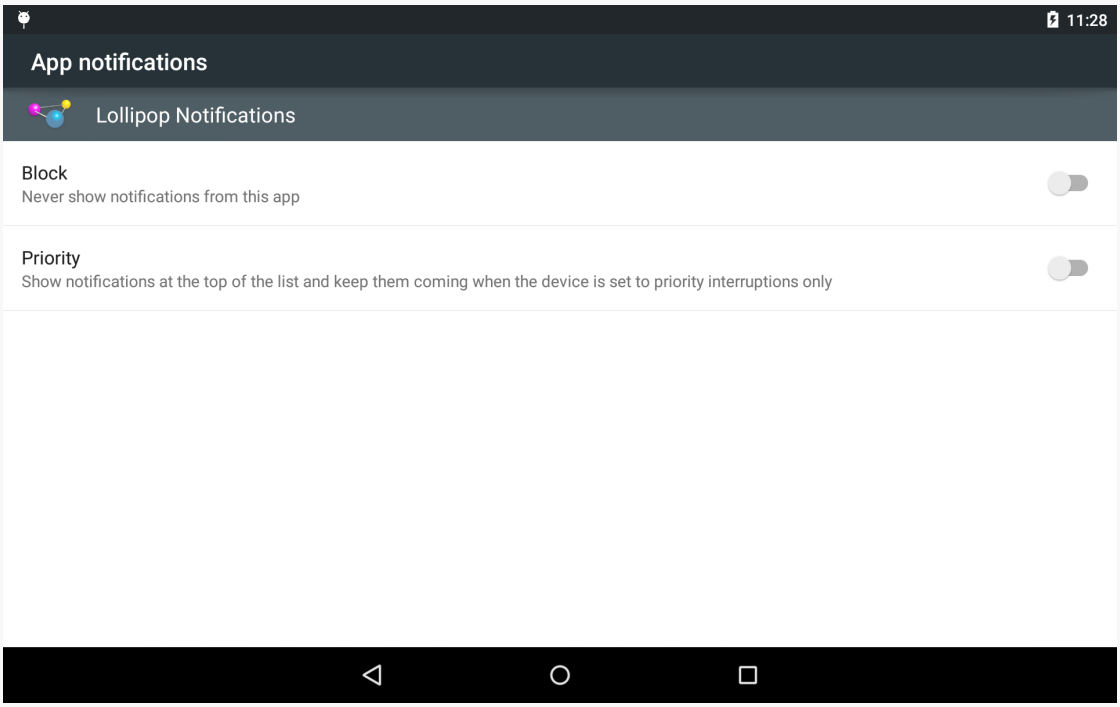

Figure 390: "App notifications" in Settings, on Android 5.0

The top "Block" `SwitchPreference`, if toggled on, will prevent app notifications from being displayed.

The bottom "Priority" `SwitchPreference`, if toggled on, marks this app's notifications as being "priority". Then, in the main "Sound & notification" area of Settings, the user can tap on an "Interruptions" option:

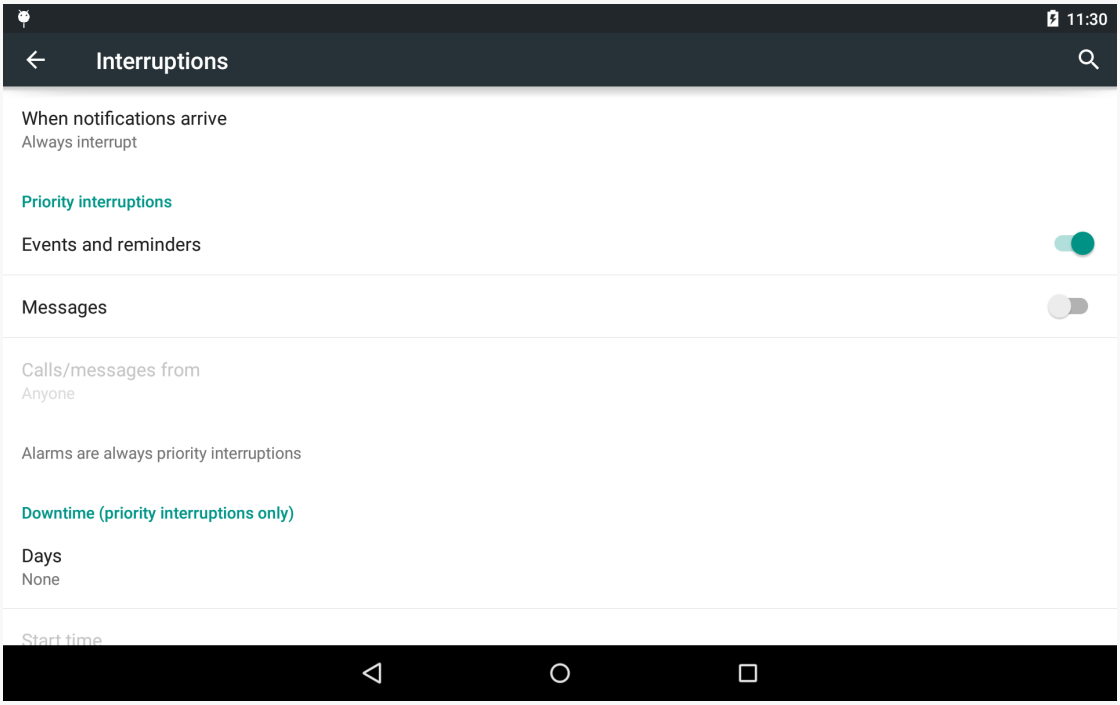

Figure 391: "Interruptions" in Settings, on Android 5.0

If the user toggles the "When notifications arrive" option to "Allow only priority interruptions", then those apps that the user configures as "Priority" in "App notifications" will behave normally. Other apps' notifications will appear, but will not play a ringtone or vibrate the device.

If the user toggles the "When notifications arrive" option to "Don't interrupt", all notifications — even those marked as "Priority" — will have their ringtones and vibrations suppressed.

Android 8.0+

Users have similar control capability on Android 8.0 and higher as they did on Android 5.0 through 7.1. Now, however, they are divided into channels, as will be explained in the chapter on advanced notifications.

Advanced Notifications

Notifications are those icons that appear in the status bar (or system bar on tablets), typically to alert the user of something that is going on in the background or has completed in the background. Many apps use them, to let the user know of new email messages, calendar reminders, and so on. Foreground services, such as music players, also use notifications, to tell the OS that they are part of the foreground user experience and to let the user rapidly return to the apps to turn the music off.

There are other tricks available with the `Notification` object beyond those originally discussed in an earlier chapter.

Prerequisites

Understanding this chapter requires that you have read the chapter on basic notifications and the section on `RemoteViews` in the chapter on basic app widgets.

Being a Good Citizen

Users have a love/hate relationship with apps that use notifications:

- They love apps that raise notifications for events that the user cares about...
- ...but they hate apps that raise notifications for events that the user does not care about (e.g., Evernote's "please confirm your email" notifications)
- They love apps that provide control over when and how notifications appear...
- ...but they hate apps that display notifications solely because the developer wanted them (e.g., ads in notifications)

- They love apps that use notifications to let the user control some background operation, like media playback...
- ...but they hate apps that have ongoing notifications for no obvious reason (e.g., developers trying to use a foreground service to keep their process around, rather than using `AlarmManager`, `JobScheduler`, or other means of doing work periodically)
- They love apps that set up notifications for use in different scenarios, such as supporting Android Wear devices...
- ...but they hate apps that wind up flooding their wrist (or eyes, or other wearable locations) with notifications that have to be individually dismissed

And so on.

Users' discomfort with how apps handle notifications is why Android allows users to disable notifications.

Some of the items in this chapter, particularly those surrounding Android Wear, can help you improve user satisfaction with your notification strategy and tactics. Yet, at the same time, misuse of notifications is magnified by Wear, as Wear takes extra steps to get the user to pay attention to the notifications, with possibly disastrous results for your Play Store reviews.

In short, your objective with notifications is to be a good citizen:

- Have a reasonable default mode for your notifications
- Allow users to tailor that mode to better suit their needs, where practical

More About Channels

Android 8.0 moved a lot of notification configuration out of `NotificationCompat.Builder` and into a new `NotificationChannel` class, and moving their effects from being per-notification to per-channel. When you configure a channel, all notifications in that channel will exhibit the behavior defined for the channel.

What You Do with Channels

Many configuration options formerly set on a `Notification` are now set on a `NotificationChannel`:

You Used to Call This on `Notification`	You Now Call This on `NotificationChannel`
`setDefaults()`	no real analogue
`setLights()`	`enableLights()` and `setLightColor()`
`setPriority()`	`setImportance()`
`setSound()`	`setSound()`
`setVibration()`	`enableVibration()` and `setVibrationPattern()`
`setVisibility()`	`setLockscreenVisibility()`

The "enable" methods (`enableLights()`, `enableVibration()`) opt you into whatever the device default behaviors are for those features.

As a result of these things moving to `NotificationChannel`, the user can control the behavior. You might *request* to enable vibration, but the user will be able to override your choice, for example.

In addition to these options, a `NotificationChannel` also configures:

- Whether this channel's notifications should bypass do-not-disturb settings (`setBypassDnd()`)
- Whether a launcher icon badge should be used with this channel's notifications (`setShowBadge()`)

Channels can also be associated into channel groups. This is purely for organizational purposes; groups show up on the screen that the user sees to help cluster related channels together. Beyond that, channels in groups behave identically to channels not in groups.

Creating Channel Groups

A `NotificationChannelGroup` is the Java class embodiment of a channel group. A `NotificationChannelGroup` consists purely of a `String` unique identifier and a `CharSequence` (e.g., `String`) display name to show the user. In most cases, you will want the display name to come from a string resource, for translation purposes.

You need to register your channel groups with Android. To do this, you will need to call one of the following methods on `NotificationManager`:

- `createNotificationChannelGroup()`, to create a single channel group

- `createNotificationChannelGroups()`, to create a `List` of channel groups

The Notifications/Channels sample project demonstrates the use of notification channels and channel groups. The `MainActivity` has an `initGroups()` method that defines two channel groups:

```
private void initGroups() {
  ArrayList<NotificationChannelGroup> groups=new ArrayList<>();

  groups.add(new NotificationChannelGroup(GROUP_UPDATES,
    getString(R.string.group_name_updates)));
  groups.add(new NotificationChannelGroup(GROUP_PROMO,
    getString(R.string.group_name_promo)));

  mgr.createNotificationChannelGroups(groups);
}
```

(from Notifications/Channels/app/src/main/java/com/commonsware/android/notify/channel/MainActivity.java)

Here, the display names come from string resources, and the channel group IDs are string constants defined on `MainActivity` itself.

Creating Channels

Creating channels, in turn, involves configuring `NotificationChannel` objects and calling `createNotificationChannel()` on `NotificationManager` for each channel.

`MainActivity` has three methods for defining three separate channels, in those two channel groups:

```
private void initContentChannel() {
  NotificationChannel channel=
    new NotificationChannel(CHANNEL_CONTENT,
      getString(R.string.channel_name_content),
      NotificationManager.IMPORTANCE_LOW);

  channel.setGroup(GROUP_UPDATES);
  mgr.createNotificationChannel(channel);
}

private void initBattleChannel() {
  NotificationChannel channel=
    new NotificationChannel(CHANNEL_BATTLE,
      getString(R.string.channel_name_battle),
      NotificationManager.IMPORTANCE_HIGH);
```

```
  channel.setGroup(GROUP_UPDATES);
  channel.setShowBadge(true);
  mgr.createNotificationChannel(channel);
}

private void initCoinsChannel() {
  NotificationChannel channel=
    new NotificationChannel(CHANNEL_COINS,
      getString(R.string.channel_name_coins),
      NotificationManager.IMPORTANCE_DEFAULT);

  channel.setGroup(GROUP_PROMO);
  mgr.createNotificationChannel(channel);
}
```

(from Notifications/Channels/app/src/main/java/com/commonsware/android/notify/channel/MainActivity.java)

The constructor takes a unique `String` identifier for the channel, a user-facing display name for the channel, and the importance of the notifications in that channel. Again, typically you will want to use a string resource for the display name, as the sample code demonstrates.

Between creating the `NotificationChannel` and registering it with `createNotificationChannel()` on `NotificationManager`, you can call various setter methods to configure the way that this channel behaves, beyond the importance. For example, if you are using channel groups, you will need to call `setGroup()` on the `NotificationChannel`, passing in the channel group ID.

All of these methods are invoked from `onCreate()` of `MainActivity`:

```
@Override
protected void onCreate(Bundle savedInstanceState) {
  super.onCreate(savedInstanceState);

  mgr=getSystemService(NotificationManager.class);

  if (mgr.getNotificationChannel(CHANNEL_CONTENT)==null) {
    initGroups();
    initContentChannel();
    initBattleChannel();
    initCoinsChannel();
  }

  setContentView(R.layout.activity_main);
}
```

(from Notifications/Channels/app/src/main/java/com/commonsware/android/notify/channel/MainActivity.java)

In particular, we only call those methods if we do not already have the `CHANNEL_CONTENT` channel defined, as determined via a call to `getNotificationChannel()` on `NotificationManager`. This `if` check serves two purposes:

1. We avoid running through a bunch of initialization code for things that we have already initialized
2. We cannot change notification channels or channel groups once we create them, as we will examine more later in this chapter

What the User Sees

When the user visits the notification settings for this app, all three channels appear, clustered into the two groups:

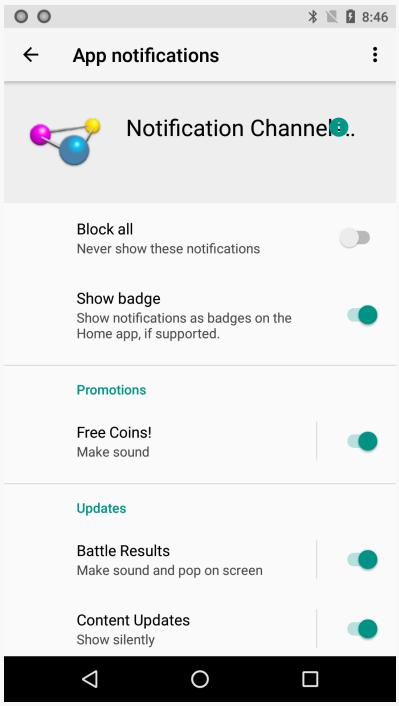

Figure 392: Notification Settings, Showing Three Channels in Two Groups

The groups appear to be sorted alphabetically, not in the order that they are defined.

Tapping on the channel itself brings up a screen for configuring the details of that channel:

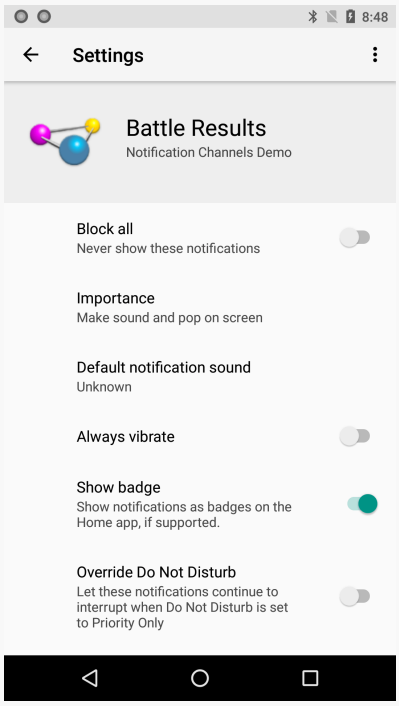

Figure 393: Notification Settings, Showing Channel Configuration

Of note, if the importance calls for a sound, and you did not supply a `Uri` to some ringtone via `setSound()` on the `NotificationChannel`, the user will see that the "Default notification sound" is "Unknown", though this really means that the default notification sound will be used.

You can bring up the activity for configuring channel settings yourself, via an `ACTION_CHANNEL_NOTIFICATION_SETTINGS` `Intent` and a call to `startActivity()`:

```
@Override
public boolean onOptionsItemSelected(MenuItem item) {
  if (item.getItemId()==R.id.settings) {
    Intent i=new Intent(Settings.ACTION_CHANNEL_NOTIFICATION_SETTINGS);

    i.putExtra(Settings.EXTRA_CHANNEL_ID, CHANNEL_BATTLE);
    i.putExtra(Settings.EXTRA_APP_PACKAGE, getPackageName());
    startActivity(i);
  }
```

```
    return super.onOptionsItemSelected(item);
  }
```

(from Notifications/Channels/app/src/main/java/com/commonsware/android/notify/channel/MainActivity.java)

This requires two extras:

- `EXTRA_APP_PACKAGE` is your application ID, returned via `getPackageName()` or `BuildConfig.APPLICATION_ID`
- `EXTRA_CHANNEL_ID` is the channel ID of the channel whose settings you wish to display

Once and Done

Once you create a notification channel, control over the channel settings resides with the user. You cannot modify the settings of that channel. Consider your settings to be defaults; the user is welcome to modify the channel from those defaults as the user sees fit.

To help prevent developers from deleting and re-creating channels, while you can call `deleteNotificationChannel()` on `NotificationManager`, that channel will still be visible to the user ("Deleted channels remain visible in notification settings, as a spam prevention mechanism.")

Backwards Compatibility

There is no backport of notification channels.

`NotificationCompat.Builder` takes a channel ID, but you will need to use the native `NotificationChannel` class to define the channel. And since that class only exists on Android 8.0+, unless your `minSdkVersion` is 26 or higher, you will need to make sure that you use `NotificationChannel` only on suitable devices, using the recipe that we saw in the original chapter on notifications:

```
if (Build.VERSION.SDK_INT>=Build.VERSION_CODES.O &&
  mgr.getNotificationChannel(CHANNEL_WHATEVER)==null) {
  mgr.createNotificationChannel(new NotificationChannel(CHANNEL_WHATEVER,
    "Whatever", NotificationManager.IMPORTANCE_DEFAULT));
}
```

Wear? There!

The humble `Notification` has been steadily advancing over the past few years, with "big" styles and the like adding new capabilities for newer devices.

Android Wear takes notifications to a new level, by having the notification not only appear on the user's device, but also on wearables connected to that device.

The good news is that this works "out of the box". There is nothing you absolutely need to do in your app to get your notifications to appear on a Wear device.

The bad news is that the "out of the box" experience may be poor, as a `Notification` approach that is fine for devices that reside in pockets and backpacks might be inappropriate for wrists and eyes.

With that in mind, let's see what some notification samples from earlier in the book behave like when they are run on a phone connected to a Wear device.

NOTE: For this section, and the rest of this chapter, "primary device" will refer to the user's phone or tablet that the "Wear device" will be connected to.

Simple Notification

The `Notifications/DownloadNotify` sample project allows the user to download a PDF file, raising a `Notification` when that download is complete.

With a Wear device paired with the phone, the `Notification` also appears on the device, first as a "mini card":

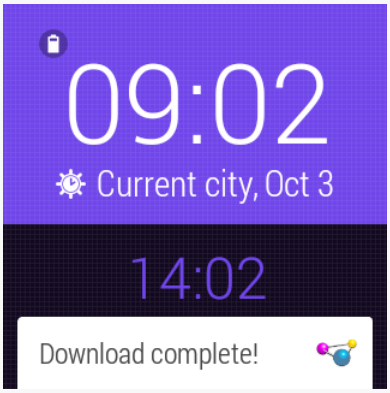

Figure 394: Simple Notification on Wear, As Originally Displayed, On Samsung Galaxy Gear

Swiping up on that will bring up the full card:

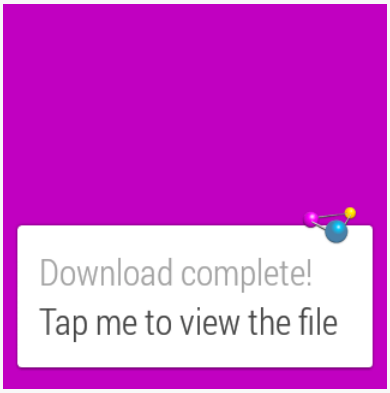

Figure 395: Simple Notification on Wear, Full, On Samsung Galaxy Gear

Swiping to the right will bring up the action associated with `setContentIntent()` on the `NotificationCompat.Builder`:

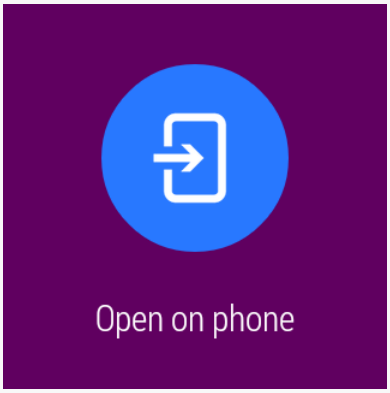

Figure 396: Simple Notification on Wear, Default Action, On Samsung Galaxy Gear

Tapping on that dismisses the `Notification` on the Wear device and the primary device, plus it invokes the `PendingIntent` on the phone itself (in this case, opening up the PDF file).

This is a fine example of a `Notification` that perhaps should *not* appear on the Wear device. The fact that the download completed is interesting but not all that important. Furthermore, the user cannot do anything about this download other than to pull out the primary device to see the PDF. Low-priority primary-device-centric notifications generally should be shown on the primary device alone, not on the Wear device. We will see how to do that later in this chapter.

"Big" Style and Action Button

The `Notifications/BigNotify` sample application wrapped a regular `Notification` in a `NotificationCompat.InboxStyle` "big" `Notification`, one with both a regular action and a separate "Play" action button.

As before, with a Wear device paired with the phone, the `Notification` also appears on the device, first as a "mini card":

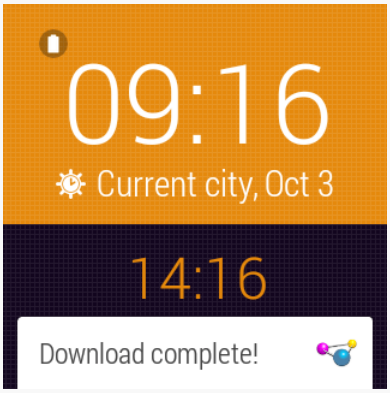

Figure 397: Big Notification on Wear, As Originally Displayed, On Samsung Galaxy Gear

However, this time, when the user swipes up to show the full card, it is the `InboxStyle` version that appears, albeit without the summary text:

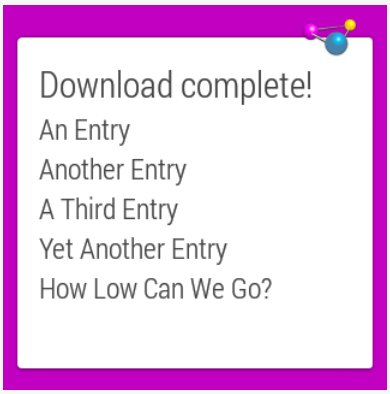

Figure 398: Big Notification on Wear, Full, On Samsung Galaxy Gear

Swiping to the right shows our actions, starting with the custom “Play” action:

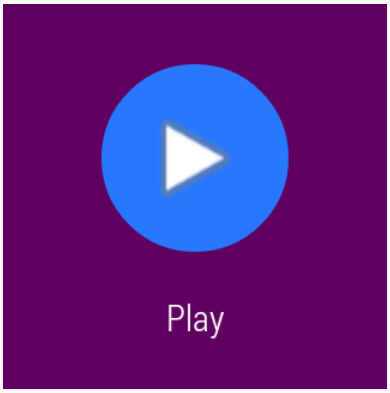

Figure 399: Big Notification on Wear, Play Action, On Samsung Galaxy Gear

...followed by the default action:

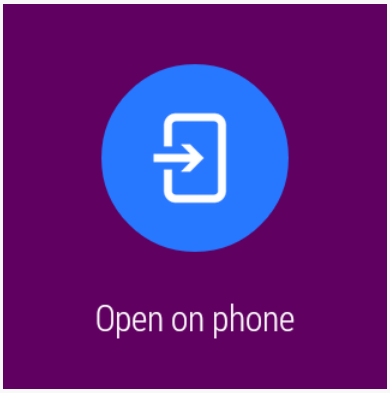

Figure 400: Big Notification on Wear, Default Action, On Samsung Galaxy Gear

Tapping on either action will cause the primary device to invoke its `PendingIntent`, but only the default action dismisses the `Notification` from both devices. The custom "Play" action does not.

Foreground Service

The `Notifications/Foreground` sample project is another version of the download-the-file sample, but this time uses a `Notification` and `startForeground()` to mark the service as a foreground service while it is downloading things.

This particular sample does not spend much time in the foreground state, so for testing purposes, you may want to add a `SystemClock.sleep()` call to the service,

between the `startForeground()` and `stopForeground()` calls, to better examine the behavior while the foreground service `Notification` is around.

However, in truth, that modification is probably not necessary... as the foreground service `Notification` is not displayed on the Wear device, only on the primary device. This is by design. The expectation is that you would use a Wear app to control your service from the Wear device, not some un-dismissable card.

Stacking Notifications

If you are writing an email client, and you want to use a `Notification` to let the user know about new email messages, you do *not* want to raise a separate `Notification` for each email. Users will come to your home with pitchforks and torches... and not to help you with farming.

Instead, the vision is that you update an existing `Notification` with new content. For example, you might start with a regular `Notification` for the first received email. Then, when the second one comes in, you replace that `Notification` with one that has a simple summary ("2 messages are in your inbox!"), plus perhaps an `InboxStyle` "big" `Notification` variant that could show the subject lines for both of those messages.

Android Wear devices, however, add an interesting wrinkle: you want the `Notification` to be informative about the event itself. You want the user to be able to make an informed decision about whether they should pull out their primary device to read the new messages, and that decision is only partly based on how many messages there are. Users will want to know more about the outstanding messages (sender and/or subject line) to help them make that decision... at least to a point. If there are 57 unread messages, users may get frustrated dealing with all of those as individual items on the wearable itself.

The pattern here, then, takes advantage of some "group" capabilities added to `NotificationCompat`:

- Raise one "summary" `Notification`, that will only be shown on the primary device, with the same sort of "2 messages are in your inbox!" information that you would have used without considering Wear
- Raise individual notifications for individual messages that will appear on the Wear device

- Collect all of those in a "group", so the primary device shows only the summary and the Wear device shows only the individual ones

This can be seen in action in the `Notifications/Stacked` sample project.

The setup is reminiscent of the "big" style one from the original chapter on `Notification`. However, this time, there are a total of three `Notification` objects created: two for individual events for the Wear device, and one summary one for the primary device.

However, to make this work, we need a new version of the `support-v13` library from the Android Support package: `20.0.0` (or higher), as it is where the extra compatibility smarts were added to support this whole group-and-summary construct. Hence, in `build.gradle`, we have `implementation 'com.android.support:support-v13:20.0.0'`.

Similarly, while we will still use `NotificationCompat` for creating the `Notification` objects, we will *not* use `NotificationManager` for displaying them. Instead, we need to use `NotificationManagerCompat` from the Android Support package. While the `NotificationManager` API has not changed to support the group-and-summary pattern, the *implementation* has, and `NotificationManagerCompat` gives us a version of that implementation that can work on compatible devices and gracefully degrade on older ones. However, since the API did not change, it is easy to miss this requirement, use `NotificationManager`, and not quite get the desired results. Notably, the primary device will wind up showing all three notifications, not just the summary as we want.

Hence, our `MainActivity` will hold onto a `NotificationManagerCompat` as a data member, initialized in `onCreate()`:

```
private NotificationManagerCompat mgrCompat=null;

@Override
public void onCreate(Bundle savedInstanceState) {
  super.onCreate(savedInstanceState);

  NotificationManager mgr=
    (NotificationManager)getSystemService(NOTIFICATION_SERVICE);

  if (Build.VERSION.SDK_INT>=Build.VERSION_CODES.O &&
    mgr.getNotificationChannel(CHANNEL_WHATEVER)==null) {
    mgr.createNotificationChannel(new NotificationChannel(CHANNEL_WHATEVER,
      "Whatever", NotificationManager.IMPORTANCE_DEFAULT));
```

```
    }

    mgrCompat=NotificationManagerCompat.from(this);

    showWearOne();
    showWearTwo();
    showSummary();

    finish();
  }
```

(from Notifications/Stacked/app/src/main/java/com/commonsware/android/stacked/MainActivity.java)

The three `show...()` methods are each responsible for raising one `Notification`: `showWearOne()` and `showWearTwo()` are ones that will wind up on the Wear device, and `showSummary()` will show the summary `Notification` for use on the primary device.

Beyond using `NotificationManagerCompat` instead of `NotificationManager`, the only substantial difference is the use of `setGroup()` and `setGroupSummary()` methods on the `NotificationCompat.Builder`.

`setGroup()` associates the `Notification` with a group, identified by a `String` key. On a Wear device, notifications that are part of a group will be shown stacked as part of a single card by default. So, the two `showWear...()` methods call `setGroup()` as part of building the `Notification`:

```
private void showWearOne() {
  NotificationCompat.Builder b=
    new NotificationCompat.Builder(this, CHANNEL_WHATEVER);

  b.setAutoCancel(true)
      .setDefaults(Notification.DEFAULT_ALL)
      .setContentTitle(getString(R.string.entry))
      .setContentIntent(buildPendingIntent(Settings.ACTION_SECURITY_SETTINGS))
      .setSmallIcon(android.R.drawable.stat_sys_download_done)
      .setGroup(GROUP_SAMPLE);

  mgrCompat.notify(NOTIFY_ID2, b.build());
}

private void showWearTwo() {
  NotificationCompat.Builder b=
    new NotificationCompat.Builder(this, CHANNEL_WHATEVER);

  b.setAutoCancel(true)
      .setDefaults(Notification.DEFAULT_ALL)
      .setContentTitle(getString(R.string.another_entry))
      .setContentIntent(buildPendingIntent(Settings.ACTION_SECURITY_SETTINGS))
      .setSmallIcon(android.R.drawable.stat_sys_download_done)
      .setGroup(GROUP_SAMPLE);
```

```
    mgrCompat.notify(NOTIFY_ID3, b.build());
  }
```

(from Notifications/Stacked/app/src/main/java/com/commonsware/android/stacked/MainActivity.java)

`setGroupSummary()` indicates a particular `Notification` that should serve as the summary for its group. This `Notification` will not be passed to the Wear device, and it replaces all other notifications for this group on the primary device. Hence, `showSummary()` (or, more accurately, the `buildNormal()` method that creates the base `Notification` for the summary) uses `setGroupSummary()`:

```
  private void showSummary() {
    NotificationCompat.Builder normal=buildNormal();
    NotificationCompat.InboxStyle big=
        new NotificationCompat.InboxStyle();

    big.setSummaryText(getString(R.string.summary))
        .addLine(getString(R.string.entry))
        .addLine(getString(R.string.another_entry));

    mgrCompat.notify(NOTIFY_ID, normal.setStyle(big).build());
  }

  private NotificationCompat.Builder buildNormal() {
    NotificationCompat.Builder b=
      new NotificationCompat.Builder(this, CHANNEL_WHATEVER);

    b.setAutoCancel(true)
        .setDefaults(Notification.DEFAULT_ALL)
        .setContentTitle(getString(R.string.download_complete))
        .setContentText(getString(R.string.fun))
        .setContentIntent(buildPendingIntent(Settings.ACTION_SECURITY_SETTINGS))
        .setSmallIcon(android.R.drawable.stat_sys_download_done)
        .setGroup(GROUP_SAMPLE)
        .setGroupSummary(true);

    return(b);
  }
```

(from Notifications/Stacked/app/src/main/java/com/commonsware/android/stacked/MainActivity.java)

Note that you need to use `setGroupSummary()` on a `NotificationCompat.Builder` on which you have also called `setGroup()`, to identify the group for which this `Notification` is a summary.

When you run this, the primary device shows the summary `Notification`:

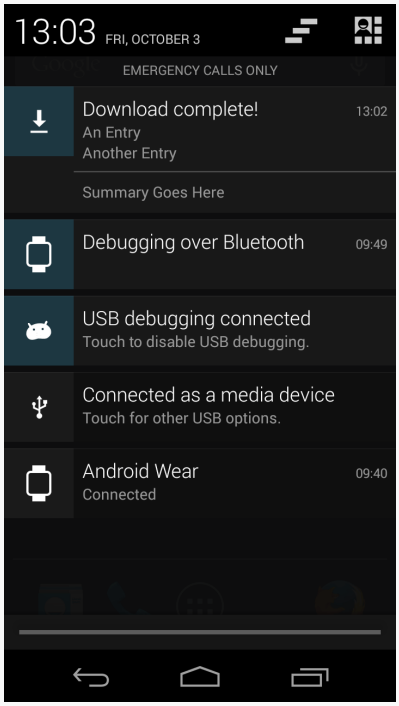

Figure 401: Stacked Notifications, Summary on Primary Device

On the Wear device, you will see the two original notifications as part of a single card at the outset:

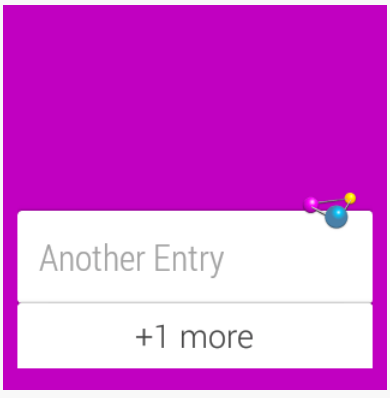

Figure 402: Stacked Notifications, Stacked on Wear Device

Tapping on the stack brings up separate mini cards for each individual `Notification`:

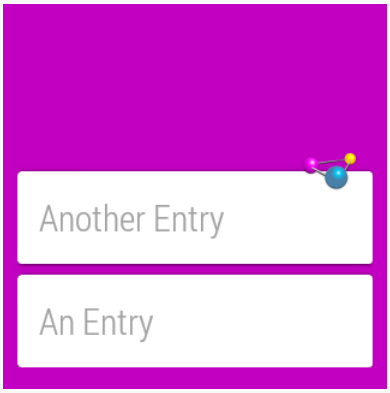

Figure 403: Stacked Notifications, Expanded Stack on Wear Device

…And the Passage of Time

Of course, this sample is artificially simple, like most of the samples in this book.

In the sample, we are raising all three notifications all at once. That is certainly conceivable, but it is not especially likely. A more likely scenario is that the mix of notifications needs to change over time, based upon continuing events, such as a trickle of new unread email messages for an email client.

This adds a few complexities to what you need to implement all of this properly.

The big thing is that your persistent data model (e.g., database) needs to have enough information for you to know how to notify the user about the next event, when that event occurs. Using the email client as an example:

- We start off in the "steady state" of no unread email messages and, therefore, no notifications from our app.
- A new email message arrives. At this point, we want to show a regular `Notification` on both the Wear device and the primary device, with the sender and subject line of the unread message.
- A second new email message arrives later. At this point, we want to show another regular `Notification` (requiring a separate notification ID) for the Wear device, but also show a summary `Notification` for the primary device. For all that to work, we need to know this *is* a second unread message, and that the user has not read the first message in between the two incoming messages. And, we need to know enough details about the unread messages to format the summary properly.

This gets even more complex when events "stack themselves" (e.g., one poll of the mail server results in two unread messages), in addition to having to deal with user input (e.g., user clears the notification stack from either device, yet does not read the messages).

Among other things, you cannot rely upon static data members as being the sole source of your `Notification`-related data, as your process may be terminated in between events. You are welcome to use it as a cache, in case your process does happen to survive long enough to process more than one event, but you will need to also save this data to a persistent store, so that you can properly handle new events requiring `Notification` changes with your process having been terminated since the last `Notification`-related event.

Avoiding Wear

Sometimes, you will want to raise a `Notification` that does not make sense to show on a Wear device, only on the primary device. In the case of the group summary for the stacked notifications, this primary-only behavior happens automatically. In other cases, though, you will need to call `setLocalOnly()` on the `NotificationCompat.Builder` to tell the framework that this `Notification` should only be displayed on the current device.

The Notifications/BigLocal sample project demonstrates this, through a clone of the `Notifications/BigNotify` sample that calls `setLocalOnly(true)` as part of configuring the `Notification`:

```
private NotificationCompat.Builder buildNormal() {
  NotificationCompat.Builder b=
    new NotificationCompat.Builder(this, CHANNEL_WHATEVER);

  b.setAutoCancel(true)
   .setDefaults(Notification.DEFAULT_ALL)
   .setContentTitle(getString(R.string.download_complete))
   .setContentText(getString(R.string.fun))
   .setContentIntent(buildPendingIntent(Settings.ACTION_SECURITY_SETTINGS))
   .setSmallIcon(android.R.drawable.stat_sys_download_done)
   .setTicker(getString(R.string.download_complete))
   .setPriority(NotificationCompat.PRIORITY_DEFAULT)
   .setLocalOnly(true)
   .addAction(android.R.drawable.ic_media_play,
       getString(R.string.play),
       buildPendingIntent(Settings.ACTION_SETTINGS));
```

```
    return(b);
  }
```

(from Notifications/BigLocal/app/src/main/java/com/commonsware/android/biglocal/MainActivity.java)

Note that we do not need to use `NotificationManagerCompat` for local-only behavior — simply calling `setLocalOnly(true)` on an up-to-date `NotificationCompat.Builder` will suffice.

Running this sample provides the same behavior as `Notifications/BigNotify`, except that the `Notification` only appears on the primary device, not the Wear device.

Other Wear-Specific Notification Options

Configuring stacked notifications, and opting into local-only behavior when needed, should give you Wear behavior that is acceptable. Right now, Android Wear is fairly nascent, and therefore it may not behoove you to do much more than this, as you decide how to prioritize your engineering time.

However, there are other things that you can do to further tailor your notifications on Wear that can improve user satisfaction, if you wish for Wear to be a key part of your marketing message.

Pages

On the primary device, the amount of information you can provide in a `Notification` is intentionally capped. This prevents a `Notification` from drowning out its peers. The cap is not a big problem, simply because the whole UI for the app raising the `Notification` is usually just a tap away.

With a Wear device, though, the whole UI for the app raising the `Notification` involves pulling out the primary device.

Hence, it might be nice to provide some additional information to the Wear user, so that perhaps they can make a more informed decision as to whether it is worthwhile to open up their primary device. In Wear terms, this involves adding more “pages” to a `Notification`.

To do this, you must:

- Create the second (and additional) pages as their own separate `Notification` objects, probably via a `NotificationCompat.Builder`
- Use a `NotificationCompat.WearableExtender` to teach the primary `Notification` about the additional pages
- Raise the primary `Notification` using a `NotificationManagerCompat` variant of the system service

We can see this in action in the [Notifications/Pages] sample project. This is a clone of `Notifications/BigNotify`, where we make the "big" content be on a second page.

```
@Override
public void onCreate(Bundle savedInstanceState) {
  super.onCreate(savedInstanceState);

  NotificationManager mgr=
    (NotificationManager)getSystemService(NOTIFICATION_SERVICE);

  if (Build.VERSION.SDK_INT>=Build.VERSION_CODES.O &&
    mgr.getNotificationChannel(CHANNEL_WHATEVER)==null) {
    mgr.createNotificationChannel(new NotificationChannel(CHANNEL_WHATEVER,
      "Whatever", NotificationManager.IMPORTANCE_DEFAULT));
  }

  NotificationManagerCompat mgrCompat=
      NotificationManagerCompat.from(this);
  NotificationCompat.Builder normal=buildNormal();
  NotificationCompat.InboxStyle big=
      new NotificationCompat.InboxStyle();

  big.setSummaryText(getString(R.string.summary))
      .addLine(getString(R.string.entry))
      .addLine(getString(R.string.another_entry))
      .addLine(getString(R.string.third_entry))
      .addLine(getString(R.string.yet_another_entry))
      .addLine(getString(R.string.low));

  NotificationCompat.Builder bigPage=
      new NotificationCompat.Builder(this, CHANNEL_WHATEVER)
          .setStyle(big);
  NotificationCompat.Builder twoPages=
      new NotificationCompat.WearableExtender()
          .addPage(bigPage.build())
          .extend(normal);

  mgrCompat.notify(NOTIFY_ID, twoPages.build());
```

```
    finish();
  }
```

(from Notifications/Pages/app/src/main/java/com/commonsware/android/pages/MainActivity.java)

Here, we:

- Create a `NotificationManagerCompat` instance
- Create the primary ("normal") `Notification`, using the same process as before
- Create the `InboxStyle` structure with our expanded content
- Wrap that "big" style in another `Notification` via a `NotificationCompat.Builder`, using the `setStyle()` method to associate the "big" style with the `Notification`
- Create a `NotificationCompat.WearableExtender`, tell it to add the second page using `addPage()`, and tell it to apply that second page to the primary `Notification` via the `extend()` method
- Use `notify()` as normal to raise the `Notification`, using the already-created `NotificationManagerCompat` instance

On the primary device, we just see the primary `Notification` content:

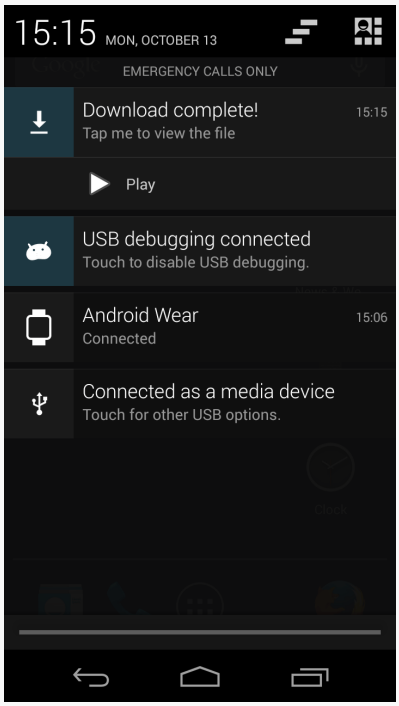

Figure 404: Pages Demo, on a Galaxy Nexus

On the Wear device, we see the main `Notification` and the second page as separate pages on the wearable:

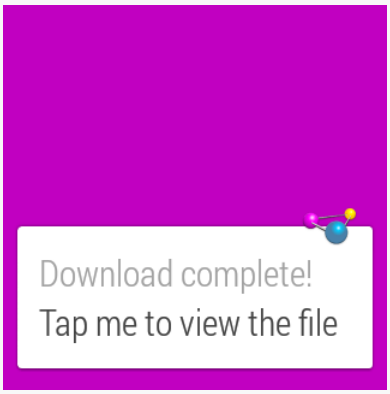

Figure 405: Pages Demo, on a Samsung Galaxy Wear, Showing Initial Notification

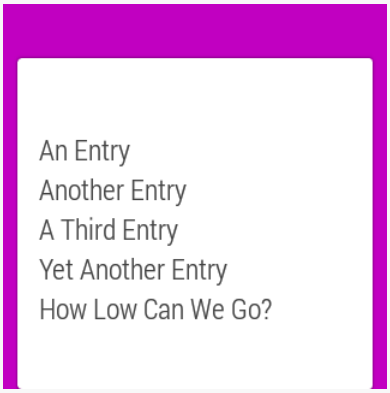

Figure 406: Pages Demo, on a Samsung Galaxy Wear, Showing Second Page

Note that you cannot use `addAction()` to define a custom action on the extra pages added to the primary `Notification`. Instead, use `addAction()` and `setContentAction()` on the `WearableExtender` to define actions associated with those extra pages. We will see this in use in the next section.

Wear-Only Actions

Sometimes, you may want certain actions to only be available on the Wear device, and not on the primary device. We will see a specific example of this coming up in the next section, when we cover voice input actions.

Sometimes, you may want a different mix of actions on the primary device versus the Wear device — some in common, some only on the primary device, some only on the Wear device.

To set up Wear-only actions, use `addAction()` on `WearableExtender`, as opposed to (or in addition to) `addAction()` on `NotificationCompat.Builder`. This takes an action as a parameter, which you create using `NotificationCompat.Action.Builder`, a custom builder for building `Notification` actions.

This is illustrated in the `Notifications/WearActions` sample project, yet another variation on the "launch an activity, show a `Notification`" samples that we have been using. This time, though, we will apply an action to the Wear device:

```
@Override
public void onCreate(Bundle savedInstanceState) {
  super.onCreate(savedInstanceState);

  NotificationManager mgr=
    (NotificationManager)getSystemService(NOTIFICATION_SERVICE);

  if (Build.VERSION.SDK_INT>=Build.VERSION_CODES.O &&
    mgr.getNotificationChannel(CHANNEL_WHATEVER)==null) {
    mgr.createNotificationChannel(new NotificationChannel(CHANNEL_WHATEVER,
      "Whatever", NotificationManager.IMPORTANCE_DEFAULT));
  }

  NotificationCompat.Builder normal=buildNormal();
  NotificationCompat.Action.Builder wearActionBuilder=
      new NotificationCompat.Action.Builder(android.R.drawable.ic_media_pause,
                                            getString(R.string.pause),
                                            buildPendingIntent(Settings.ACTION_DATE_SETTINGS));

  NotificationCompat.Builder extended=
      new NotificationCompat.WearableExtender()
          .addAction(wearActionBuilder.build())
          .extend(normal);

  NotificationManagerCompat.from(this).notify(NOTIFY_ID, extended.build());

  finish();
}
```

(from Notifications/WearActions/app/src/main/java/com/commonsware/android/wearactions/MainActivity.java)

Here, we:

- Create a `NotificationManagerCompat` instance
- Create the primary ("normal") `Notification`, using the same process as before
- Create an instance of `NotificationCompat.Action.Builder`, providing it the icon, label, and `PendingIntent` to be invoked for this action

- Create an instance of `NotificationCompat.WearableExtender`, adding the newly-defined action to it, and using the `WearableExtender` to `extend()` the primary `Notification`
- Show that extended `Notification` using the `NotificationManagerCompat` instance

However, note that we have also defined an action on the primary `Notification`:

```
private NotificationCompat.Builder buildNormal() {
  NotificationCompat.Builder b=
    new NotificationCompat.Builder(this, CHANNEL_WHATEVER);

  b.setAutoCancel(true)
   .setDefaults(Notification.DEFAULT_ALL)
   .setContentTitle(getString(R.string.download_complete))
   .setContentText(getString(R.string.fun))
   .setContentIntent(buildPendingIntent(Settings.ACTION_SECURITY_SETTINGS))
   .setSmallIcon(android.R.drawable.stat_sys_download_done)
   .addAction(android.R.drawable.ic_media_play,
      getString(R.string.play),
      buildPendingIntent(Settings.ACTION_SETTINGS));

  return(b);
}
```

(from Notifications/WearActions/app/src/main/java/com/commonsware/android/wearactions/MainActivity.java)

`addAction()` on `WearableExtender` *replaces*, for the Wear device, any actions defined on the `Notification` itself using `addAction()`, but not the action defined via `setContentIntent()`.

On the primary device, we do not see the wear-only action:

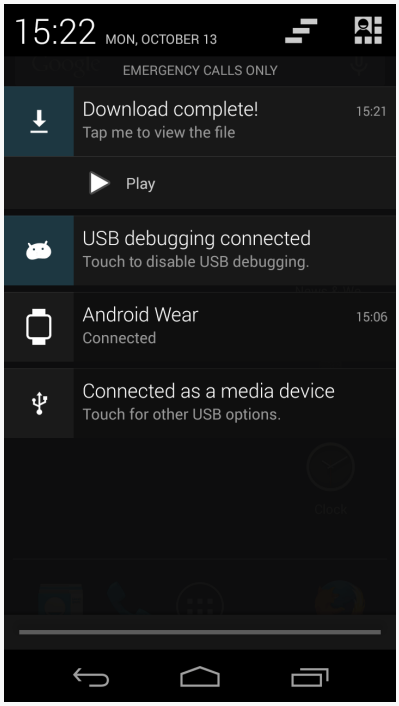

Figure 407: WearActions Demo, on a Galaxy Nexus

On a Wear device, though, we see both the wear-only and the main content action, but not the device-only action added via `addAction()` on the `NotificationCompat.Builder`:

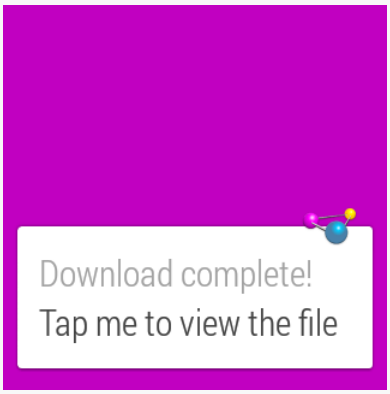

Figure 408: WearActions Demo, on a Samsung Galaxy Wear, Showing Notification

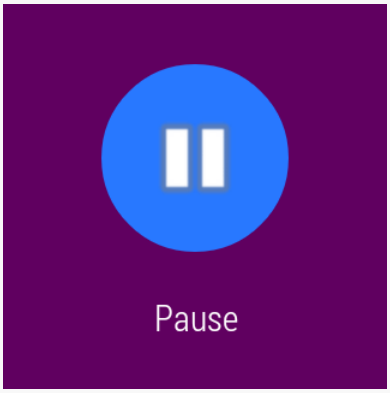

Figure 409: WearActions Demo, on a Samsung Galaxy Wear, Showing Wear-Only Action

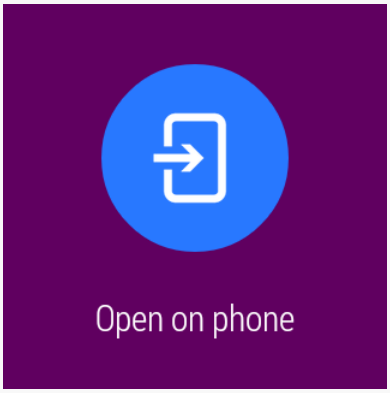

Figure 410: WearActions Demo, on a Samsung Galaxy Wear, Showing Main Content Action

Hence:

- If you want actions only on the primary device, define those before applying a `WearableExtender` and its `addAction()`
- If you want actions only on the Wear device, define those using a `WearableExtender` and its `addAction()`
- If you want the same actions on both devices, define those using both flavors of `addAction()` (on `NotificationCompat.Builder` for the primary device and on `WearableExtender` for the Wear device)

Voice Input

In the spirit of Dick Tracy's two-way wrist radio, Android Wear allows you to talk to your wrist and not seem like you are completely insane.

In particular, your `Notification`, when presented on the Wear, can request that the user provide you with a response, via voice input or via canned responses. This can be very handy:

- Responding to a text message without pulling out one's phone
- Directing your app to file an incoming email message into a particular folder or label
- Responding to a police alert, requesting your assistance, by indicating that you will be on your way as soon as you can find your bright yellow trenchcoat
- And so on

In many cases, with a regular `Notification`, the result of the user choosing an action is for us to display an activity. Sometimes, though, that's not what we want, such as a music player's `Notification` handling "pause" and similar events via its background service. Similarly, actions from a `Notification` seen on a Wear device will sometimes need to perform operations in the background, as the user may not be in position to look at your UI. This is especially true with voice input — usually, if we are bothering to dictate words to our wrist, that should happen instead of opening up the primary device. As a result, our flow for responding to the action is a little bit different, as is illustrated in the `Notifications/VoiceInput` sample project.

The Activity and Notification

Let's walk through the `MainActivity` that sets up our `Notification`:

```
package com.commonsware.android.wearvoice;

import android.app.Activity;
import android.app.NotificationChannel;
import android.app.NotificationManager;
import android.app.PendingIntent;
import android.content.Intent;
import android.os.Build;
import android.os.Bundle;
import android.support.v4.app.NotificationCompat;
import android.support.v4.app.NotificationManagerCompat;
```

```
import android.support.v4.app.RemoteInput;

public class MainActivity extends Activity {
  private static final String CHANNEL_WHATEVER="channel_whatever";
  private static final int NOTIFY_ID=1337;

  @Override
  public void onCreate(Bundle savedInstanceState) {
    super.onCreate(savedInstanceState);

    NotificationManager mgr=
      (NotificationManager)getSystemService(NOTIFICATION_SERVICE);

    if (Build.VERSION.SDK_INT>=Build.VERSION_CODES.O &&
      mgr.getNotificationChannel(CHANNEL_WHATEVER)==null) {
      mgr.createNotificationChannel(new NotificationChannel(CHANNEL_WHATEVER,
        "Whatever", NotificationManager.IMPORTANCE_DEFAULT));
    }

    Intent i=new Intent(this, VoiceReceiver.class);
    PendingIntent pi=
        PendingIntent.getBroadcast(this, 0, i,
            PendingIntent.FLAG_UPDATE_CURRENT);

    RemoteInput remoteInput=
        new RemoteInput.Builder(VoiceReceiver.EXTRA_SPEECH)
          .setLabel(getString(R.string.talk))
          .setChoices(getResources().getStringArray(R.array.replies))
          .build();

    NotificationCompat.Action wearAction=
        new NotificationCompat.Action.Builder(
              android.R.drawable.ic_btn_speak_now,
              getString(R.string.talk),
              pi).addRemoteInput(remoteInput).build();

    NotificationCompat.WearableExtender wearExtender=
        new NotificationCompat.WearableExtender()
            .addAction(wearAction);

    NotificationCompat.Builder builder=
        new NotificationCompat.Builder(this, CHANNEL_WHATEVER)
            .setSmallIcon(android.R.drawable.stat_sys_download_done)
            .setContentTitle(getString(R.string.title))
            .setContentText(getString(R.string.talk))
            .extend(wearExtender);

    NotificationManagerCompat
```

```
      .from(this)
      .notify(NOTIFY_ID, builder.build());

    finish();
  }
}
```

(from Notifications/VoiceInput/app/src/main/java/com/commonsware/android/wearvoice/MainActivity.java)

We start by creating a broadcast `PendingIntent`, pointing to a `VoiceReceiver` that will respond to the voice input. We will examine this `VoiceReceiver` later in this example.

We then set up a `RemoteInput.Builder`. This is a builder-style API for defining a `RemoteInput` configuration to attach to a Wear-only action. Here, we configure it with:

- the key for retrieving the response in our `VoiceReceiver` (`VoiceReceiver.EXTRA_SPEECH`)
- the label to prompt the user for what we are looking for them to provide (an `R.string.talk` string resource)
- a `String` array of canned responses that the user can choose from rather than dictate their own answer and go through speech-to-text conversion (pulled from an `R.array.replies` `<string-array>` resource)

That `RemoteInput` is then applied to a `NotificationCompat.Action`, via its `NotificationCompat.Action.Builder` and the `addRemoteInput()` method. That `Action`, in turn, is wrapped in a `NotificationCompat.WearableExtender`, which is used to `extend()` a `NotificationCompat.Builder`.

Finally, the resulting `Notification` is raised using a `NotificationManagerCompat` instance.

The Receiver

Our `VoiceReceiver`, registered in the manifest, is set up to respond to the voice action:

```
package com.commonsware.android.wearvoice;

import android.content.BroadcastReceiver;
import android.content.Context;
import android.content.Intent;
```

```
import android.os.Bundle;
import android.support.v4.app.RemoteInput;
import android.util.Log;
import android.widget.TextView;

public class VoiceReceiver extends BroadcastReceiver {
  static final String EXTRA_SPEECH="speech";

  @Override
  public void onReceive(Context ctxt, Intent i) {
    Bundle input=RemoteInput.getResultsFromIntent(i);

    if (input!=null) {
      CharSequence speech=input.getCharSequence(EXTRA_SPEECH);

      if (speech!=null) {
        Log.d(getClass().getSimpleName(), speech.toString());
      }
      else {
        Log.e(getClass().getSimpleName(), "No voice response speech");
      }
    }
    else {
      Log.e(getClass().getSimpleName(), "No voice response Bundle");
    }
  }
}
```

(from Notifications/VoiceInput/app/src/main/java/com/commonsware/android/wearvoice/VoiceReceiver.java)

It uses `RemoteInput.getResultsFromIntent(i)` to pick out the response we got from the user for this action. There are three major possibilities:

1. We did not get any response (should not happen)
2. We got a response, but for whatever reason, the decoded `Bundle` is missing our `VoiceReceiver.EXTRA_SPEECH` key (also should not happen)
3. The `CharSequence` from the `VoiceReceiver.EXTRA_SPEECH` key in the decoded `Bundle` is the user's response, whether from speech recognition or from choosing one of our canned responses

In this case, we just log the message to Logcat, but in principle you could do whatever you wanted. Just bear in mind that your UI may not be in the foreground, and that the device screen may be off entirely. It is also possible that your process will have been terminated between the time you raised the `Notification` and the user got around to responding to it from the Wear device. Hence, you should be

making few assumptions about the environment at the point when you get the voice response.

The Results

The Wear device starts off with a typical action:

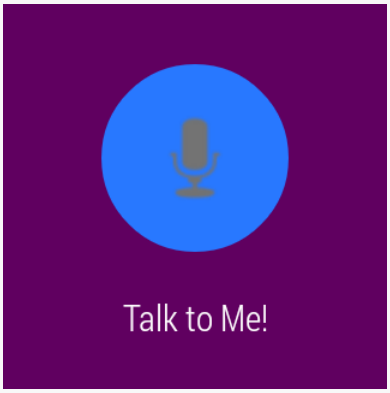

Figure 411: VoiceInput Demo, on a Samsung Galaxy Wear, Showing Voice Action

Tapping it brings up a voice input screen, where the user can dictate some text:

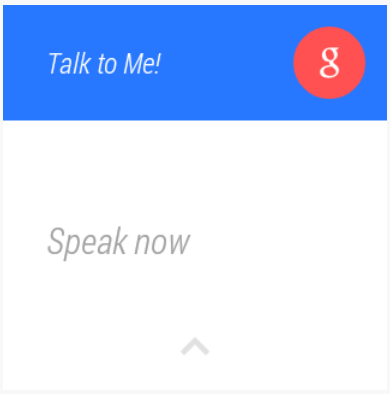

Figure 412: WearActions Demo, on a Samsung Galaxy Wear, Showing Voice Input

If the user delays too long without saying anything recognizable, or if the user swipes up the screen, they are taken to our list of canned responses:

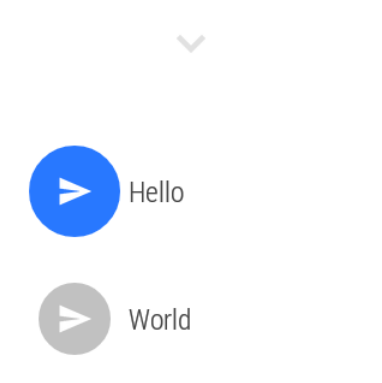

Figure 413: WearActions Demo, on a Samsung Galaxy Wear, Showing Canned Responses

If the user instead does dictate some text, initially they are shown just the interpreted text:

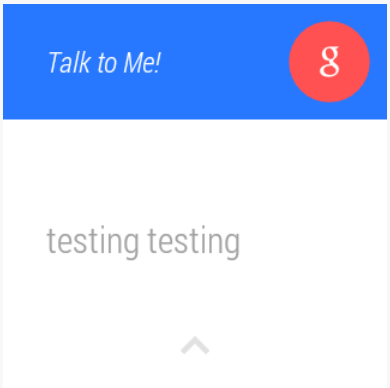

Figure 414: WearActions Demo, on a Samsung Galaxy Wear, Showing Voice Input Results

Then a cancel button with a progress indicator around the edge appears:

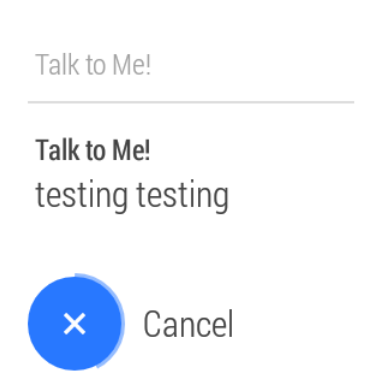

Figure 415: WearActions Demo, on a Samsung Galaxy Wear, Showing Voice Input Progress

If the user taps the cancel button before the progress indicator elapses, they are prompted to confirm or reject the input:

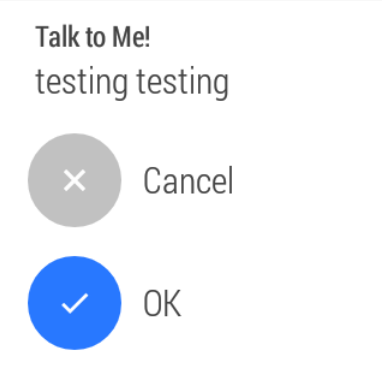

Figure 416: WearActions Demo, on a Samsung Galaxy Wear, Showing Voice Input Confirmation

Remote Input, On-Device

As is noted above, Android Wear uses `RemoteInput` to get input from the user. However, historically, that capability was limited to notifications appearing on Wear.

Starting with Android 7.0, `RemoteInput` is also available for standard device notifications. Rather than using voice input, you get a small `EditText` into which the user can type something and submit it. You get what the user typed in, and can use that as needed.

The Notifications/RemoteInput sample project is a near-clone of the Notifications/VoiceInput sample project profiled in the advanced Notifications chapter. Instead of putting the RemoteInput in an action on the WearExtender, it puts the RemoteInput on the main Notification itself:

```
package com.commonsware.android.remoteinput;

import android.app.Activity;
import android.app.NotificationChannel;
import android.app.NotificationManager;
import android.app.PendingIntent;
import android.content.Intent;
import android.os.Build;
import android.os.Bundle;
import android.support.v4.app.NotificationCompat;
import android.support.v4.app.NotificationManagerCompat;
import android.support.v4.app.RemoteInput;

public class MainActivity extends Activity {
  static final String CHANNEL_WHATEVER="channel_whatever";

  @Override
  public void onCreate(Bundle savedInstanceState) {
    super.onCreate(savedInstanceState);

    NotificationManager mgr=
      (NotificationManager)getSystemService(NOTIFICATION_SERVICE);

    if (Build.VERSION.SDK_INT>=Build.VERSION_CODES.O &&
      mgr.getNotificationChannel(CHANNEL_WHATEVER)==null) {
      mgr.createNotificationChannel(new NotificationChannel(CHANNEL_WHATEVER,
        "Whatever", NotificationManager.IMPORTANCE_DEFAULT));
    }

    Intent i=new Intent(this, RemoteInputReceiver.class);
    PendingIntent pi=
        PendingIntent.getBroadcast(this, 0, i,
          PendingIntent.FLAG_UPDATE_CURRENT);

    RemoteInput remoteInput=
        new RemoteInput.Builder(RemoteInputReceiver.EXTRA_INPUT)
          .setLabel(getString(R.string.talk))
          .build();

    NotificationCompat.Action remoteAction=
        new NotificationCompat.Action.Builder(
              android.R.drawable.ic_btn_speak_now,
```

```
              getString(R.string.talk),
              pi).addRemoteInput(remoteInput).build();

    NotificationCompat.Builder builder=
      RemoteInputReceiver.buildNotificationBase(this)
        .addAction(remoteAction);

    NotificationManagerCompat
      .from(this)
      .notify(RemoteInputReceiver.NOTIFY_ID, builder.build());

    finish();
  }
}
```

(from Notifications/RemoteInput/app/src/main/java/com/commonsware/android/remoteinput/MainActivity.java)

The activity, when launched, will raise the `Notification` with a "Talk to Me" action:

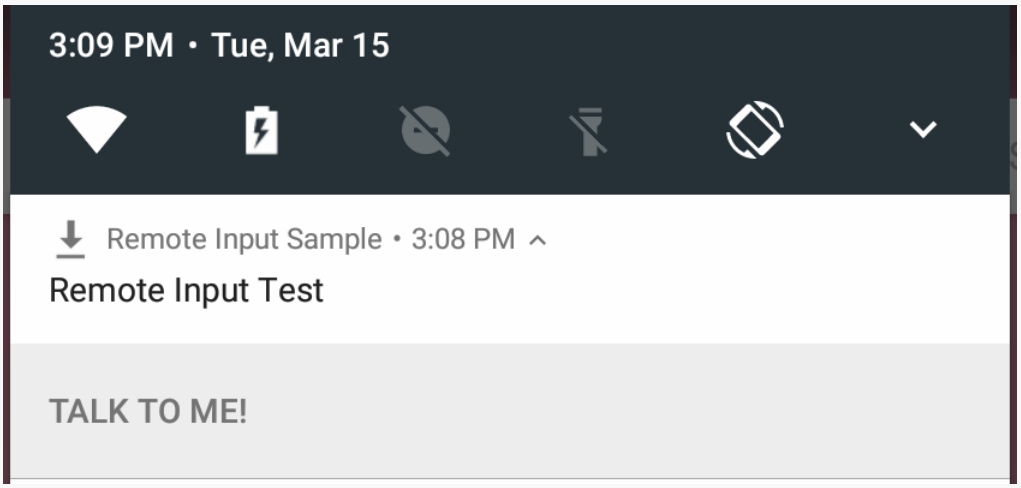

Figure 417: Notification with Action

Tapping on the action converts it into an `EditText`, with your action prompt as the hint, plus an arrow-shaped "send" button:

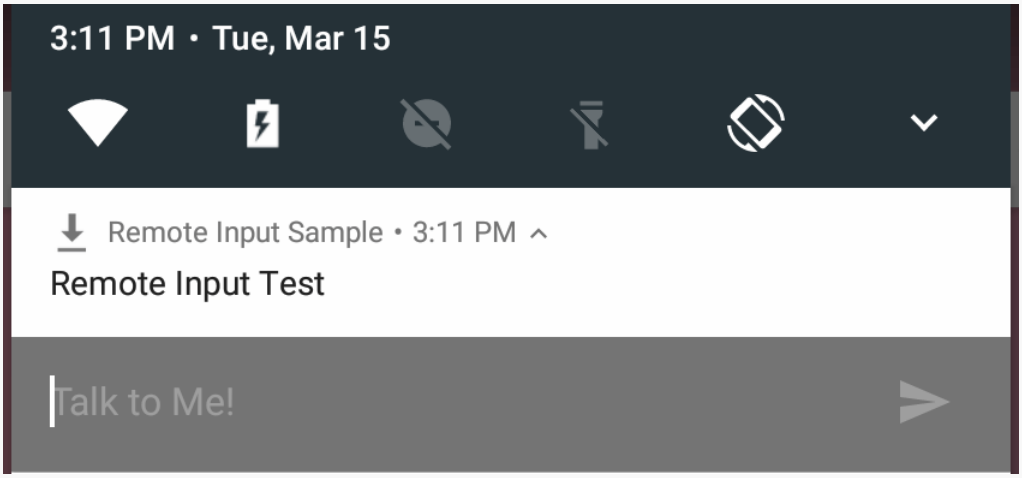

Figure 418: Notification with Remote Input

Typing something in and tapping that button converts the button into a progress spinner:

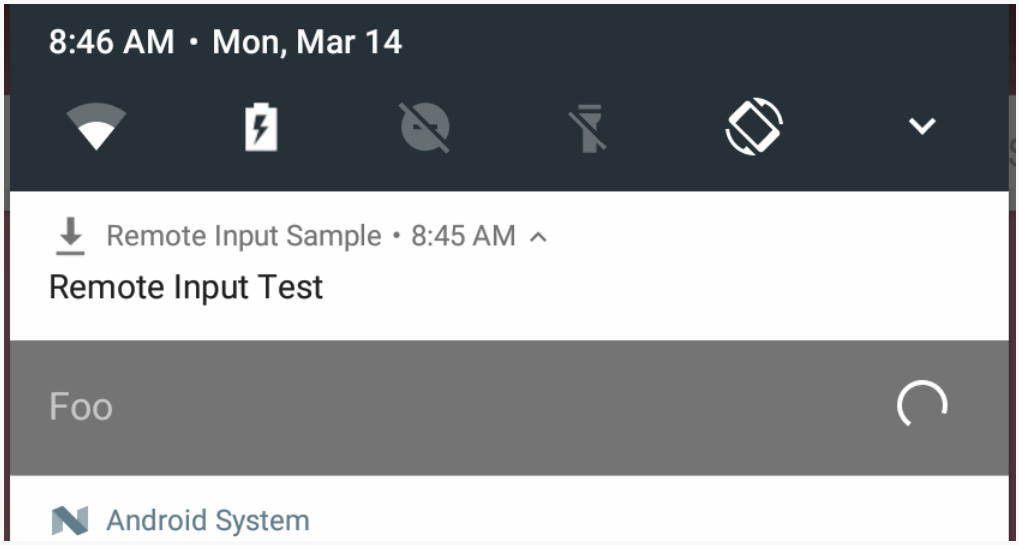

Figure 419: Notification with Remote Input and Progress Spinner

Also, the `PendingIntent` that you associated with the action is invoked. In this case, that triggers a broadcast to `RemoteInputReceiver`:

```
package com.commonsware.android.remoteinput;

import android.content.BroadcastReceiver;
import android.content.Context;
```

```
import android.content.Intent;
import android.os.Bundle;
import android.support.v4.app.NotificationCompat;
import android.support.v4.app.NotificationManagerCompat;
import android.support.v4.app.RemoteInput;
import android.util.Log;

public class RemoteInputReceiver extends BroadcastReceiver {
  static final int NOTIFY_ID=1337;
  static final String EXTRA_INPUT="input";

  static NotificationCompat.Builder buildNotificationBase(Context ctxt) {
    NotificationCompat.Builder builder=
      new NotificationCompat.Builder(ctxt, MainActivity.CHANNEL_WHATEVER)
        .setSmallIcon(
          android.R.drawable.stat_sys_download_done)
        .setContentTitle(ctxt.getString(R.string.title));

    return(builder);
  }

  @Override
  public void onReceive(Context ctxt, Intent i) {
    Bundle input=RemoteInput.getResultsFromIntent(i);

    if (input!=null) {
      CharSequence speech=input.getCharSequence(EXTRA_INPUT);

      if (speech!=null) {
        Log.d(getClass().getSimpleName(), speech.toString());
      }
      else {
        Log.e(getClass().getSimpleName(), "No voice response speech");
      }
    }
    else {
      Log.e(getClass().getSimpleName(), "No voice response Bundle");
    }

    NotificationCompat.Builder builder=
      buildNotificationBase(ctxt);

    NotificationManagerCompat
      .from(ctxt)
      .notify(RemoteInputReceiver.NOTIFY_ID, builder.build());
  }
}
```

(from Notifications/RemoteInput/app/src/main/java/com/commonsware/android/remoteinput/RemoteInputReceiver.java)

Here, we get what the user typed in via our designated extra (`EXTRA_INPUT`, as requested via the `RemoteInput.Builder`), which we can use as we see fit, such as logging it to Logcat.

However, we *also* have to update or cancel the `Notification`. Otherwise, that progress spinner will spin indefinitely. If the `Notification` still has value to the user after the `RemoteInput`, just update it, with or without another `RemoteInput` (depending on whether one would now be needed). You might also show the user's input in the updated `Notification`. Or, if the `Notification` is no longer needed, just `cancel()` it. In this case, we raise a fresh `Notification` for this ID, just without the `RemoteInput` that the activity added.

Note that `setChoices()` on `RemoteInput` is ignored for regular device notifications. You can use this for Wear notifications to give the user a list of strings to choose from, as an alternative to voice recognition.

You can call `setRemoteInputHistory()` on your `Builder` as well. This takes a `CharSequence` array, though many developers will elect to use a simple `String` array. This represents the inputs supplied by the user and accepted by your app, in reverse chronological order (first element in the array is the most recent input). Some of this history may be added automatically to the `Notification` when you raise the updated `Notification` containing this input history.

Notification Groups

Another concept introduced with Wear in mind was the notification group. With this, you create a summary `Notification`, along with detail `Notifications` for individual events. The quintessential example is an email app, with a summary `Notification` indicating the unread message count, and with detail `Notifications` for individual messages.

The idea for Wear was to allow the user to individually respond to the detail `Notifications` without having to pull out the associated phone or tablet. That phone or tablet would show the summary `Notification`, since the user could just tap on it and bring up the activity to see the detail.

For some reason, Google back-pedaled on that last part, as with Android 7.0, phones and tablets will also show the summary-and-detail `Notification` hierarchy.

The `Notifications/Stacked` sample project, presented in the chapter on advanced `Notifications`, demonstrates this without any modifications. Initially, the user just sees the summary:

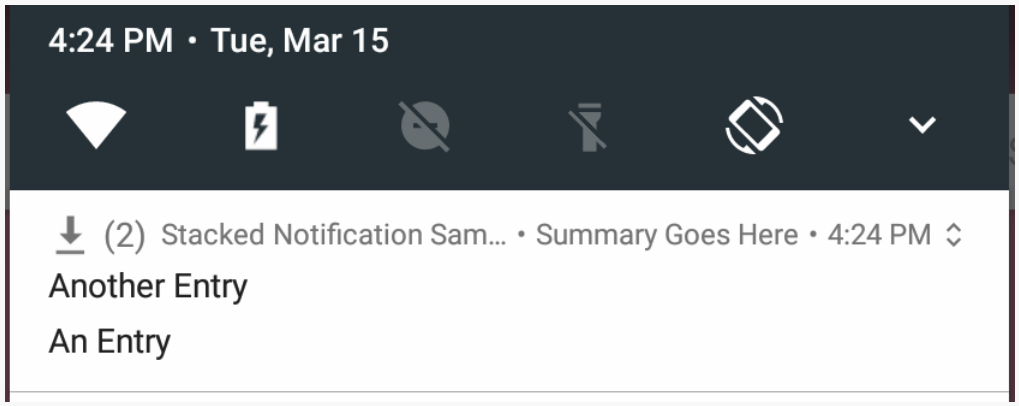

Figure 420: Stacked Notification, Showing Summary

A two-finger swipe gesture will expose the full hierarchy:

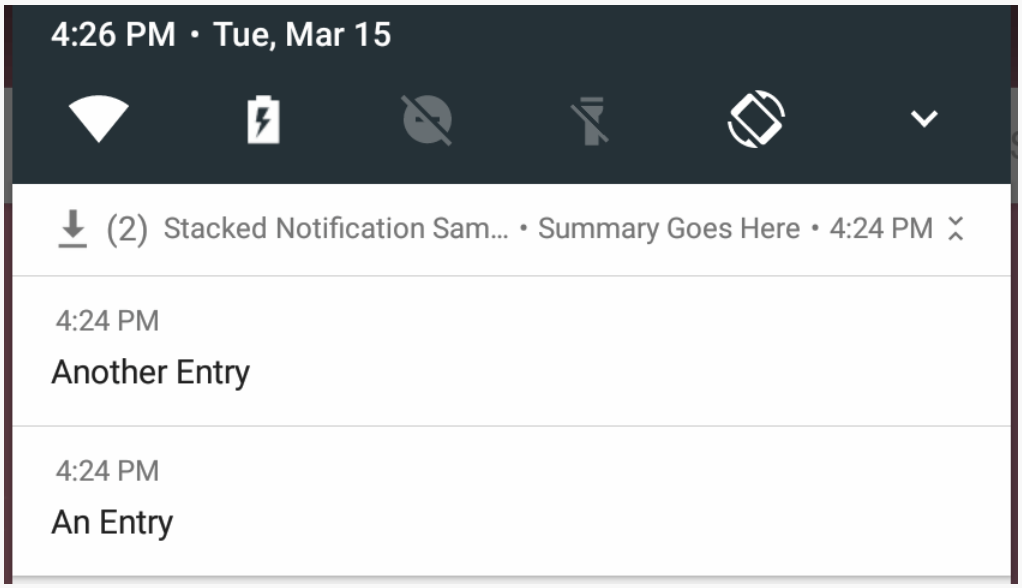

Figure 421: Stacked Notification, Showing Hierarchy

Lockscreen Notifications

Historically, notification icons would be visible on the user's lockscreen, but that was it. This would give the user an indication of what apps need attention, but no additional context.

Android 5.0 added notifications to the lockscreen, to help provide that missing context. Now users can have more details about the notifications, to determine whether it is necessary to unlock the device right now to deal with them.

Also note that on Android 7.0+, `RemoteInput` works on the lockscreen. You can see this in action with the sample app — just leave the `Notification` up, then lock the device. When you power on the screen again, you will get the lockscreen, and the `Notification` tile will appear. It will not visibly show any sign of remote input, but if you swipe down on the `Notification`, the remote input field will appear, and you can type in a message.

However, this also raises privacy concerns, as now notification text can be seen by anyone with access to the phone. As such, Android 5.0 introduced the concept of *visibility* to notifications, so developers can help control what is shown on the lockscreen versus what is shown only past the lockscreen.

However, these visibility options are only useful if:

- The device has a pattern, PIN, or password set, so it is not merely some swipe-to-unlock approach
- The user has indicated that the system should "hide sensitive notification content", either when they set up the pattern/PIN/password:

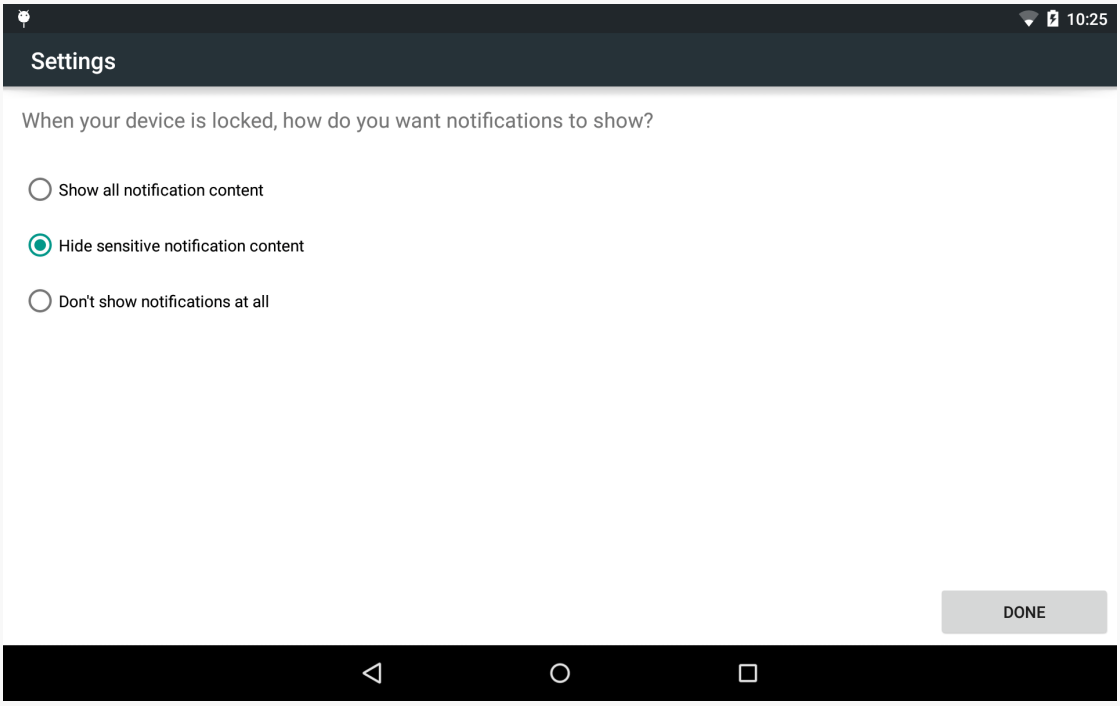

Figure 422: Choosing Notification Control, When Securing the Lockscreen

or in the “Sound & notification” portion of the Settings app:

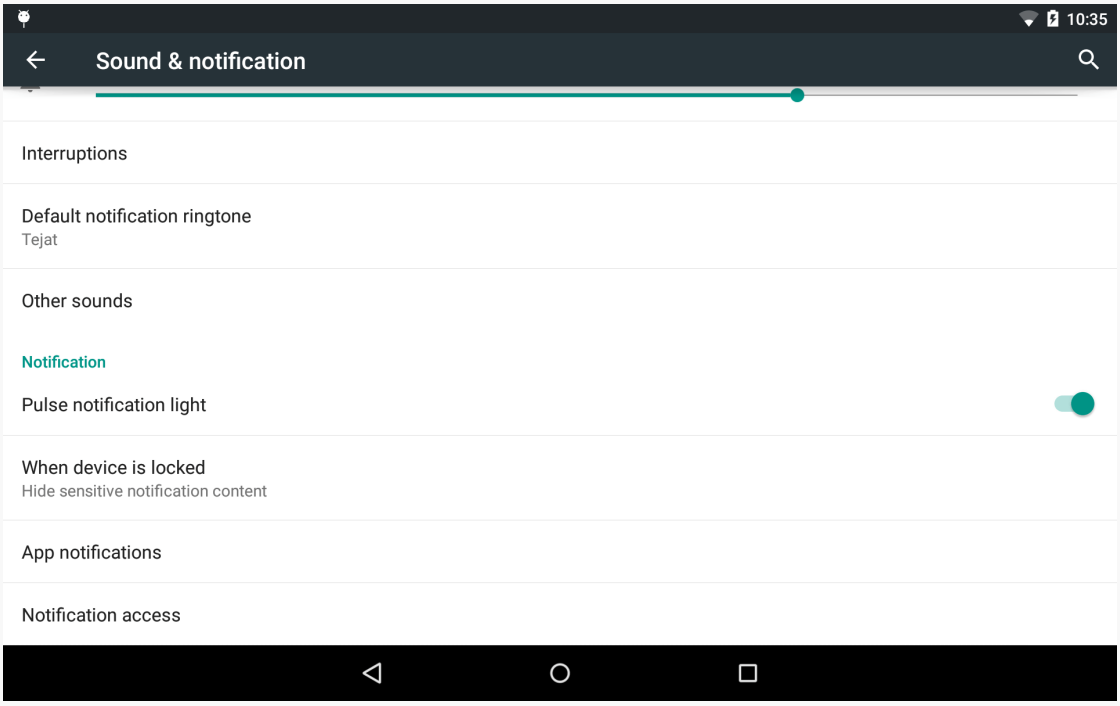

Figure 423: "Sound & notification" Settings

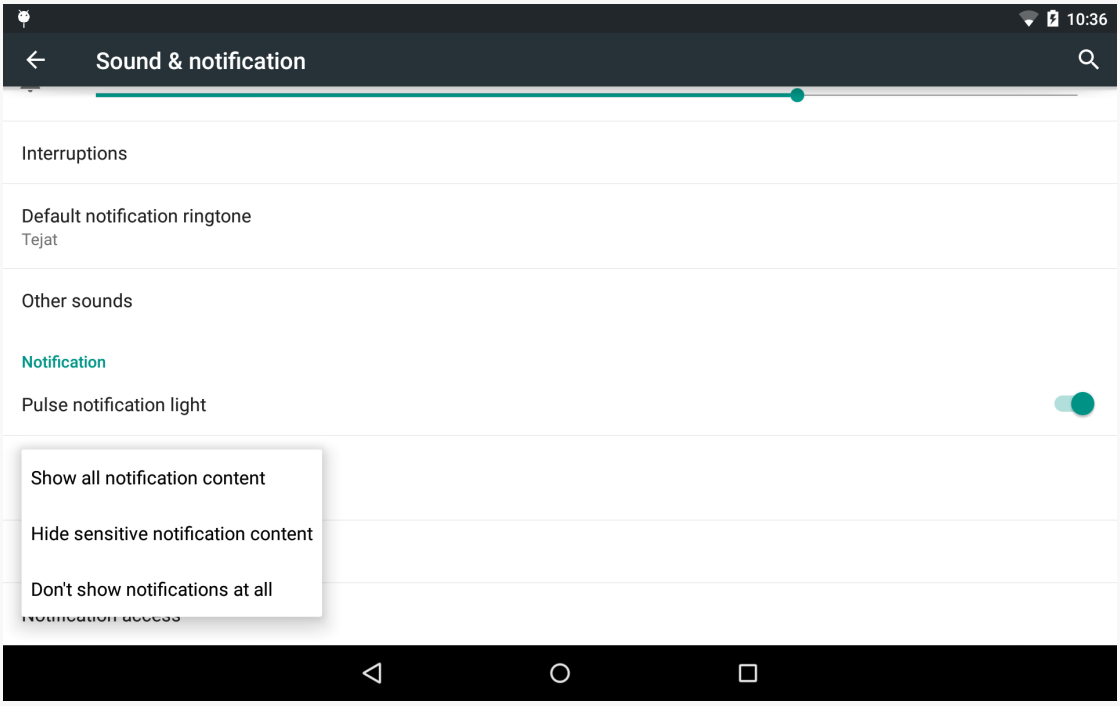

Figure 424: Notification Control Options in "Sound & notification" in Settings

Given that the user has enabled "hide sensitive notification content" mode, you as a developer can choose a visibility to apply to your notifications. There are three such visibility options — private, public, and secret — covered in the following sections.

Private Notifications

The default behavior is a "private" `Notification`. Basic information appears on the lockscreen, but not the whole `Notification`. However, you as a developer can also provide a *separate* `Notification` that *will* be shown on the lockscreen, so you can choose what information appears publicly and what information does not.

The sample app for this section has a "public" edition of the `Notification` that shows up on the lockscreen:

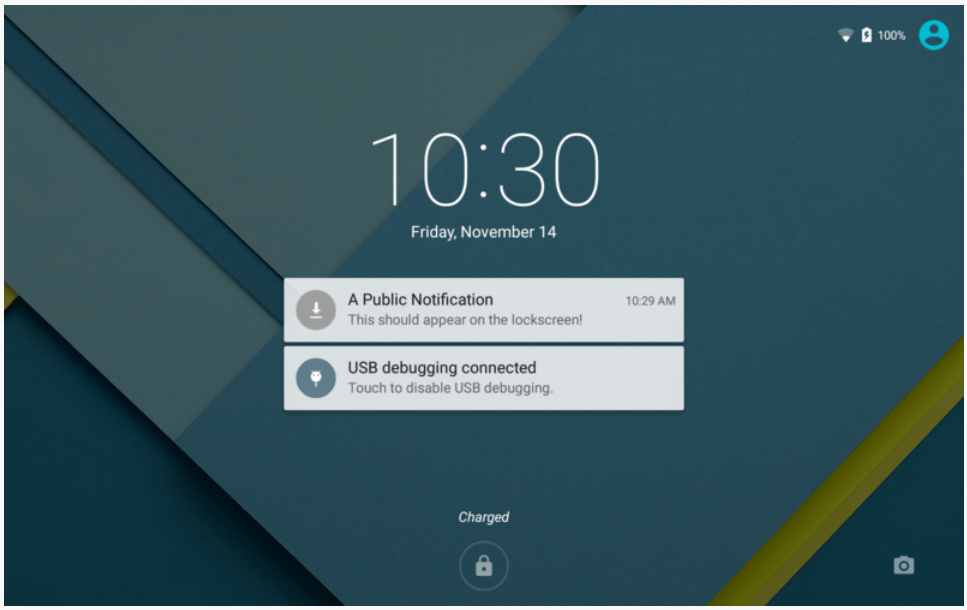

Figure 425: Public Edition of Private Lockscreen Notification, on a Nexus 7

Public Notifications

Instead of creating a separate `Notification` for public visibility on the lockscreen, you could flag your main `Notification` as having public visibility. This is suitable for notifications where there is little to no privacy implications for having the information appear on the lockscreen.

Secret Notifications

A `Notification` with visibility set to "secret" will not show up on the lockscreen at all. The ringtone, etc. will occur, as requested (and based on device settings, like it being muted), but otherwise there is no visible indication on the lockscreen that your `Notification` exists. Only when the user gets past the lockscreen will your `Notification` appear, in the status bar.

A Visibility Sample

The `Notifications/Lollipop` sample project demonstrates the use of these visibility values. It also demonstrates heads-up notifications, covered later in this chapter.

The user interface consists of a `Spinner` of possible `Notification` variants, a `SeekBar` to allow the user to specify a delay period in seconds before showing the `Notification`, and a `Button` to trigger showing the `Notification`:

```
<?xml version="1.0" encoding="utf-8"?>

<TableLayout
    xmlns:android="http://schemas.android.com/apk/res/android"
    android:layout_width="match_parent"
    android:layout_height="match_parent"
    android:padding="8dp"
    android:stretchColumns="1">

    <TableRow>
        <TextView
            android:text="@string/type_label"/>

        <Spinner
            android:id="@+id/type"/>
    </TableRow>

    <TableRow>
        <TextView
            android:text="@string/delay_label"/>

        <SeekBar
            android:id="@+id/delay"
            android:progress="5"
            android:max="30"/>
    </TableRow>

    <Button
```

```
        android:text="@string/notify_button"
        android:id="@+id/download"
        android:onClick="notifyMe"/>
</TableLayout>
```

(from Notifications/Lollipop/app/src/main/res/layout/main.xml)

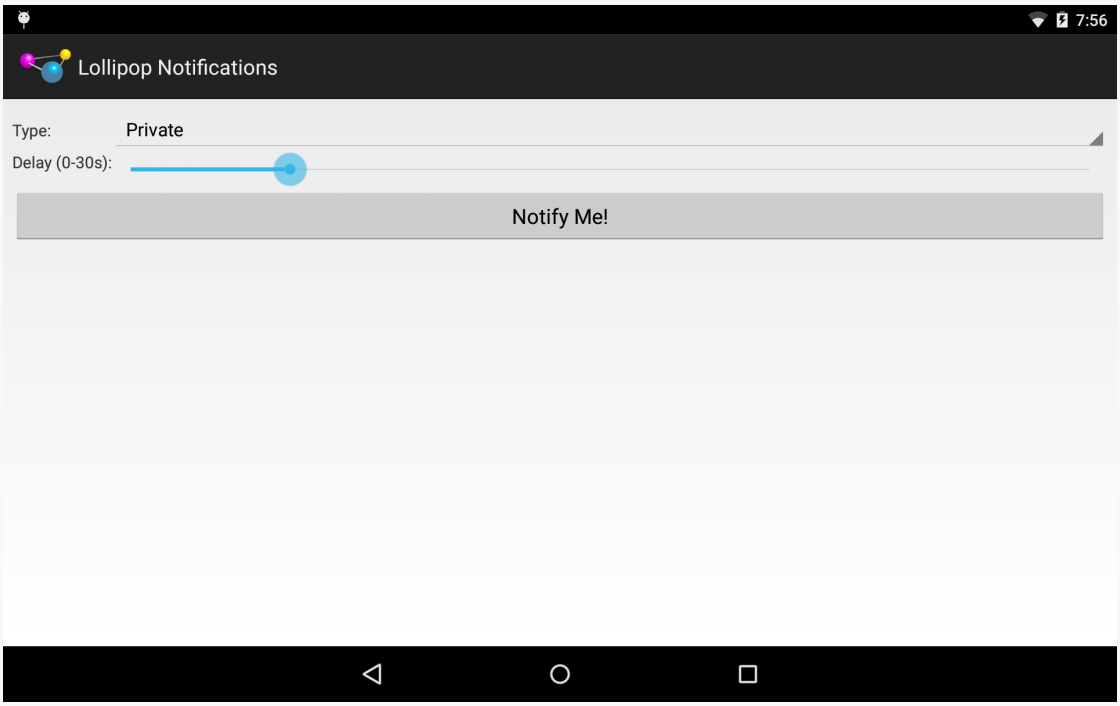

Figure 426: Lollipop Notifications Demo, on a Nexus 7

The `onCreate()` method of our launcher activity (`MainActivity`) initializes the UI:

```
package com.commonsware.android.lollipopnotify;

import android.app.Activity;
import android.app.AlarmManager;
import android.app.PendingIntent;
import android.content.Intent;
import android.os.Bundle;
import android.os.SystemClock;
import android.view.View;
import android.widget.ArrayAdapter;
import android.widget.SeekBar;
import android.widget.Spinner;

public class MainActivity extends Activity {
  private Spinner type=null;
  private SeekBar delay=null;

  @Override
```

```
  public void onCreate(Bundle savedInstanceState) {
    super.onCreate(savedInstanceState);
    setContentView(R.layout.main);

    type=(Spinner)findViewById(R.id.type);

    ArrayAdapter<String> types=
        new ArrayAdapter<String>(this,
            android.R.layout.simple_spinner_item,
            getResources().getStringArray(R.array.types));

    types.setDropDownViewResource(android.R.layout.simple_spinner_dropdown_item);
    type.setAdapter(types);

    delay=(SeekBar)findViewById(R.id.delay);
  }

  public void notifyMe(View v) {
    Intent i=new Intent(this, AlarmReceiver.class)
        .putExtra(AlarmReceiver.EXTRA_TYPE, type.getSelectedItemPosition());
    PendingIntent pi=PendingIntent.getBroadcast(this, 0, i,
                                            PendingIntent.FLAG_UPDATE_CURRENT);
    AlarmManager mgr=(AlarmManager)getSystemService(ALARM_SERVICE);

    mgr.set(AlarmManager.ELAPSED_REALTIME_WAKEUP,
        SystemClock.elapsedRealtime()+(1000*delay.getProgress()),
        pi);
  }
}
```

(from Notifications/Lollipop/app/src/main/java/com/commonsware/android/lollipopnotify/MainActivity.java)

In particular, `onCreate()` populates the `Spinner` based on a `<string-array>` resource:

```
<?xml version="1.0" encoding="utf-8"?>
<resources>
    <string-array name="types">
        <item>Private</item>
        <item>Public</item>
        <item>Secret</item>
        <item>Heads-Up</item>
    </string-array>
</resources>
```

(from Notifications/Lollipop/app/src/main/res/values/arrays.xml)

When the button is clicked, the `notifyMe()` method on `MainActivity` is called. Here, we:

- Create an `Intent` pointing at an `AlarmReceiver`
- Package an extra on the `Intent` that contains the selected position of the `Spinner`

- Wrap the `Intent` in a `getBroadcast()` `PendingIntent`
- Use `set()` on `AlarmManager` to invoke the `PendingIntent` after the delay period specified via the `SeekBar`

Since the `targetSdkVersion` of this project is below 19, the `set()` method will behave in an exact fashion, triggering our `AlarmReceiver` at the designated time.

`AlarmReceiver`, in turn, uses a `switch` statement to call out to different private methods based upon which `Spinner` item was selected:

```
package com.commonsware.android.lollipopnotify;

import android.app.Notification;
import android.app.NotificationChannel;
import android.app.NotificationManager;
import android.app.PendingIntent;
import android.content.BroadcastReceiver;
import android.content.Context;
import android.content.Intent;
import android.os.Build;
import android.provider.Settings;
import android.support.v4.app.NotificationCompat;
import android.support.v4.app.NotificationManagerCompat;

public class AlarmReceiver extends BroadcastReceiver {
  private static final String CHANNEL_WHATEVER="channel_whatever";
  private static final String CHANNEL_HEADS_UP="channel_heads_up";
  private static final int NOTIFY_ID=1337;
  static final String EXTRA_TYPE="type";

  @Override
  public void onReceive(Context ctxt, Intent i) {
    NotificationManager mgr=
      (NotificationManager)ctxt.getSystemService(Context.NOTIFICATION_SERVICE);

    if (Build.VERSION.SDK_INT>=Build.VERSION_CODES.O &&
      mgr.getNotificationChannel(CHANNEL_WHATEVER)==null) {
      mgr.createNotificationChannel(new NotificationChannel(CHANNEL_WHATEVER,
        "Whatever", NotificationManager.IMPORTANCE_DEFAULT));
      mgr.createNotificationChannel(new NotificationChannel(CHANNEL_HEADS_UP,
        "Heads Up!", NotificationManager.IMPORTANCE_HIGH));
    }

    NotificationManagerCompat mgrCompat=NotificationManagerCompat.from(ctxt);

    switch (i.getIntExtra(EXTRA_TYPE, -1)) {
      case 0:
        notifyPrivate(ctxt, mgrCompat);
        break;

      case 1:
        notifyPublic(ctxt, mgrCompat);
        break;

      case 2:
```

```
      notifySecret(ctxt, mgrCompat);
      break;

    case 3:
      notifyHeadsUp(ctxt, mgrCompat);
      break;
  }
}

private void notifyPrivate(Context ctxt, NotificationManagerCompat mgr) {
  Notification pub=
    buildBase(ctxt, CHANNEL_WHATEVER, R.string.public_title).build();

  mgr.notify(NOTIFY_ID,
    buildBase(ctxt, CHANNEL_WHATEVER, R.string.private_title).setPublicVersion(pub).build());
}

private void notifyPublic(Context ctxt, NotificationManagerCompat mgr) {
  mgr.notify(NOTIFY_ID,
      buildBase(ctxt, CHANNEL_WHATEVER, R.string.public_title)
          .setVisibility(NotificationCompat.VISIBILITY_PUBLIC)
          .build());
}

private void notifySecret(Context ctxt, NotificationManagerCompat mgr) {

      buildBase(ctxt, CHANNEL_WHATEVER, R.string.secret_title)
          .setVisibility(NotificationCompat.VISIBILITY_SECRET)
          .build());
}

private void notifyHeadsUp(Context ctxt, NotificationManagerCompat mgr) {
  mgr.notify(NOTIFY_ID,
      buildBase(ctxt, CHANNEL_HEADS_UP, R.string.headsup_title)
          .setPriority(NotificationCompat.PRIORITY_HIGH)
          .build());
}

private NotificationCompat.Builder buildBase(Context ctxt, String channel,
                                             int titleId) {
  NotificationCompat.Builder b=
    new NotificationCompat.Builder(ctxt, channel);

  b.setAutoCancel(true)
      .setDefaults(Notification.DEFAULT_ALL)
      .setContentTitle(ctxt.getString(titleId))
      .setContentIntent(buildPendingIntent(ctxt, Settings.ACTION_SECURITY_SETTINGS))
      .setSmallIcon(android.R.drawable.stat_sys_download_done)
      .addAction(android.R.drawable.ic_media_play,
          ctxt.getString(R.string.play),
          buildPendingIntent(ctxt, Settings.ACTION_SETTINGS));

  return(b);
}

private PendingIntent buildPendingIntent(Context ctxt, String action) {
  Intent i=new Intent(action);

  return(PendingIntent.getActivity(ctxt, 0, i, 0));
```

```
  }
}
```

(from Notifications/Lollipop/app/src/main/java/com/commonsware/android/lollipopnotify/AlarmReceiver.java)

If the user chooses the "Private" option in the `Spinner`, we call `notifyPrivate()`. That method builds two `Notification` objects: the regular one and a separate public edition. We attach the public edition to the regular `Notification` via a call to `setPublicVersion()` on the `NotificationCompat.Builder`. Then, we raise the regular `Notification`. This will show the public edition if the lockscreen is locked; otherwise, it will show the regular edition.

If the user chooses the "Public" option, we call `notifyPublic()`. That, in turn, calls `setVisibility(NotificationCompat.VISIBILITY_PUBLIC)` on the `NotificationCompat.Builder`, causing our `Notification` to appear normally both on the lockscreen and past the lockscreen.

If the user chooses the "Secret" option, we call `notifySecret()`. That uses `setVisibility(NotificationCompat.VISIBILITY_SECRET)` to configure the `Notification` to only appear once the user has gotten past the lockscreen.

The "Heads-Up" option — fourth in the `Spinner` — is covered in the next section.

Priority, Importance, and Heads-Up Notifications

Notifications can have a priority associated with them. Normally, notifications with higher priority will appear higher in the list of notifications in the notification tray than will notifications with lower priority.

Android 5.0 took this a step further, showing high-priority notifications in a "heads-up" style, popping up a small dialog-like window over the main screen, with the same basic content as would appear for the `Notification` in its tile in the notification tray:

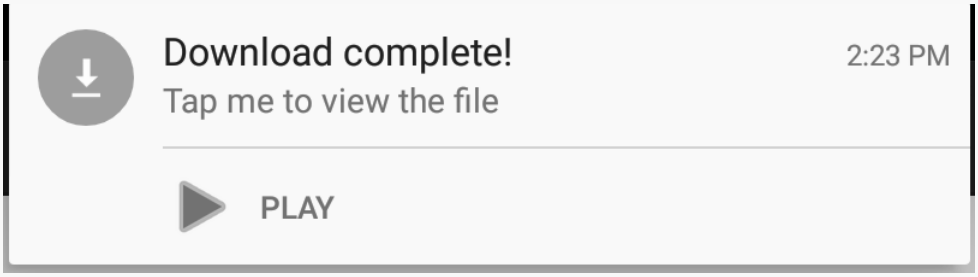

Figure 427: Lollipop Demo, on a Nexus 7, Showing Heads-Up Notification

Users can interact with the heads-up `Notification` or ignore it; in the latter case, the `Notification` will move into the status bar and the "heads-up" display will disappear from the screen.

Note that the "priority" concept being described here seems to be independent of the notion of "priority notifications" in the user's interruption configuration in Settings. There, "priority notifications" is tied to the app, not tied to any sort of configuration of the `Notification` itself.

Android 8.0's notification channels introduced a separate concept, called importance, set on the channel. Roughly speaking, importance on a channel is the same as priority on a notification. Priorities are marked as deprecated on API Level 26+, though they still work.

Specifying the Priority

`NotificationCompat.Builder` has a `setPriority()` method that allows you to specify your requested priority. There are five priority values accepted as a parameter, all defined as constants out on the `NotificationCompat` class:

- `PRIORITY_MAX`
- `PRIORITY_HIGH`
- `PRIORITY_DEFAULT`
- `PRIORITY_LOW`
- `PRIORITY_MIN`

The actual priority applied to the `Notification` will depend upon other factors, and so you should not assume that your requested value will be accepted and applied as-is.

Results on Android 5.x Devices

The heads-up `Notification` appears as shown in the above screenshot. The pop-up itself is centered across the top of the screen, as shown below:

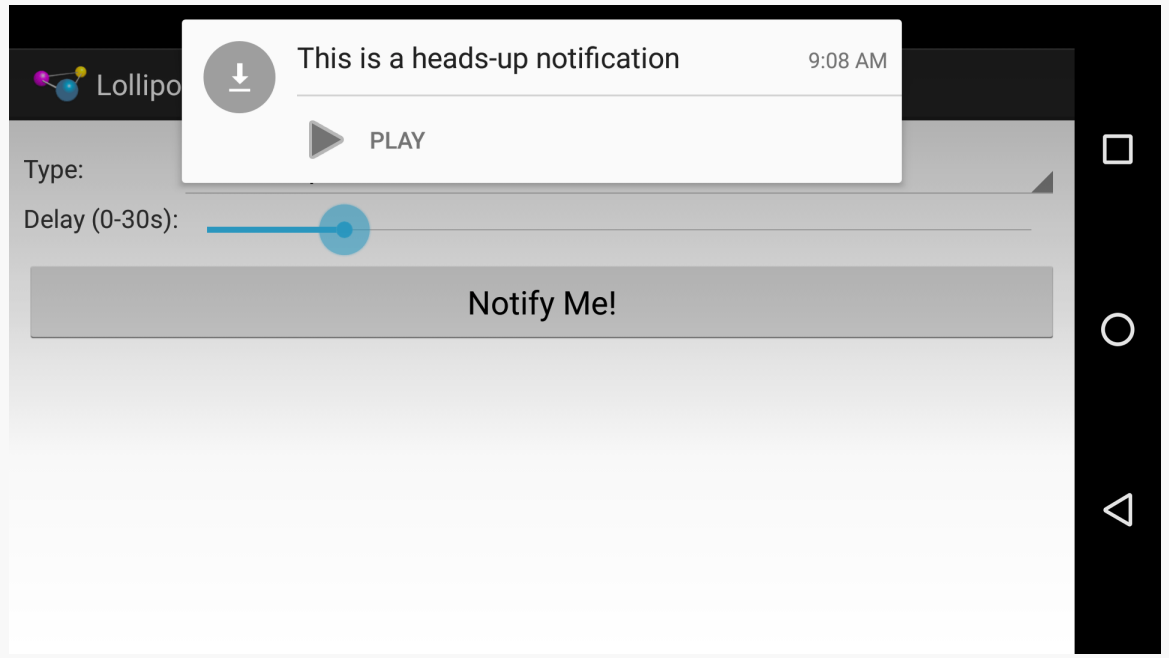

Figure 428: Lollipop Demo, Showing Heads-Up Notification

After a few seconds of inactivity, the pop-up vanishes, and the `Notification` goes into the status bar.

Results on Older Devices

The concept of priority was introduced in API Level 16 (Android 4.1). On Android 4.1 through 4.4, the only effect of priority was to help influence the sort order of notifications in the notification tray, with higher-priority items drifting towards the top.

While `NotificationCompat.Builder` will allow you to specify a priority even on devices running older versions of Android than 4.1, the requested priority will be ignored, simply because priority did not exist back then. Hence, while your code will still work, it will have no effect on such old devices.

Full-Screen Notifications

Before Android 5.0 added heads-up notifications, while priority would influence things like sort order, it would have no real impact on how the user would be informed about whatever event triggered the `Notification`. The user would still just get an icon in the status bar, and perhaps a ringtone and other hardware output.

However, sometimes we need to be somewhat more "in the user's face", such as for a calendar event reminder, or for an incoming phone call from our VOIP app.

It is tempting to launch an activity in these cases. In fact, that is what the user tends to perceive as happening, on Android 4.4 and older devices. And some apps no doubt actually do launch an activity.

A "middle ground" between showing a `Notification` and launching an activity is to use a full-screen `Notification`. Here, we provide a `PendingIntent` that should be invoked if the user is actively using the device at the time of the `Notification`. Typically, that `PendingIntent` will display an activity. However, on Android 5.0+, the behavior has changed, where a full-screen `Notification` actually just triggers a heads-up notification, as would a high-priority `Notification`.

Requesting Full-Screen Output

Prior to Android 8.0, all that you need to do to set up a `Notification` to be full-screen is to call `setFullScreenIntent()` on your `NotificationCompat.Builder`, supplying two values:

1. A `PendingIntent` to be invoked when the notification is added to the screen
2. A `boolean`, where `true` indicates that even if the user has blocked notifications, you want this one to appear

For example, in the [Notifications/FullScreen]() sample project, `MainActivity` shows a `Notification` constructed via the `buildNormal()` method:

```
private NotificationCompat.Builder buildNormal() {
  NotificationCompat.Builder b=
    new NotificationCompat.Builder(this, CHANNEL_WHATEVER);

  b.setAutoCancel(true)
   .setDefaults(Notification.DEFAULT_ALL)
   .setContentTitle(getString(R.string.download_complete))
   .setContentText(getString(R.string.fun))
   .setContentIntent(buildPendingIntent(Settings.ACTION_SECURITY_SETTINGS))
```

```
    .setSmallIcon(android.R.drawable.stat_sys_download_done)
     .setNumber(5)
    .setFullScreenIntent(buildPendingIntent(Settings.ACTION_DATE_SETTINGS), true)
    .addAction(android.R.drawable.ic_media_play,
        getString(R.string.play),
        buildPendingIntent(Settings.ACTION_SETTINGS));

  return(b);
```

(from Notifications/FullScreen/app/src/main/java/com/commonsware/android/fullscreen/MainActivity.java)

Here, the `PendingIntent` is created using the same `buildPendingIntent()` method as before, this time opening up a distinct screen from the Settings app.

Results on Android 5.0-7.1 Devices

On Android 5.0 through 7.1, the "full screen" `Notification` appears as a heads-up `Notification`:

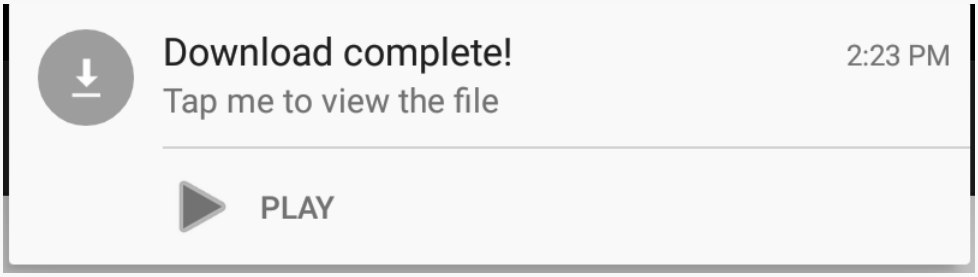

Figure 429: FullScreen Demo, on a Nexus 7, Showing "Full Screen" Notification

Note that there is no obvious way to actually invoke the `PendingIntent` associated with the `setFullScreenIntent()` method. Hence, you need to make sure that the `Notification` has some other means of getting the user to the right place in your UI, such as via `setContentIntent()` or an action.

Results on Android 3.0-4.4 Devices

On API Levels 11 through 19 (Android 3.0 through 4.4), the effect of a full-screen `PendingIntent` is to invoke the `PendingIntent` when the `Notification` is added to the screen. This will happen regardless of whether the user is using the device or not, though if the device is asleep, the activity triggered by the `PendingIntent` will only be visible once the user gets past their lockscreen.

Note that the `Notification` is *also* shown, along with whatever the `PendingIntent` does. That `Notification` is not automatically cleared when the user exits out of that

activity via BACK, HOME, etc. Hence, it is up to you to clear that `Notification` if and when it is no longer relevant. The primary value of the `Notification` is to have the icon appear in the status bar on the lockscreen — even though the user cannot interact with your `Notification` then, the user may recognize your icon and therefore elect to unlock their device to see what all the fuss is about.

Results on Older Devices

Full-screen notifications were not supported prior to Android 3.0. While `NotificationCompat.Builder` will allow you to call `setFullScreenIntent()`, the value will be ignored prior to API Level 11.

In theory, there is nothing stopping `NotificationCompat` from launching an activity itself, in addition to displaying the `Notification`. However, at least at this time, it is not doing so, and it is fairly likely that Google will not add this in at this point.

Hence, the only way to do a "full-screen notification" is for your app to launch the desired activity, in addition to (or instead of) showing the `Notification`.

Hey, What About Android 8.0+?

On these devices, `setFullScreenIntent()` has no effect.

Progress Notifications

Often, you will see a `Notification` with a `ProgressBar` in it, showing progress of some long-running background work, such as a large download. There are two approaches towards building this sort of thing:

1. Create a custom `Notification`, as we will cover later in this chapter
2. Use `setProgress()` on the `NotificationCompat.Builder`, periodically updating the `Notification` to reflect the now-current amount of progress

Needless to say, the second option is simpler.

The `HTTP/OkHttpProgress` sample project demonstrates how this works in a fairly realistic situation: tracking progress of a long download. In this case, we will use OkHttp3, showing how you can integrate its somewhat convoluted "interceptor" API to find out about download progress, then use that information to update a `Notification`.

The UI

This sample app is a variation on other download samples shown elsewhere in the book. We have a fragment with a large "Do the Download" button. When the button is clicked, we want to start a `Downloader` service to do the actual downloading on a background thread.

The two primary differences in this fragment's `onClick()` method are:

- We are downloading a much bigger file than before — Version 1.1 of this book, from 2008. This is so we can actually see the progress move; with a short download, the download might complete before we get a chance to look at the `Notification`.
- We `finish()` the activity, to emphasize the fact that our ongoing UI is being handled by the `Notification`:

```
@Override
public void onClick(View v) {
  Intent i=new Intent(getActivity(), Downloader.class);

  i.setDataAndType(Uri.parse("http://commonsware.com/Android/Android-1_1-CC.pdf"),
                   "application/pdf");

  getActivity().startService(i);
  getActivity().finish();
}
```

(from HTTP/OkHttpProgress/app/src/main/java/com/commonsware/android/okhttp3/progress/DownloadFragment.java)

The Downloader Service

The more significant changes come in the `Downloader` service. Previous editions of this sample use `HttpURLConnection`, but here we switch to OkHttp3, which offers a cleaner way to find out our download progress. Plus, our foreground service `Notification` will employ the `ProgressBar` to show how far along we are in downloading the file.

Everything but the Icky Parts

A large chunk of our `Downloader IntentService` does the same stuff as you see in the `Notifications/Foreground` sample project.

Of particular note here, we call `startForeground()`, to elevate our process priority while the download is happening and show a `Notification` along the way:

```
    String filename=i.getData().getLastPathSegment();
    final NotificationCompat.Builder builder=
      buildForeground(filename);

    startForeground(FOREGROUND_ID, builder.build());
```

(from HTTP/OkHttpProgress/app/src/main/java/com/commonsware/android/okhttp3/progress/Downloader.java)

The `Notification` itself comes from `buildForeground()`, which takes the name of the file as a parameter and builds a `Notification` with that information:

```
private NotificationCompat.Builder buildForeground(
  String filename) {
  NotificationCompat.Builder b=new NotificationCompat.Builder(this);

  b.setContentTitle(getString(R.string.downloading))
   .setContentText(filename)
   .setSmallIcon(android.R.drawable.stat_sys_download)
   .setTicker(getString(R.string.downloading))
   .setOngoing(true);

  return(b);
}
```

(from HTTP/OkHttpProgress/app/src/main/java/com/commonsware/android/okhttp3/progress/Downloader.java)

Eventually, we start using `OkHttpClient` to download the file:

```
    OkHttpClient client=new OkHttpClient.Builder()
      .addNetworkInterceptor(nightTrain)
      .build();
    Request request=
      new Request.Builder().url(i.getData().toString()).build();
    Response response=client.newCall(request).execute();
    String contentType=response.header("Content-type");
    BufferedSink sink=Okio.buffer(Okio.sink(new File(output.getPath())));

    sink.writeAll(response.body().source());
    sink.close();

    stopForeground(true);
    raiseNotification(contentType, output, null);
```

(from HTTP/OkHttpProgress/app/src/main/java/com/commonsware/android/okhttp3/progress/Downloader.java)

We start off by building an instance of `OkHttpClient` using an `OkHttpClient.Builder`. We will take a closer look at the `addNetworkInterceptor()`

call shortly, as that is where we are hooking in our code to find out about the progress of the HTTP request.

We then:

- Create a `Request` to `GET` our file, using the path supplied to use via `getData()` on the `Intent` passed into `onHandleIntent()`
- Start executing the HTTP operation
- Capture the `Content-type` header, for use when constructing an `ACTION_VIEW` `Intent` to view the downloaded file
- Use Okio (the generic I/O subsystem underlying OkHttp3) to create a `BufferedSink` on our desired output location
- Use Okio to copy all the data from the HTTP response to that output file
- `close()` the output file
- Mark the service as no longer being foreground (via `stopForeground()`)
- Show a download-complete `Notification`

Other than using OkHttp3, little of that is different from the original foreground service sample. Where things start to get interesting is in that `addNetworkInterceptor()` call.

The Interceptor

Interceptors are a way for you to hook into the flow of OkHttp3 processing, such that your code gets invoked for any request made of this `OkHttpClient`. In particular, a network interceptor allows you to get control during the actual network I/O of processing the request.

The OkHttp Git repository contains some sample code that uses a network interceptor to track download progress, and that code forms the foundation of what is shown in this sample.

The `addNetworkInterceptor()` call in `Downloader` is using a local `Interceptor` object, named `nightTrain`:

```
    Interceptor nightTrain=new Interceptor() {
      @Override
      public Response intercept(Chain chain)
        throws IOException {
        Response original=chain.proceed(chain.request());
        Response.Builder b=original
          .newBuilder()
```

```
            .body(
              new ProgressResponseBody(original.body(),
                  progressListener));

          return(b.build());
        }
      };
```

(from HTTP/OkHttpProgress/app/src/main/java/com/commonsware/android/okhttp3/progress/Downloader.java)

An `Interceptor` will be called with a `Chain`, representing the HTTP request and response. The job of the `Interceptor` is three-fold:

1. Call `chain.proceed()` at some point, to kick off the actual HTTP processing
2. Return a `Response` object that will be used as the "real" response of this request
3. Do whatever work the `Interceptor` was designed to do, such as request logging

The `chain.proceed()` call returns the `Response` that would be what OkHttp3 would use in the absence of this `Interceptor`. The `Interceptor` can either return that `Response` or some other `Response`. If you want to monitor the actual network I/O — such as we want to do here, to see how many bytes we have downloaded — the recipe is to use the wrapper pattern and wrap something from the original `Response` in a wrapper that has your business logic.

That is what this sample does. `original.newBuilder()` gives us a `Response.Builder` that is based on the original `Response`. The `body()` of a `Response` is a `ResponseBody` that manages an Okio `Source` object, which handles the actual streaming. We wrap the original `ResponseBody` in a `ProgressResponseBody` that will track our download progress, put that `ProgressResponseBody` into the `Response.Builder`, then return the `Response` that is built by that `Builder`. The net effect is that all calls to the `ResponseBody` will go to our `ProgressResponseBody`.

The ProgressResponseBody

What we *really* want to wrap is the `Source`, an Okio object that is responsible for the real streaming. However, to get there, we have to wrap that original `ResponseBody` in a `ProgressResponseBody`.

ProgressResponseBody itself extends from a ResponseBodyWrapper, which is a ResponseBody that forwards everything onto a wrapped ResponseBody... except for a hook to allow us to wrap the Source:

```
package com.commonsware.android.okhttp3.progress;

import okhttp3.MediaType;
import okhttp3.ResponseBody;
import okio.BufferedSource;
import okio.Okio;
import okio.Source;

// inspired by https://github.com/square/okhttp/blob/master/samples/guide/src/main/java/okhttp3/recipes/
Progress.java

abstract class ResponseBodyWrapper extends ResponseBody {
  abstract Source wrapSource(Source original);

  private final ResponseBody wrapped;
  private BufferedSource buffer;

  ResponseBodyWrapper(ResponseBody wrapped) {
    this.wrapped=wrapped;
  }

  @Override
  public MediaType contentType() {
    return(wrapped.contentType());
  }

  @Override
  public long contentLength() {
    return(wrapped.contentLength());
  }

  @Override
  public BufferedSource source() {
    if (buffer==null) {
      buffer=Okio.buffer(wrapSource(wrapped.source()));
    }

    return(buffer);
  }
}
```

(from HTTP/OkHttpProgress/app/src/main/java/com/commonsware/android/okhttp3/progress/ResponseBodyWrapper.java)

Subclasses of ResponseBodyWrapper need to implement wrapSource() to wrap the Source of the Response.

ProgressResponseBody does just that, wrapping the Source in a subclass of ForwardingSource named ProgressSource:

```
package com.commonsware.android.okhttp3.progress;
```

```
import java.io.IOException;
import okhttp3.ResponseBody;
import okio.Buffer;
import okio.ForwardingSource;
import okio.Source;

// inspired by https://github.com/square/okhttp/blob/master/samples/guide/src/main/java/okhttp3/recipes/
Progress.java

class ProgressResponseBody extends ResponseBodyWrapper {
  private final Listener listener;

  ProgressResponseBody(ResponseBody wrapped, Listener listener) {
    super(wrapped);

    this.listener=listener;
  }

  @Override
  Source wrapSource(Source original) {
    return(new ProgressSource(original, listener));
  }

  class ProgressSource extends ForwardingSource {
    private final Listener listener;
    private long totalRead=0L;

    public ProgressSource(Source delegate, Listener listener) {
      super(delegate);

      this.listener=listener;
    }

    @Override
    public long read(Buffer sink, long byteCount)
      throws IOException {
      long bytesRead=super.read(sink, byteCount);
      boolean done=(bytesRead==-1);

      if (!done) {
        totalRead+=bytesRead;
      }

      listener.onProgressChange(totalRead,
        ProgressResponseBody.this.contentLength(), done);

      return(bytesRead);
    }
  }

  interface Listener {
    void onProgressChange(long bytesRead, long contentLength,
                          boolean done);
  }
}
```

(from HTTP/OkHttpProgress/app/src/main/java/com/commonsware/android/okhttp3/progress/ProgressResponseBody.java)

Our `ProgressSource` does two things:

1. It tracks the total number of bytes that have been read so far
2. Every time that we read more data, we call a `ProgressResponseBody.Listener` with the number of bytes that have been read so far, the known content length of the stream, and whether we are now done reading from the stream

Updating the Notification

Back in `Downloader`, the `nightTrain` passed in a `progressListener` to the `ProgressResponseBody` constructor. That `progressListener` is an implementation of `ProgressResponseBody.Listener`, where we can actually update our `Notification`:

```
    final ProgressResponseBody.Listener progressListener=
      new ProgressResponseBody.Listener() {
        long lastUpdateTime=0L;

        @Override
        public void onProgressChange(long bytesRead,
                                     long contentLength,
                                     boolean done) {
          long now=SystemClock.uptimeMillis();

          if (now-lastUpdateTime>1000) {
            builder.setProgress((int)contentLength,
              (int)bytesRead, false);
            mgr.notify(FOREGROUND_ID, builder.build());
            lastUpdateTime=now;
          }
        }
      };
```

(from HTTP/OkHttpProgress/app/src/main/java/com/commonsware/android/okhttp3/progress/Downloader.java)

Mostly, what we do is call `setProgress()` on the `NotificationCompat.Builder`. This takes:

- the maximum value of the `ProgressBar`, for which we use the length of the content
- the current progress that we have made, for which we use the number of bytes already downloaded
- whether the `ProgressBar` should be indeterminate, for which we pass `false` to get a `ProgressBar` that shows actual progress

Then, we `build()` a fresh `Notification` from the `Builder` and pass that to `notify()` with the same ID. This will update our existing `Notification`, showing the updated progress.

However, our listener is going to be invoked fairly frequently, so much that we might swamp the system just constantly updating the `Notification`. To help with that, we track when we update the `Notification` and only update it again if a second has passed.

What If We Had an Activity in the Foreground?

You may want to be presenting the progress of the download in two places: the `Notification` and the UI of your application, if a relevant bit of that UI happens to be in the foreground. For example, you might have a fragment that contained the button or action bar item that kicked off the download. So long as that fragment is visible, you might want to have a `ProgressBar` on it and update the progress there.

If you use an event bus, you can have your `ProgressResponseBody.Listener` post an event with the progress of the download. However, that event should include some sort of unique identifier for the download itself, in addition to the progress. That way, only the fragment related to this specific download will show the progress, not similar fragments elsewhere.

The APK edition of this book takes this approach in the Community Theater area, where you can download and watch presentations on Android app development topics ("appinars"). An appinar is a ZIP archive up on a CommonsWare server. When you browse the catalog of appinars and choose one, the screen will either let you download the appinar or play the appinar (if it is already downloaded). The download will use code reminiscent of what you see in the sample app, with the added feature of event bus messages publishing the progress to the rest of the app. However, we only show the download progress on the fragment for the particular appinar that is being downloaded. If, while the download is progressing, you visit other appinar descriptions, we do not want to show the download progress there, as you will think that you are downloading those appinars too. The `Notification` shows the name of the appinar that you are downloading, so it provides built-in context for what appinar the progress pertains to.

Custom Views

When you specify a title and a description for a `Notification`, you are implicitly telling Android to use a stock layout for the structure of the `Notification` object's entry in the notification drawer. However, instead, you can provide Android with the layout to use and its contents, by means of a `RemoteViews`. In other words, by using the same techniques that you use to create app widgets, you can create tailored notification drawer content. Just create the `RemoteViews` and supply it to your `NotificationCompat.Builder` via `setContent()`.

To update the notification tile content, you update your `RemoteViews` in your `Notification` and re-raise the `Notification` via a call to `notify()`. Android will apply your revised `RemoteViews` to the notification drawer content, and the user will see the changed widgets.

The `Notifications/CustomView` sample project is a clone of the `HTTP/OkHttpProgress` shown in the previous section. The difference is that we will use our own custom layout and a `RemoteViews` rather than use the standard `Notification` UI.

The Notification Layout

This sample app has its `minSdkVersion` set to 21, so we only need to worry about providing a layout that looks OK on Android 5.0+ devices. Google dramatically changed the look of notifications with Android 5.0, so a layout that looks good on older devices may not blend in well with newer devices. If you have a need to support a wider range of Android versions, you will want to consider using versioned layout resources (e.g., `res/layout/` for older devices, `res/layout-v21/` for API Level 21+ devices).

But, since this app's scope is limited, we can directly refer to `Theme.Material`-based themes, to get a layout that has elements that resembles the actual notification tile content:

```
<?xml version="1.0" encoding="utf-8"?>
<LinearLayout xmlns:android="http://schemas.android.com/apk/res/android"
  android:layout_width="match_parent"
  android:layout_height="match_parent"
  android:orientation="vertical">

  <TextView
```

```
    android:id="@android:id/title"
    style="@android:style/TextAppearance.Material.Notification.Title"
    android:layout_width="wrap_content"
    android:layout_height="wrap_content"
    android:layout_margin="4dp"
    android:ellipsize="marquee"
    android:singleLine="true" />

  <ProgressBar
    android:id="@android:id/progress"
    style="@android:style/Widget.Material.ProgressBar.Horizontal"
    android:layout_width="match_parent"
    android:layout_height="wrap_content"
    android:layout_margin="4dp"
    android:indeterminate="false" />
</LinearLayout>
```

(from Notifications/CustomView/app/src/main/res/layout/notif_content.xml)

Here, we are just showing a title and a `ProgressBar`. The `TextView` uses `@android:style/TextAppearance.Material.Notification.Title`, which is the same style as is used by the official `Notification` layout. The `ProgressBar` uses `@android:style/Widget.Material.ProgressBar.Horizontal`, also mirroring what you will see in real notifications.

Using the Layout

The new sample's `buildForeground()` method now creates a `RemoteViews` for this layout, fills in the title, and uses that with `NotificationCompat.Builder` and `setContent()`:

```
  private NotificationCompat.Builder buildForeground(
    String filename) {
    NotificationCompat.Builder b=
      new NotificationCompat.Builder(this, CHANNEL_WHATEVER);
    RemoteViews content=new RemoteViews(getPackageName(),
      R.layout.notif_content);

    content.setTextViewText(android.R.id.title, "Downloading: "+filename);

    b.setOngoing(true)
      .setContent(content)
      .setSmallIcon(android.R.drawable.stat_sys_download);

    return(b);
  }
```

(from Notifications/CustomView/app/src/main/java/com/commonsware/android/okhttp3/progress/Downloader.java)

However, `NotificationCompat.Builder` has a write-only API. We cannot get our `RemoteViews` back from that. But, we need the `RemoteViews` to be able to update our progress. So, to that end, we hold onto the actual `Notification` built by the `Builder` in `onHandleIntent()`:

```
      NotificationCompat.Builder builder=
        buildForeground(filename);
      final Notification notif=builder.build();
```

(from Notifications/CustomView/app/src/main/java/com/commonsware/android/okhttp3/progress/Downloader.java)

Then, in our `ProgressResponseBody.Listener`, we get at the `RemoteViews` via the `contentView` `public` field on the `Notification`. We can call a `setProgressBar()` method on the `RemoteViews`, much as we called `setProgress()` on the `NotificationCompat.Builder` in the preceding example:

```
      final ProgressResponseBody.Listener progressListener=
        new ProgressResponseBody.Listener() {
          long lastUpdateTime=0L;

          @Override
          public void onProgressChange(long bytesRead,
                                       long contentLength,
                                       boolean done) {
            long now=SystemClock.uptimeMillis();

            if (now-lastUpdateTime>1000) {
              notif
                .contentView
                .setProgressBar(android.R.id.progress,
                  (int)contentLength, (int)bytesRead, false);
              mgr.notify(FOREGROUND_ID, notif);
              lastUpdateTime=now;
            }
          }
        };
```

(from Notifications/CustomView/app/src/main/java/com/commonsware/android/okhttp3/progress/Downloader.java)

Then, we can `notify()` the `NotificationManager` with the updated `Notification`, causing the `ProgressBar` to advance based on the actual progress made.

The resulting `Notification` shows our `RemoteViews` in action:

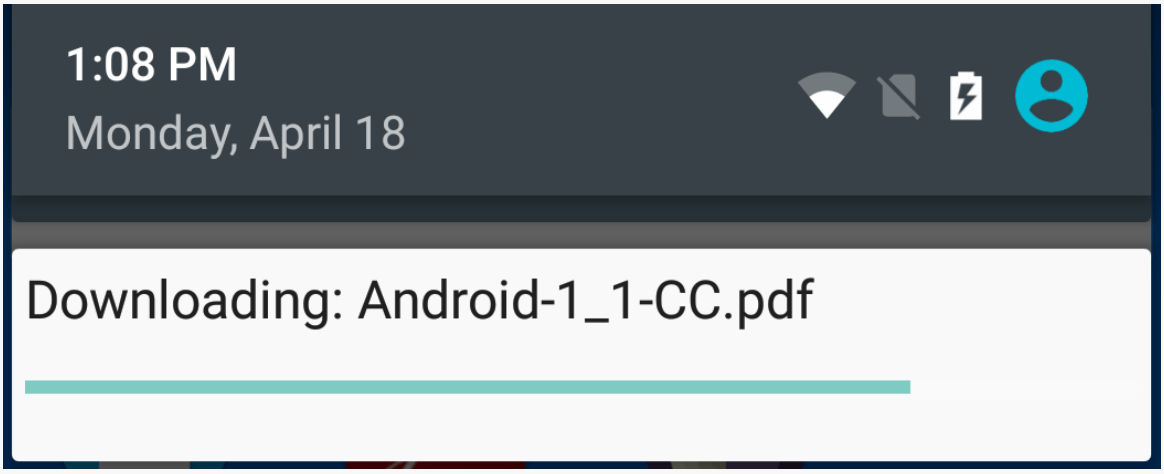

Figure 430: Custom Notification

Styling Custom Views

A custom view for a `Notification` takes over the entire tile in the notification shade. Sometimes, this may be necessary to achieve the developer's objective. Other times, though, while the main content area of the `Notification` might need to be custom, the rest of the "frame" around that content area could be left intact. This would include things like the app's icon, the time the `Notification` was raised, any action buttons below the content, and so forth.

Android 7.0+ offers this via the `Notification.DecoratedCustomViewStyle` and `Notification.DecoratedMediaCustomViewStyle` styles. On your `Builder`, call `setCustomContentView()` with the `RemoteViews` for the content area, plus call `setStyle()`, passing in an instance of `DecoratedCustomViewStyle` or `DecoratedMediaCustomViewStyle`, to gain this effect.

Life After Delete

Most of the time, you do not care about your `Notification` being dismissed by the user from the notification drawer (e.g., pressing the Clear button on Android 1.x/2.x devices). If you do care about the `Notification` being deleted this way, you can supply a `PendingIntent` in the `deleteIntent` data member of the `Notification` — this will be executed when the user gets rid of your `Notification`. Usually, this will be a `getService()` or `getBroadcast()` `PendingIntent`, to have you do something in

the background related to the dismissal. Users are likely to get rather irritated with you if you pop up an activity because they got rid of your `Notification`.

Note that this only works for `Notification` objects that can be cleared. If you have `FLAG_ONGOING_EVENT` set on the `Notification`, it will remain on-screen until *you* get rid of it.

The Mysterious Case of the Missing Number

The `Notification` class has a `number` data member. On Android 1.x and 2.x, setting that data member would cause a number to be super-imposed on top of your icon in the status bar. That data member no longer works as of Android 3.0.

However, `NotificationCompat.Builder` has a `setNumber()` method which *does* work on API Level 11 and higher, though with slightly different behavior. Instead of putting the number on top of your status bar icon, the number will appear in your notification drawer entry. This only works if you do not use `setContent()` with `NotificationCompat.Builder` to define your own notification drawer entry layout — in that case, you could put your own number in wherever you would like.

Notifications and MessagingStyle

Android 7.0 offers a new `MessagingStyle` to the roster of expanded `Notification` styles. This one is designed for a chat-style presentation, where you supply a series of chat messages (person, timestamp, and message), and they are rendered in the `Notification`. It is designed to be used with the `RemoteInput` option described earlier in this chapter, for the user to be able to participate in a chat without having to open up your activity.

As usual, there are two implementations of `MessagingStyle`:

- `Notification.MessagingStyle` is part of Android 7.0's SDK and requires you to build for Android 7.0 (e.g., `compileSdkVersion 24`)
- `NotificationCompat.MessagingStyle`, from the Android Support libraries, for backwards compatibility

The `Notifications/Messaging` sample project demonstrates the use of the latter, along with the `RemoteInput` support from earlier.

While the RemoteInput and MessagingStyle from NotificationCompat will build and run on older devices, they do not work especially well. You simply get a do-nothing Notification action for the RemoteInput and no real context around the messages. As such, you only want to use these options on Android 7.0 devices, gracefully degrading to some other experience on older devices.

Also note that the NotificationCompat.MessagingStyle is from the v24 generation of the Android Support libraries. In this case, we are using 25.0.0 of support-compat, which contains NotificationCompat and NotificationManagerCompat.

```
apply plugin: 'com.android.application'

dependencies {
    implementation 'com.android.support:support-compat:26.1.0'
}

android {
    compileSdkVersion 26
    buildToolsVersion '26.0.2'

    defaultConfig {
        minSdkVersion 15
        targetSdkVersion 26
        versionCode 1
        versionName "1.0"
    }
}
```

(from Notifications/Messaging/app/build.gradle)

As with the RemoteInput sample, the MainActivity is here just to provide us with an easy way to get the Notification to appear on the screen. In this case, though, all we do is use NotificationManagerCompat to show a Notification built elsewhere:

```
package com.commonsware.android.messaging;

import android.app.Activity;
import android.os.Bundle;
import android.support.v4.app.NotificationManagerCompat;

public class MainActivity extends Activity {
  @Override
  public void onCreate(Bundle savedInstanceState) {
    super.onCreate(savedInstanceState);
```

```
    NotificationManagerCompat
      .from(this)
      .notify(RemoteInputReceiver.NOTIFY_ID,
        RemoteInputReceiver.buildNotification(this).build());

    finish();
  }
}
```

(from Notifications/Messaging/app/src/main/java/com/commonsware/android/messaging/MainActivity.java)

Our `RemoteInputReceiver` is more complex as a result:

```
package com.commonsware.android.messaging;

import android.app.NotificationChannel;
import android.app.NotificationManager;
import android.app.PendingIntent;
import android.content.BroadcastReceiver;
import android.content.Context;
import android.content.Intent;
import android.os.Build;
import android.os.Bundle;
import android.support.v4.app.NotificationCompat;
import android.support.v4.app.NotificationManagerCompat;
import android.support.v4.app.RemoteInput;
import android.util.Log;
import java.util.Stack;

public class RemoteInputReceiver extends BroadcastReceiver {
  private static final String CHANNEL_WHATEVER="channel_whatever";
  static final int NOTIFY_ID=1337;
  static final String EXTRA_INPUT="input";
  static final Stack<Message> MESSAGES=new Stack<>();
  static final long INITIAL_TIMESTAMP=System.currentTimeMillis();

  static NotificationCompat.Builder buildNotification(Context ctxt) {
    NotificationManager mgr=
      (NotificationManager)ctxt.getSystemService(Context.NOTIFICATION_SERVICE);

    if (Build.VERSION.SDK_INT>=Build.VERSION_CODES.O &&
      mgr.getNotificationChannel(CHANNEL_WHATEVER)==null) {
      mgr.createNotificationChannel(new NotificationChannel(CHANNEL_WHATEVER,
        "Whatever", NotificationManager.IMPORTANCE_DEFAULT));
    }

    Intent i=new Intent(ctxt, RemoteInputReceiver.class);
    PendingIntent pi=
      PendingIntent.getBroadcast(ctxt, 0, i, PendingIntent.FLAG_UPDATE_CURRENT);

    RemoteInput remoteInput=
      new RemoteInput.Builder(RemoteInputReceiver.EXTRA_INPUT)
        .setLabel(ctxt.getString(R.string.talk))
        .build();

    NotificationCompat.Action remoteAction=
      new NotificationCompat.Action.Builder(
```

```
        android.R.drawable.ic_btn_speak_now,
        ctxt.getString(R.string.talk),
        pi).addRemoteInput(remoteInput).build();

    NotificationCompat.MessagingStyle style=
      new NotificationCompat.MessagingStyle("Me")
        .setConversationTitle("A Fake Chat");

    style.addMessage("Want to chat?", INITIAL_TIMESTAMP, "Somebody");

    for (Message msg : MESSAGES) {
      style.addMessage(msg.text, msg.timestamp,
        style.getUserDisplayName());
    }

    NotificationCompat.Builder builder=
      new NotificationCompat.Builder(ctxt, CHANNEL_WHATEVER)
        .setSmallIcon(
          android.R.drawable.stat_sys_download_done)
        .setContentTitle(ctxt.getString(R.string.title))
        .setStyle(style)
        .addAction(remoteAction);

    return(builder);
  }

  @Override
  public void onReceive(Context ctxt, Intent i) {
    Bundle input=RemoteInput.getResultsFromIntent(i);

    if (input!=null) {
      CharSequence text=input.getCharSequence(EXTRA_INPUT);

      if (text!=null) {
        MESSAGES.push(new Message(text));
      }
      else {
        Log.e(getClass().getSimpleName(), "No voice response speech");
      }
    }
    else {
      Log.e(getClass().getSimpleName(), "No voice response Bundle");
    }

    NotificationManagerCompat
      .from(ctxt)
      .notify(RemoteInputReceiver.NOTIFY_ID,
        buildNotification(ctxt).build());
  }

  private static class Message {
    final CharSequence text;
    final long timestamp;

    Message(CharSequence text) {
      this.text=text;
      timestamp=System.currentTimeMillis();
    }
  }
}
```

(from Notifications/Messaging/app/src/main/java/com/commonsware/android/messaging/RemoteInputReceiver.java)

For the `MessagingStyle`, we need messages. In a production app, this would be part of your app's data model, probably saved in a file or database somewhere, with an in-memory cache for speed. In this sample app, we just have a static `MESSAGES Stack`, for our messages. Initially, this `Stack` is empty, but we will eventually fill in `Message` objects, each of which has text and a timestamp. Since this is a sample app, and all `Message` objects will come from our app's user, we do not need `Message` to track the sender of the message — a real chat-style app would need this, in all likelihood.

The `buildNotification()` method starts off with the same basic code shown in the `RemoteInput` sample. But then, mid-way through the method, we build up the `MessagingStyle`:

```
    NotificationCompat.MessagingStyle style=
      new NotificationCompat.MessagingStyle("Me")
        .setConversationTitle("A Fake Chat");

    style.addMessage("Want to chat?", INITIAL_TIMESTAMP, "Somebody");

    for (Message msg : MESSAGES) {
      style.addMessage(msg.text, msg.timestamp,
        style.getUserDisplayName());
    }
```

(from Notifications/Messaging/app/src/main/java/com/commonsware/android/messaging/RemoteInputReceiver.java)

The parameter to the `MessagingStyle` constructor is the name associated with the user of this app. That name will appear alongside messages that come from this user. A `MessagingStyle` can have a title, set via `setConversationTitle()`, to provide some context for the chat transcript.

We then add one fake message, ostensibly from the chat partner, via the `addMessage()` method. The version we use here takes the text, timestamp, and name of the other party to use in the message.

Then, if there are messages in the `MESSAGES` stack, we add those to the chat transcript as well. Note that our third parameter is `style.getUserDisplayName()`, which returns the value that we passed into the `MessagingStyle` constructor. We could get the same effect by passing `null` for the third parameter.

That `MessagingStyle` then is attached to the `NotificationCompat.Builder` via `setStyle()`.

At the outset, since `MESSAGES` is empty, we get a single message from "Somebody":

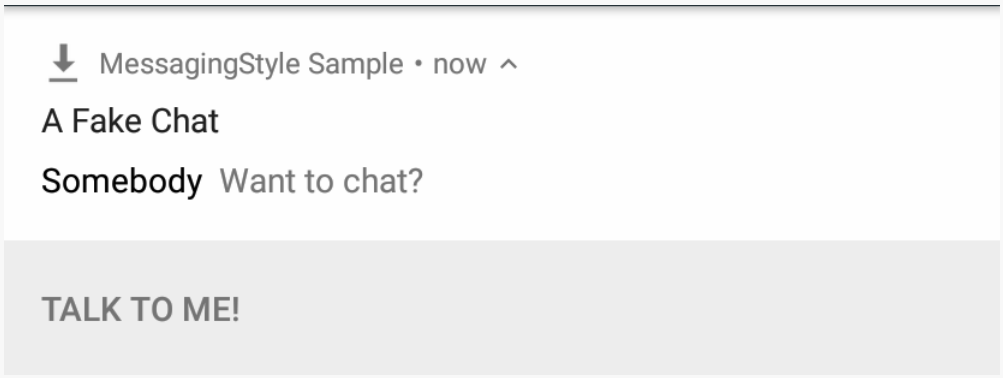

Figure 431: Messaging Demo Notification, As Initially Launched

If the user taps "Talk to Me", types in a message, and clicks the send button, our `RemoteInputReceiver` will take that text, put it in a `Message`, push that `Message` into the `MESSAGES` `Stack`, then update the `Notification` with the new transcript:

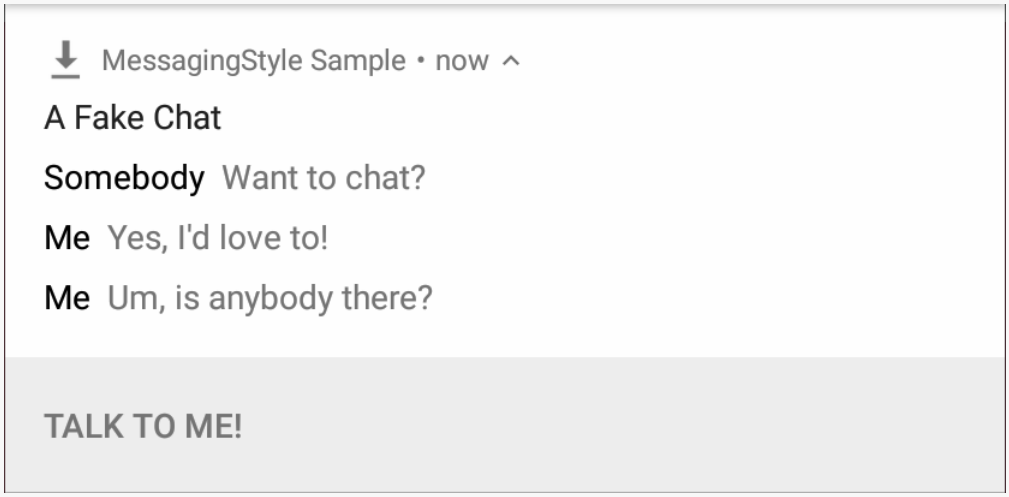

Figure 432: Messaging Demo Notification, After Two Replies

The timestamp does not show up; it is unclear how that is used by Android.

Changes in API Level 23

Historically, while we could supply a "large bitmap" (e.g., photo or avatar) to a `Notification` for use in the tile in the notification tray as a `Bitmap`, the "small icon"

used for the status bar always had to be a resource in our app. This was aggravating for developers that wanted to tailor the small icon, such as a weather app showing the current temperature. Now, we can supply an `Icon` object, which can wrap a drawable resource, a `Uri` to a `ContentProvider`, a `byte` array of encoded bitmap data, a `Bitmap`, or a path to a local PNG or JPEG file. Any of those can be used for the small icon, offering greater flexibility. That being said, please do bear in mind that the small icon is small (i.e., tiny changes may not be noticeable) and that ideally it should adhere to the platform aesthetic for notification icons (i.e., do not use a photo).

The user can now disable our heads-up notifications, if the user finds them irritating. We can get an idea of what the user's chosen notification policies are via `getCurrentInterruptionFilter()` and `getNotificationPolicy()`, so we have some general sense of what the user is and is not expecting to see in terms of notifications.

And, at long last, we can find out all of our active notifications, via a `getActiveNotifications()` method. This will include any notification that is visible to the user (i.e., the user has not dismissed it and we have not gotten rid of it via `cancel()`).

Sounds and Android 7.0

You can put a custom ringtone on a `Notification`, via methods like `setSound()` on `NotificationCompat.Builder`. This requires a `Uri`. And, unfortunately, your options for that `Uri` are limited:

- `android.resource` `Uri` values are fine, if the sound that you want to play is a raw resource
- `file` `Uri` values will work prior to Android 7.0 and for apps whose `targetSdkVersion` is below 24
- `content` `Uri` values are the preferred solution for sounds that exist as files (e.g., by using `FileProvider`), but they do not work on Android 7.0 without additional work, because Android may not have read access to your content

The best easy solution at the moment, for `content` `Uri` values, is to grant read access to your content to the `com.android.systemui` package, via the `grantUriPermissions()` method on `Context`:

```
grantUriPermission("com.android.systemui", sound,
  Intent.FLAG_GRANT_READ_URI_PERMISSION);
```

(where `sound` is the `Uri` that you want to use with `setSound()`)

However, it is unclear if this is the right package to use for all versions of Android and all possible device manufacturer modifications to Android.

Another possibility is for you to create a read-only `ContentProvider` that can serve your file, perhaps modeled after this book sample, then export that provider. The `FileProvider` from the Android Support library would work, except that it cannot be exported.

Eventually, the author's `StreamProvider` will be updated to support this sort of public read-only pattern.

With luck, future versions of Android (and the `NotificationCompat` backport) will address this more formally.

Auto-Timeout

In Android 8.0+ can now provide a time when the notification should be automatically deleted, as if the user had cleared it personally. This is good for notifications whose value declines a lot after a particular point in time.

To use this, call `setTimeoutAfter()` on the `NotificationCompat.Builder`, supplying a duration in milliseconds:

```
public void raiseCoins(View view) {
  Notification n=new NotificationCompat.Builder(MainActivity.this, CHANNEL_COINS)
    .setContentTitle(getString(R.string.notif_coins_title))
    .setContentText(getString(R.string.notif_coins_text))
    .setSmallIcon(android.R.drawable.stat_sys_warning)
    .setTimeoutAfter(5000)
    .build();

  mgr.notify(NOTIF_ID_COINS, n);
```

(from Notifications/Channels/app/src/main/java/com/commonsware/android/notify/channel/MainActivity.java)

Here, we set the notification to time out after five seconds. Five seconds would be far too short of an active window for ordinary users, but it allows a developer to see the results more quickly.

Colorized Notifications

Calling both `setColorized(true)` and `setColor()` (with a specific color) on a `NotificationComapat.Builder` indicates that you want the color to be used as a highlight color. For a regular notification, this is used to colorize the title. For other notification styles, this may be used to set the background color. Since you have no control over exactly where this color gets used, using this feature is not a particularly good idea. Also, it will only have a visible effect on Android 8.0+.

Launcher Icon Badge

Depending on the home screen launcher implementation, your notifications *may* display a dot on the home screen launcher icon:

Figure 433: Home Screen Launcher Notification Dot, from Pixel

This will happen by default; you do not need to do anything to make it happen. However, it will only appear on a handful of devices that have a compatible home screen.

You can disable this by calling `setShowBadge(false)` on the `NotificationChannel` when you create it.

For launchers that support badges, a long-press on the launcher icon may show details of the notification:

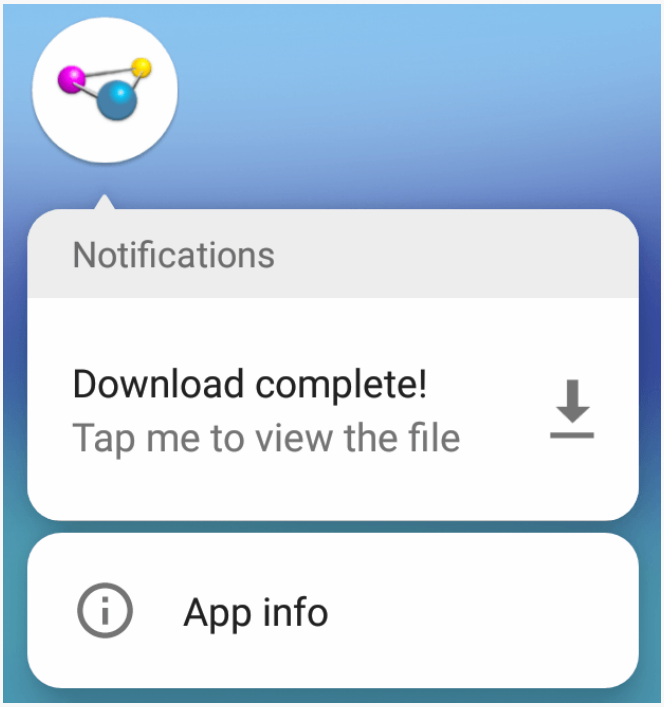

Figure 434: Home Screen Launcher Notification Details, from Pixel

You can control two elements of this, beyond what you would normally configure in the notification itself:

- Call `setBadgeIconType()` on the `NotificationCompat.Builder` to indicate whether the icon should be displayed or not, and whether the small or the large icon will be used
- Call `setNumber()` on the `NotificationCompat.Builder` to offer up a number to show in the details:

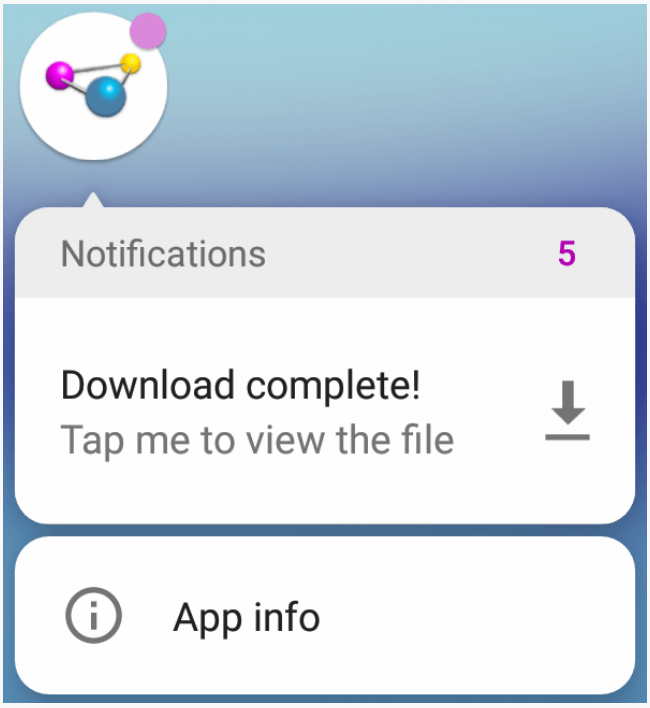

Figure 435: Home Screen Launcher Notification Details With Number, from Pixel

For example, you might use this for an unread message count, if that information is not otherwise present in the notification.

Multi-Window Support

From the standpoint of users, the most visible new capability in Android 7.0 is multi-window support. Now, the user can be working with more than one Android activity at a time, whether from separate apps or — with the assistance of the app — from the same app. This is akin to the proprietary implementations seen in devices from Samsung, LG, and other manufacturers.

The good news — more or less — is that support for multi-window is automatic. You do not need to change anything in your Android app to have your app moved into a portion of the screen, instead of taking up the full screen.

However, you may want to tweak your app to behave better in a multi-window environment.

Prerequisites

Understanding this chapter requires you to have read the core chapters of the book.

A History of Windows

In the beginning, we were happy to have just one app on the screen at a time.

However, as phones got larger, there was increasing interest in having more than one app visible at a time. Some manufacturers handled this via their own “small apps”, such as floating calculator windows.

However, some, such as Samsung and LG, added support for split-screen dual-window environments, where two apps could be run side-by-side. These were proprietary extensions to Android that developers had to opt into.

Other manufacturers, such as Jide, set up alternative versions of Android (e.g., Jide's Remix OS) that supported windows akin to desktop operating systems, with an arbitrary number of overlapping windows. These too were proprietary extensions, unique to those environments.

With Android 7.0, these sorts of capabilities are now part of the core OS, with standardized ways for developers to work with them.

What The User Sees

For most Android devices, the user experience will be what is known as the split-screen view:

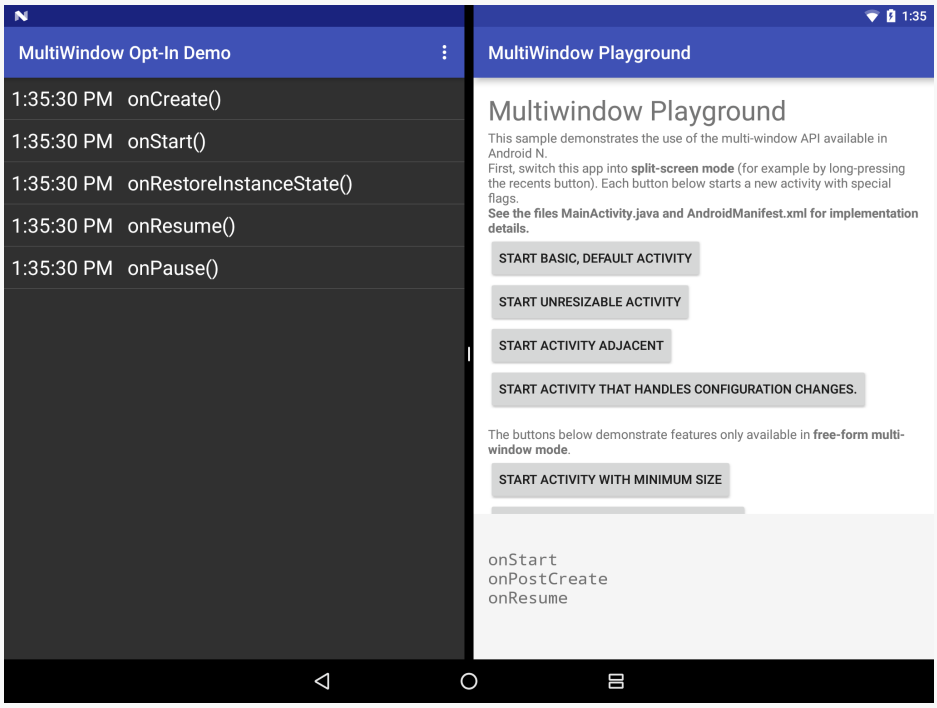

Figure 436: Split-Screen Mode on Nexus 9

The user can enter split-screen mode by long-pressing on the OVERVIEW button (the one that brings up the recent tasks). The existing foreground activity will be put

in one pane, with the overview screen in the other pane, where the user can choose another app.

If the user rotates the screen, the split-screen remains, still splitting along the long axis:

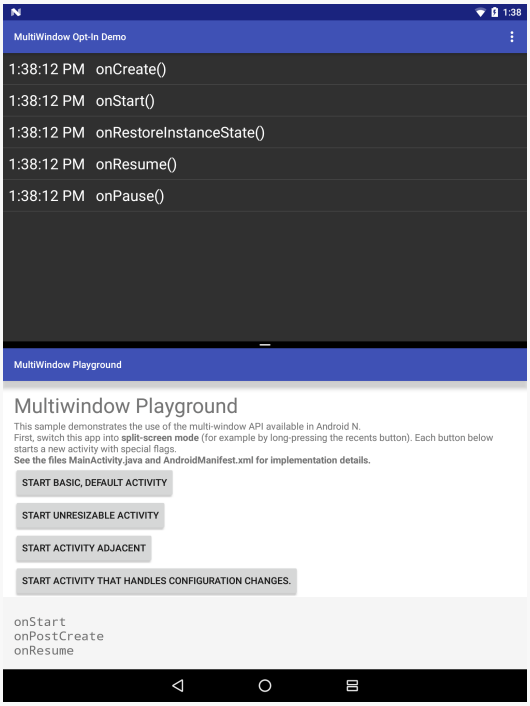

Figure 437: Split-Screen Mode on Nexus 9, Portrait Mode

The divider is movable between three positions, to either equally split the space (default) or to give one pane or the other about two-thirds of the space:

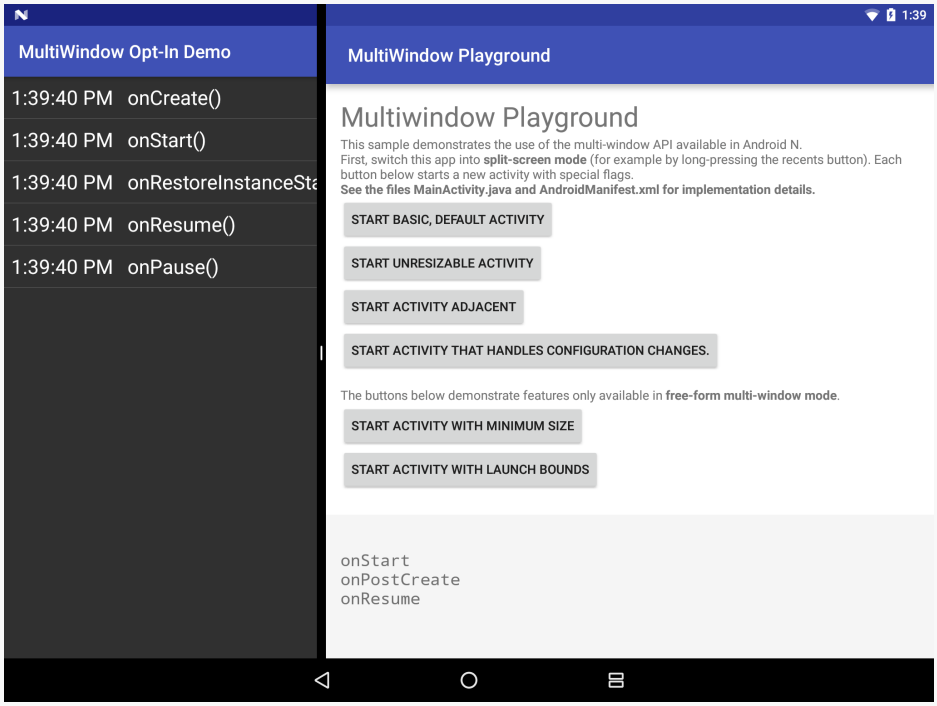

Figure 438: Split-Screen Mode on Nexus 9, After Moving Divider

Android TV devices support a "picture-in-picture" mode instead, where one activity is in a small floating window, overlaying the other activity.

The documentation also describes a "freeform" mode, where Android behaves like a desktop OS with overlapping fully-resizable windows. At the time this paragraph was written (October 2016), no production devices officially support freeform multi-window, though power users have a way of enabling it.

What Your Code Sees

From your activity's standpoint, the fact that it once used most of the screen, and now is only smaller part of a screen, is just a configuration change, no different than orientation changes or other screen size changes (e.g., putting the device in a dock that provides a larger screen).

Whatever activity the user tapped on last is considered to be the foreground activity. Other activities that are visible, such as the activity in the adjacent split-screen pane, will be paused. This is in line with the way Android has always worked:

- if your activity is visible, but not in the foreground, it will be paused (e.g., a system-supplied dialog-themed activity is in the foreground)
- if your activity is no longer visible, it will be stopped

You will want to think through what business logic of your activities belongs in `onStart()`/`onStop()` and what belongs in `onResume()`/`onPause()`. Historically, since being visible but not in the foreground was an uncommon, short-lived state, we did not necessarily have to worry that much about the distinction between "paused" and "stopped". Now the distinction takes on much greater importance.

In split-screen mode, if the user moves the divider, your activity initially will be simply redrawn to adopt the extra space. Once the user lets go of the divider, and it settles on its final position, your activity may undergo a configuration change. Whether you undergo a configuration change seems somewhat random. With luck, this will be more predictable in the future.

If needed, activities and fragments can find out what is going on with respect to multi-window behavior:

- They can call `isInMultiWindowMode()` to find out if they are in multi-window mode presently... in theory
- They can override `onMultiWindowModeChanged()` to find out if the multi-window state changes

There are also variants of these for picture-in-picture mode for Android TV: `isInPictureInPictureMode()` and `onPictureInPictureModeChanged()`. However, picture-in-picture mode is a particular case of multi-window mode. For example, if `isInPictureInPictureMode()` returns `true`, so will `isInMultiWindowMode()`.

However, `isInMultiWindowMode()` is unreliable, apparently by design. Ideally, avoid doing anything specific for when you are in multi-window mode or not.

Also note that, as of Android 8.0, there are two variants of `onMultiWindowModeChanged()`:

- A one-parameter version, taking a `boolean`, which was the original method added in Android 7.0 but is marked as deprecated in Android 8.0
- A two-parameter version, taking a `boolean` and a `Configuration`, added in Android 8.0

In general, if your `minSdkVersion` is 26 or higher, override the two-parameter version. Otherwise, override the one-parameter version.

Opting Out

For various reasons, you may not want your activity to be eligible to be used in some form of multi-window mode. This may disappoint your users, but you may have valid reasons for this decision.

If your `targetSdkVersion` is `N` (or whatever that turns into, probably `24`, when Android 7.0 ships in final form), you can have an `android:resizeableActivity="false"` attribute on a specific `<activity>` element or on the `<application>` element in your manifest. This will tell Android to always give you the full screen, even if the user tries launch your activity into some form of multi-window mode.

If your `targetSdkVersion` is `23` or lower, whether you support multi-window mode is determined by the `android:screenOrientation` attribute (on an `<activity>` or inherited from the `<application>`). A fixed-orientation activity — such as one that is locked to landscape – will not be put into multi-window mode.

Note that if your `targetSdkVersion` is `23` or lower, and you support any orientation (e.g., you do not have `android:screenOrientation`), Android will allow the user to use your activity in multi-window mode. However, a `Toast` will appear, advising the user that your activity is not designed for multi-window mode and there may be compatibility issues. However, this will serve as a note to users that your app is out of date with respect to newer versions of Android, which may not be in your best interests.

Opting In

As noted, Android will allow your activity to be put in multi-window mode by default.

To avoid the aforementioned warning `Toast`, set your `targetSdkVersion` to `N`. Optionally, you can explicitly have `android:resizeableActivity="true"` in the manifest, though this is the default.

Note that not all activities need to support multi-window mode. For example, you might have some general activities that are fine in multi-window mode, plus a video

player that really should be full-screen in landscape. You might put `android:resizeableActivity="false"` on that latter activity, plus have `android:resizeableActivity="true"` on the `<application>` element (for documentation purposes).

If, for some reason, regular multi-window modes are fine, but picture-in-picture will be a problem, you can have `android:supportsPictureInPicture="false"` on an `<activity>`.

Configuring the Layout

You can add a `<layout>` element as a child to your `<activity>` element, to control aspects of how the activity appears on the screen in multi-window mode.

The only facet of `<layout>` that we can use today is the minimal size, represented by `android:minWidth` and `android:minHeight` attributes. These indicates how small you are willing to have your activity be in the stated direction. If the user moves the divider, and the resulting size of your activity is smaller than your requested minimal size, your activity will appear to extend "under" the other pane.

For example, the `MultiWindow/OptIn` sample application has its minimal width set to 3 inches (`480dp`):

```
  <application
    android:allowBackup="false"
    android:icon="@drawable/ic_launcher"
    android:label="@string/app_name"
    android:resizeableActivity="true"
    android:theme="@style/Theme.Apptheme">
    <activity
      android:name="MainActivity">
      <intent-filter>
        <action android:name="android.intent.action.MAIN" />

        <category android:name="android.intent.category.LAUNCHER" />
      </intent-filter>
      <layout android:minWidth="480dp" />
    </activity>
  </application>

</manifest>
```

(from MultiWindow/OptIn/app/src/main/AndroidManifest.xml)

When positioned on the left of the split-screen, with a size less than 3 inches, the activity "extends beneath" the right pane:

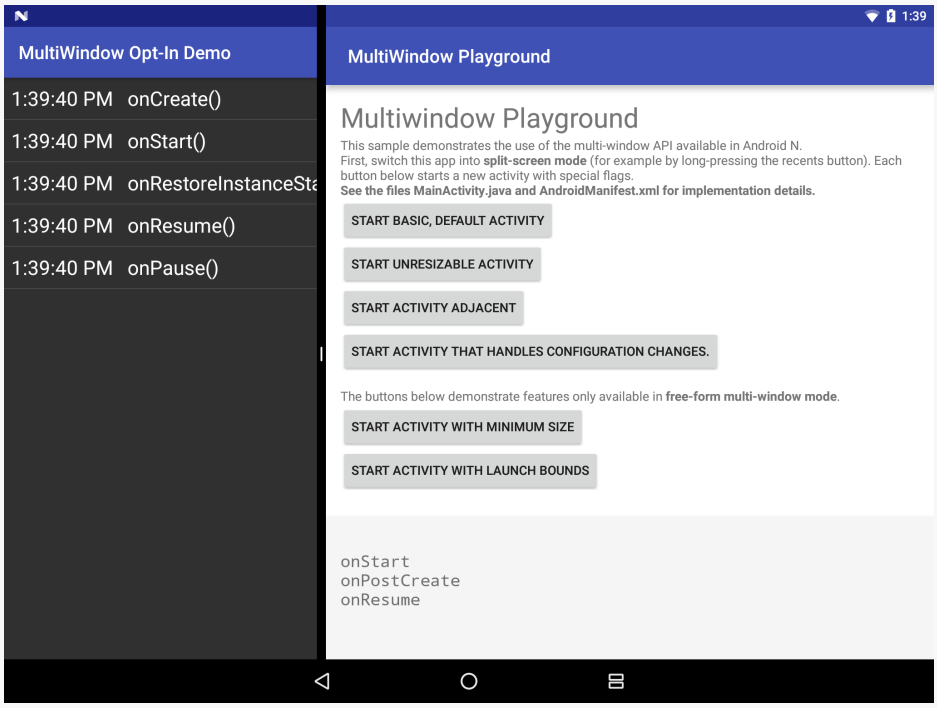

Figure 439: 3-Inch Minimum Size on Left of Split-Screen

The `OptIn` sample app has a `ListView` showing the events received in the lifetime of this activity instance, so you can see the effect of tapping on one activity versus the other in the split-screen mode.

Also, the other activity shown in these screenshots is Google's official multi-window sample app.

For freeform multi-window mode, you also have:

- `android:defaultWidth` and `android:defaultHeight`, to supply a suggested size for your window (as a dimension or as a fraction of the screen size), and
- `android:gravity`, which works like the equivalent widget attribute, suggesting where on the screen your window should be opened

Avoiding Stutter

Since resizing an activity in multi-window mode may cause a configuration change, it is very important for you to handle configuration changes quickly:

- For small bits of data that can be put in a `Bundle`, use the saved instance state `Bundle`, so that your new activity (and fragments) can not only rapidly handle these configuration changes but also handle other scenarios, such as your process being terminated while in the background.
- For larger chunks of data, or data that cannot be put into a `Bundle`, use a retained fragment or a process-level cache. Be careful with the latter technique, though, so that you do not consume too much heap space.

What you want to avoid, if at all possible, is having to do I/O of any form due to a configuration change.

In addition, while the user is resizing your activity, it is simply being redrawn using its current UI, pending completion of the resize (at which point, a configuration change may occur). The more work you do to render the UI, the more work that needs to be done to redraw the UI while the user is resizing, and the more likely that it is that the user will perceive some jank. Possible problem areas include:

- Having hundreds of widgets in your activity
- Having custom widgets that are expensive to redraw
- Triggering some sort of controller-style logic due to a redraw that in turn triggers more serious work (e.g., "we want to log every time the widget gets drawn to a file")

In a pinch, you can optimize certain configuration changes, overriding the default activity destroy-and-recreate cycle, via `android:configChanges`. On the plus side, you can try to make fine-grained changes to your UI and react more responsively. However, *this is an optimization*, not a replacement for proper state management (e.g., saved instance state `Bundle`), as state management is for more than configuration changes.

If you wish to use `android:configChanges` to opt out of automatic handling of certain configuration changes, the ones of relevance for multi-window are:

- `screenSize`
- `smallestScreenSize`

- `screenLayout`
- `orientation`

If you have not used this technique before, you can read more about it in the chapter on configuration changes.

Managing the Background

While the user is resizing the window, Android does not attempt to re-render your UI. Instead, if the window is being shrunk, your existing UI is clipped. If the window is being expanded, a background is shown over the new area. Only once the resize is done does Android perform the configuration change and re-render your UI.

The `android:windowBackground` and `android:windowBackgroundFallback` theme attributes control what that background looks like. You may wish to set `android:windowBackground` in your app's theme to a value that matches your natural window background, so there is a seamless transition between your regular background and the new background added by Android during the resize operation.

How Low Can You Go?

The smallest window size in split-screen mode is 220dp. Your activity should aim to support a width or height of 220dp for maximum compatibility. Using `android:minWidth` and `android:minHeight` will allow your activity to support those small sizes by having your UI be clipped, but this is not an ideal user experience. Rely on `android:minWidth` and `android:minHeight` only for cases where you have no good way of supporting 220dp directly.

It is unclear whether this 220dp minimum also holds for freeform or picture-in-picture multi-window mode.

Handling the Screen Size Transition

Suppose your activity launches in a window size that, based on your layout rules, pulls in a phone-sized layout resource. Now, the user resizes your window, and the resulting size would pull in a tablet-sized layout resource.

Assuming that you are handling all of this properly via the configuration change, technically your activity should work just fine. But from the user's standpoint, it may

result in a jarring transition, if the UI for one screen size is significantly different from the UI for another screen size.

You sometimes see this with Web sites. Some sites apply their site designs based solely on the size of the browser viewport, so they are not dependent upon flaky ways of detecting whether the browser is coming from a mobile device or not. If the viewport is small enough, the page's CSS renders a mobile-friendly UI; larger viewports result in more of a desktop feel. However, if this is based on CSS, resizing a desktop browser window to be small causes the Web page to dynamically shift from desktop to mobile mode, or vice versa. This puts some stress on the Web page design, so that the design not only works statically (i.e., a small rendition works well on mobile) but also dynamically (i.e., the user does not get too confused when the Web page transitions from one set of CSS rules to another).

We will wind up with the same problem in multi-window on Android, as the user resizes windows past our natural transition points.

Ideally, your app uses one UI for everything from small phones (or small windows in multi-window) to large tablets (or large windows in multi-window), regardless of window orientation. Few UI designs work well this way. And since you cannot reliably determine whether or not you are in multi-window mode via `isInMultiWindowMode()`, you cannot reliably treat that as a separate case.

As such, the community will eventually need to evolve some patterns for handling this scenario.

Parallel Processing

Normally, multi-window is for multiple apps. For example, the user might be watching a video in one pane while taking notes in another.

However, there will be cases where it might help the user to have two activities of yours be in the panes of the split-screen mode. Or, there may be cases where users want to launch some content of yours into a separate window in freeform mode.

To do this, you can add `FLAG_ACTIVITY_LAUNCH_ADJACENT` to the `Intent` that starts up another activity. If the device is in some form of multi-window mode, this serves as a hint that you want this new activity to be in a different pane or window than is the current activity. If the device is *not* in multi-window mode, adding this flag has no effect — you cannot force a device into multi-window mode.

Because this is only conditionally available, you will want to set up your UI to reflect that fact. Possible strategies include:

- Only offering a "start in a new pane/window" option if `isInMultiWindowMode()` returns `true`, or toggling its availability in `onMultiWindowChanged()`
- Always having the option to start the activity in a new pane or window, but if `isInMultiWindowMode()` returns `false` at that point, show a dialog or `Snackbar` or something to point out that the user has to set up multi-window mode first

However, the two activities (e.g., the ones in each pane of split-screen) need to be part of separate tasks. The recipe for doing this is to not only use `FLAG_ACTIVITY_LAUNCH_ADJACENT`, but also `FLAG_ACTIVITY_NEW_TASK` and `FLAG_ACTIVITY_MULTIPLE_TASK`.

For example, `MainActivity` in the `OptIn` sample app has an overflow menu with a "Clone" menu item. This opens a second instance of `MainActivity` into the other split-screen pane:

```
@Override
public boolean onOptionsItemSelected(MenuItem item) {
  if (item.getItemId()==R.id.clone) {
    Intent i=
      new Intent(this, MainActivity.class)
        .setFlags(Intent.FLAG_ACTIVITY_LAUNCH_ADJACENT |
          Intent.FLAG_ACTIVITY_NEW_TASK |
          Intent.FLAG_ACTIVITY_MULTIPLE_TASK);

    startActivity(i);
    return(true);
  }

  return(super.onOptionsItemSelected(item));
}
```

(from MultiWindow/OptIn/app/src/main/java/com/commonsware/android/multiwindow/MainActivity.java)

Note that the `Intent` gets all three of the aforementioned flags: `FLAG_ACTIVITY_LAUNCH_ADJACENT`, `FLAG_ACTIVITY_NEW_TASK`, and `FLAG_ACTIVITY_MULTIPLE_TASK`.

The chapter on consuming documents using the Storage Access Framework profiles a `TinyTextEditor` sample app that further demonstrates how to open a separate

window from an existing one. In this case, it will be to move a text editor from a tab in one activity into a separate activity in its own window.

You also have the option of using the two-parameter `startActivity()` that takes a `Bundle`, building that `Bundle` using the `ActivityOptions` class. On `ActivityOptions`, there is `setLaunchBounds()`, to indicate where on the screen the new task's window should appear. The parameter to `setLaunchBounds()` is either a `Rect` (providing that size/location in screen coordinates) or `null` (indicating that the new task's window should occupy the full screen).

Split-Screen, HOME, and Your Activity

We are used to the notion that when the user presses HOME, we are called with `onStop()`. In fact, `onStop()` is even more important than before with Android 7.0, as our activities will be paused (but not stopped) a lot more with multi-window. So, whereas we might have used `onResume()` and `onPause()` for setting up and tearing down foreground work, we might now switch to `onStart()` and `onStop()`.

However, `onStop()` is not always called when the user presses HOME.

If the device is in normal, non-split-screen mode, and the user presses HOME, your foreground activity moves to the background, and `onStop()` is called.

If the device is in split-screen mode, and your activity is in the bottom or right pane (depending on device orientation), and the user presses HOME, your activity is stopped, so you get an `onStop()` call. Visually, the activity animates off-screen fully, and if the user presses the RECENTS button, the pane you had been occupying is replaced with the recent-tasks list.

But, if your activity is in the top or left pane of split-screen, and the user presses HOME, **your activity is not stopped**.

Unfortunately, we are not given any sort of callback or other indication that this has occurred. The theory is that the device will be in this "transient home" state for a short period of time, but that is not guaranteed.

For many activities, there is no real problem, but if your activity is holding a wakelock (e.g., you are using `android:keepScreenOn` or `setKeepScreenOn()`), you are not given an opportunity to release that wakelock, so as long as the device stays in this state, you drain the battery.

For something like a wakelock, you could release that in `onPause()`, while continuing to do the "real work" of the activity until `onStop()`. That is not ideal — the user might be intentionally watching the video in split-screen and want the screen to stay on. However, until we get some means of identifying this state, our options are limited.

Split-Screen and Orientations

If an activity of yours is in the foreground, and the user enters into split-screen mode, your activity will undergo a configuration change. We tend to focus on the fact that the amount of screen space is cut in half. However, in addition, your orientation is likely to change, as half the screen probably has the opposite orientation from the full screen.

As a result, if you have resources, such as layouts, that are orientation-dependent, as the user flips between split-screen and normal modes, your activity will change orientations. This may even occur if the user drags the divider between the split-screen panes, depending on the aspect ratio of the device screen.

From a programming standpoint, this should not be a problem, as there are many more common ways for a device to change orientation (e.g., user rotates the device). However, the user might not expect a significant layout change based solely on entering or exiting split-screen mode, whereas they may be more comfortable with such a change when rotating the screen.

Furthermore, freeform multi-window mode allows the user to arbitrarily resize the window. In that case, the user might switch orientations by resizing the window.

Aim to minimize orientation-dependent resources. Where you need them, try to make the transition between orientations fairly gentle, so the user does not have an adverse reaction to seeing your UI shift on the fly.

Forcing Your App Into Multi-Window/Multi-Instance

Android 7.0 started shipping in August 2016. By September 2016, apps were appearing on the Play Store that allow users to do what some bloggers think is launch multiple instances of an app.

In reality, they launch multiple instances of your launcher activity in separate panes of a split-screen multi-window environment. So, for example, you could have two

instances of Google's News and Weather up side-by-side, even though the app does not directly support this:

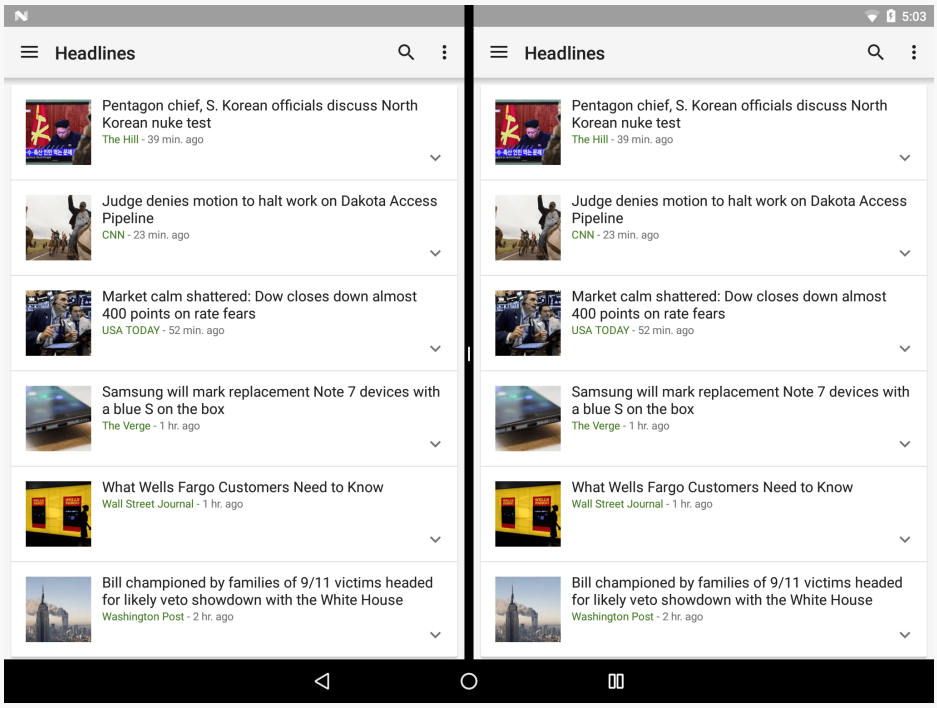

Figure 440: Pair of "News and Weather" Activities

This does not require (much) devious hacking, and it is very possible that we will start seeing device manufacturers offer this sort of capability built into their Android 7.0+ devices.

To understand what's going on, let's examine the `Introspection/Sidecar` sample application. This sample application allows the user to add a custom tile to the quick-settings area of the notification shade. When this Sidecar tile is tapped, a user-specified activity will launch into one of the panes of the split-screen mode. And, as a bonus, if the activity tries blocking split-screen operation via `android:resizeableActivity="false"`, the Sidecar gets around that. The net effect is that any Sidecar user can get two instances of a launcher activity side-by-side... at least, for most apps. For example, the screenshot shown above was set up via Sidecar.

Using Sidecar

Sidecar is not really a production-ready app.

That being said, if you want to play around with this, run and install the app on an Android 7.0+ device. You will be greeted by an activity that shows a list of candidate activities for the Sidecar tile to open. Tap on one. The activity will vanish, showing a "Saved!" `Toast`.

Then, open the notification shade all the way and click "Edit" in the quick-settings area. You should see a "Sidecar" tile that you can drag into the quick-settings area:

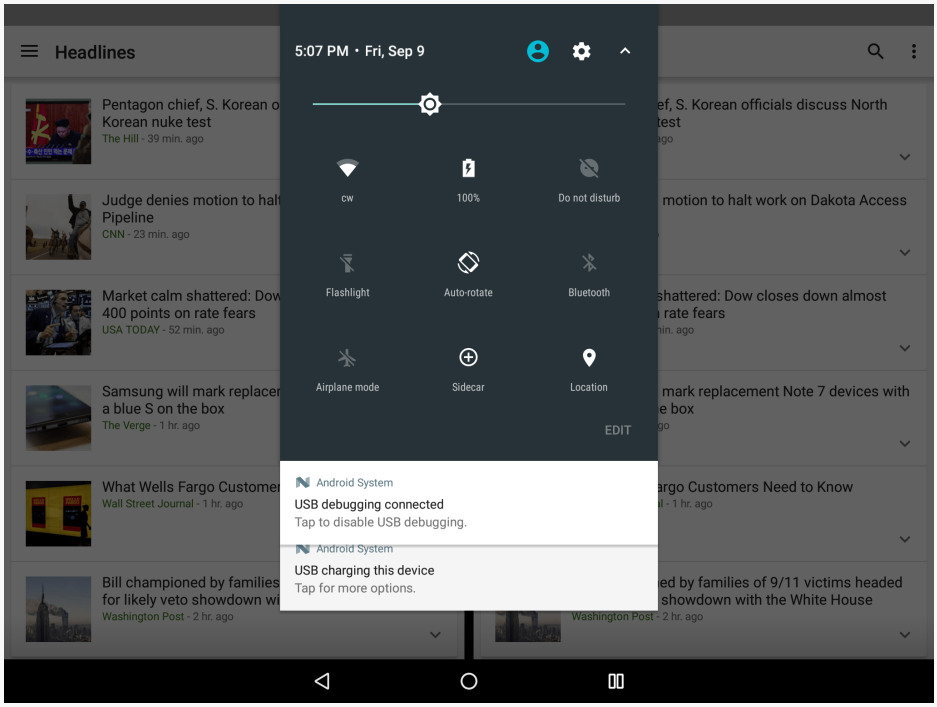

Figure 441: Quick Settings, Showing Sidecar Tile

At this point, if you enter into multi-window mode, then open the notification shade and tap on the Sidecar tile, it will launch the activity you chose into one of the available windows. In mobile device split-screen mode, usually the Sidecar-launched activity will appear in the top or left pane. This will happen even if you have another instance of that same activity in the opposite pane.

Choosing the Activity

Sidecar's `MainActivity` is a near-clone of the `Launchalot` activity profiled elsewhere in the book. It uses `PackageManager` and `queryIntentActivities()` to find all activities that have the `ACTION_MAIN`/`CATEGORY_LAUNCHER` `<intent-filter>`, sorts them alphabetically, and displays them in a `ListView`. The differences here are the

filtering performed in Sidecar and what happens when the user taps on a `ListView` row.

In `Launchalot`, the entire roster of launchable activities is shown in the `ListView`. In Sidecar's `MainActivity`, only a subset are shown, specifically rejecting those whose `android:launchMode` is set to `singleInstance` or `singleTask`:

```
@Override
public void onCreate(Bundle savedInstanceState) {
  super.onCreate(savedInstanceState);

  PackageManager pm=getPackageManager();
  Intent main=new Intent(Intent.ACTION_MAIN, null);

  main.addCategory(Intent.CATEGORY_LAUNCHER);

  List<ResolveInfo> launchables=pm.queryIntentActivities(main, 0);
  List<ResolveInfo> filtered=new ArrayList<>();

  for (ResolveInfo launchable : launchables) {
    int launchMode=launchable.activityInfo.launchMode;

    if (launchMode!=ActivityInfo.LAUNCH_SINGLE_INSTANCE &&
      launchMode!=ActivityInfo.LAUNCH_SINGLE_TASK) {
      filtered.add(launchable);
    }
  }

  Collections.sort(filtered,
                   new ResolveInfo.DisplayNameComparator(pm));

  adapter=new AppAdapter(pm, filtered);
  setListAdapter(adapter);
}
```

(from Introspection/Sidecar/app/src/main/java/com/commonsware/android/sidecar/MainActivity.java)

So, we iterate over the `launchables`, find the `launchMode` for each, and only add the "good" ones to `filtered`. The `filtered` list is what gets shown in the `ListView`.

In `Launchalot`, when the user taps on a row, we create an `Intent` identifying that particular activity, then start up that activity. In Sidecar's `MainActivity`, we save the `ComponentName` identifying the activity to a `SharedPreferences` for later use:

```
@Override
protected void onListItemClick(ListView l, View v,
```

```
                                int position, long id) {
    ResolveInfo launchable=adapter.getItem(position);
    ActivityInfo activity=launchable.activityInfo;
    ComponentName name=new ComponentName(activity.applicationInfo.packageName,
                                         activity.name);

    PreferenceManager
      .getDefaultSharedPreferences(this)
      .edit()
      .putString(SidecarTileService.PREF_TO_LAUNCH,
        name.flattenToString())
      .apply();
    Toast
      .makeText(this, R.string.msg_saved, Toast.LENGTH_LONG)
      .show();
    finish();
  }
```

(from Introspection/Sidecar/app/src/main/java/com/commonsware/android/sidecar/MainActivity.java)

The easiest way to persist a `ComponentName` is to use `flattenToString()`, then persist the `String`. That value can later be used with the `unflattenFromString()` `static` method on `ComponentName` to get back an equivalent `ComponentName`, as will be seen shortly.

So, the job of `MainActivity` is to let the user choose an activity for the Sidecar to launch.

Implementing the TileService

A `TileService` is the Android 7.0+ way to set up tiles that the user can add to the quick-settings area of the notification shade. Full details on how to set up one of those can be found elsewhere in the book. Suffice it to say that we are called with `onClick()` in a subclass of `TileService` — named `SidecarTileService` — when the user taps on our tile. At this point, what we want to do is launch the user's requested activity.

```
package com.commonsware.android.sidecar;

import android.content.ComponentName;
import android.content.Intent;
import android.content.SharedPreferences;
import android.content.pm.ActivityInfo;
import android.preference.PreferenceManager;
import android.service.quicksettings.TileService;
```

```
import android.util.Log;
import android.view.Gravity;
import android.widget.Toast;
import java.lang.reflect.Field;

public class SidecarTileService extends TileService {
  static final String PREF_TO_LAUNCH="toLaunch";

  @Override
  public void onClick() {
    super.onClick();

    SharedPreferences prefs=
      PreferenceManager.getDefaultSharedPreferences(this);
    String cnFlat=prefs.getString(PREF_TO_LAUNCH, null);

    if (cnFlat!=null) {
      ComponentName cn=ComponentName.unflattenFromString(cnFlat);

      try {
        ActivityInfo info=getPackageManager().getActivityInfo(cn, 0);
        Intent i=new Intent().setComponent(cn);
        Field f=ActivityInfo.class.getField("resizeMode");
        Integer resizeMode=(Integer)f.get(info);
        boolean resizeable=(resizeMode.intValue()!=0);

        if (resizeable) {
          i.setFlags(Intent.FLAG_ACTIVITY_NEW_TASK |
            Intent.FLAG_ACTIVITY_MULTIPLE_TASK |
            Intent.FLAG_ACTIVITY_LAUNCH_ADJACENT);

          startActivity(i);
        }
        else {
          Intent taskRoot=
            new Intent(this, TaskRootActivity.class)
              .putExtra(Intent.EXTRA_INTENT, i)
              .setFlags(Intent.FLAG_ACTIVITY_NEW_TASK |
                Intent.FLAG_ACTIVITY_MULTIPLE_TASK |
                Intent.FLAG_ACTIVITY_LAUNCH_ADJACENT);

          startActivity(taskRoot);
        }
      }
      catch (Exception e) {
        Log.e(getClass().getSimpleName(),
          "Exception trying to launch activity", e);
```

```
        toast(R.string.msg_sorry);
      }
    }
    else {
      toast(R.string.msg_choose);
    }
  }

  private void toast(int msg) {
    Toast t=Toast.makeText(this, msg, Toast.LENGTH_LONG);

    t.setGravity(Gravity.END | Gravity.BOTTOM, 32, 32);
    t.show();
  }
}
```

(from Introspection/Sidecar/app/src/main/java/com/commonsware/android/sidecar/SidecarTileService.java)

First, we get our `SharedPreferences` and go looking for our saved `ComponentName`. If that is not found — `getString()` returns `null` for our `PREF_TO_LAUNCH` — then the user has not chosen an activity from the Sidecar `MainActivity`. So, we show a `Toast` to let the user know that they need to choose an activity.

The `setGravity()` call in the `toast()` method shoves our `Toast` over into a lower corner of the screen, to try to get it a bit out of the way of the opened notification shade, as the shade will float over the `Toast`. This approach only works well on wider screens. A production-quality app would do something else here.

Given that we have the `String` representation of the `ComponentName`, we `unflattenFromString()` to get the `ComponentName` back, then put that `ComponentName` into an `Intent`. In most cases, we will then add the multiple-instance flags to the `Intent` (`FLAG_ACTIVITY_NEW_TASK`, `FLAG_ACTIVITY_MULTIPLE_TASK`, and `FLAG_ACTIVITY_LAUNCH_ADJACENT`), then start the activity.

Forcing Activities to Resize

However, if the activity in question has `android:resizeableActivity` set to `false`, we have more work to do.

First, to determine if that is the case for this activity, we have to access a hidden `resizeMode` field inside the `ActivityInfo` object. `ActivityInfo` contains a lot of the information from the `<activity>` element, though not all of it is part of the public Android SDK. Hacking into SDK objects using reflection **is strongly discouraged**,

as there is no guarantee that this field will exist on all devices, courtesy of firmware modifications. Using reflection this way is a great way to get a lot of customer service complaints from users about your app crashing. Regardless, we use the technique here. Based on the `ActivityInfo` source code, `android:resizeableActivity="false"` turns into a `resizeMode` of 0. So, the activity is resizable if `resizeMode` is anything other than 0.

However, as was discussed earlier in this chapter, `android:resizeableActivity` is only honored if your activity is the root of the task. For resizable activities, then, we can just launch the activity directly, but for non-resizable activities, we need to arrange to have *something else* be the task root. To that end, we have a `TaskRootActivity` that simply takes a supplied `Intent` (via an `EXTRA_INTENT` extra), starts an activity using that `Intent`, and finishes:

```
package com.commonsware.android.sidecar;

import android.app.Activity;
import android.content.Intent;
import android.os.Bundle;

public class TaskRootActivity extends Activity {
  @Override
  protected void onCreate(Bundle savedInstanceState) {
    super.onCreate(savedInstanceState);

    startActivity((Intent)getIntent().getParcelableExtra(Intent.EXTRA_INTENT));
    finish();
  }
}
```

(from Introspection/Sidecar/app/src/main/java/com/commonsware/android/sidecar/TaskRootActivity.java)

`TaskRootActivity` is set up in the manifest to have a theme of `Theme.Translucent.NoTitleBar`, so the user will not usually see the activity, just the one that it starts. However, that is sufficient to allow `TaskRootActivity` to decide the resize rules for the task, overriding those of the user's chosen activity.

So, for non-resizable activities, `SidecarTileService` wraps the real `Intent` in one for `TaskRootActivity`, sets the multiple-instance flags, and starts that activity, which in turn starts the real activity in the separate pane.

Breaking the Sidecar

So, what can we learn from Sidecar about these other apps that do this sort of thing?

If your activity is exported — as are launcher activities — then there is little that you can do to stop other apps from launching your activity in a separate task to enable this sort of multi-window/multi-instance behavior. One thing that *does* stop it is to have `android:launchMode` of `singleInstance` or `singleTask`. That at least prevents multiple instances of your activity being launched in parallel, as it overrides the `FLAG_ACTIVITY_NEW_TASK` and `FLAG_ACTIVITY_MULTIPLE_TASK` flags.

Similarly — as we saw earlier in the chapter — there is nothing much that you can do to stop some other app from launching your activity in an existing task, thereby blocking you from controlling whether your activity gets resized.

Ideally, you do not worry much about either of these things, but instead set up your app to be able to work acceptably in these cases. Again, it is well within reason that device manufacturers will start offering this sort of "start another copy of the app" feature to their users. Sidecar, in this respect, can serve as a testbed for how well your app behaves when the user does this sort of thing.

Supporting Legacy Proprietary Multi-Window

As noted earlier in the chapter, some manufacturers experimented with multi-window implementations prior to Google rolling it into Android 7.0. These come in three flavors:

- Some, like Jide's Remix OS, require no developer work. Apps just show up in windows. There might be compatibility concerns, particularly since many Remix OS-powered devices have keyboards and mice. However, there is no up-front requirement to do something to opt into participating in the multi-window experience.
- Some, like Samsung's and LG's, require minor modification of your app's manifest, but no other specific work.
- Some, like SONY's "small apps", require a proprietary SDK, and therefore are somewhat more work. And, in the specific case of SONY's implementation, it has been discontinued.

Since the manifest-only modifications are "low-hanging fruit", giving your users some benefit with little additional work, let's take a look at how to enable those. The

MultiWindow/Legacy sample application is a clone of the `OptIn` sample, adjusted to allow pre-N versions of Android to run the app, and adjusted to support Samsung's and LG's legacy multi-window implementation.

The changes lie purely in the manifest:

```
<?xml version="1.0" encoding="utf-8"?>
<manifest package="com.commonsware.android.multiwindow"
  xmlns:android="http://schemas.android.com/apk/res/android"
  android:versionCode="1"
  android:versionName="1.0">

  <supports-screens
    android:anyDensity="true"
    android:largeScreens="true"
    android:normalScreens="true"
    android:smallScreens="true" />

  <application
    android:allowBackup="false"
    android:icon="@drawable/ic_launcher"
    android:label="@string/app_name"
    android:resizeableActivity="true"
    android:theme="@style/Theme.Apptheme">
    <uses-library
      android:name="com.sec.android.app.multiwindow"
      android:required="false" />

    <meta-data
      android:name="com.sec.android.support.multiwindow"
      android:value="true" />
    <meta-data
      android:name="com.lge.support.SPLIT_WINDOW"
      android:value="true" />

    <activity android:name="MainActivity">
      <intent-filter>
        <action android:name="android.intent.action.MAIN" />

        <category android:name="android.intent.category.LAUNCHER" />
        <category android:name="android.intent.category.MULTIWINDOW_LAUNCHER" />
      </intent-filter>
      <layout android:minWidth="480dp" />
    </activity>
  </application>

</manifest>
```

(from MultiWindow/Legacy/app/src/main/AndroidManifest.xml)

LG requires only one thing: a `<meta-data>` element in the `<application>`, with a name set to `com.lge.support.SPLIT_WINDOW` and a value of `true`. It assumes that your launcher activity (or activities) are suitable for showing in a split screen view.

Samsung requires three things:

- A similar `<meta-data>` element, setting `com.sec.android.support.multiwindow` to `true`
- A `<uses-library>` element, pulling in a firmware-supplied `com.sec.android.app.multiwindow` library, if it is available (`android:required="false"`)
- `<category android:name="android.intent.category.MULTIWINDOW_LAUNCHER" />` added to any `<intent-filter>` of any activity that you want to be able to be launched into the split-screen environment

In this case, we have only one activity, so it now has two `<category>` elements, for `LAUNCHER` and `MULTIWINDOW_LAUNCHER`. Note that while `android.intent.category.MULTIWINDOW_LAUNCHER` has the `android.intent.category` namespace, and not something like `com.sec.android`, `MULTIWINDOW_LAUNCHER` is not part of standard Android.

For supported devices from those manufacturers, your app will be available for split-screen use:

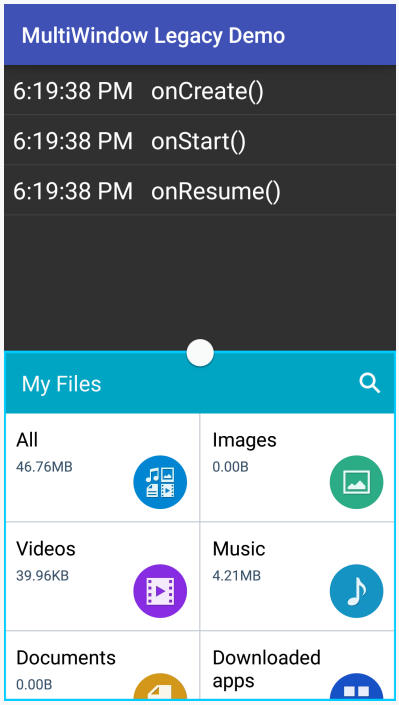

Figure 442: Samsung Legacy Split-Screen Mode

In the case of Samsung, it may also be available as a popup floating window:

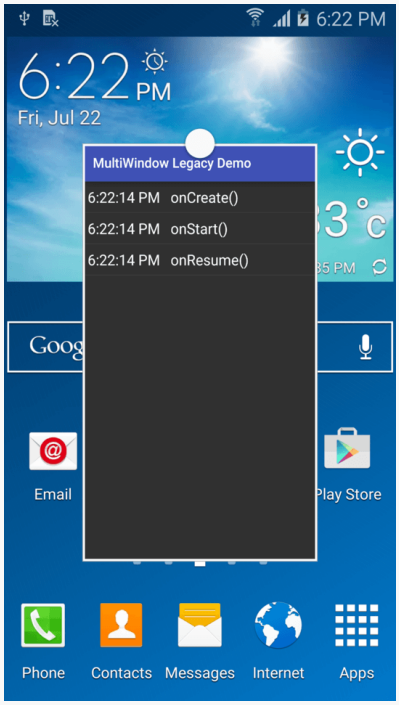

Figure 443: Samsung Legacy Popup Window Mode

One notable difference between these implementations and Android 7.0's multi-window implementation comes with lifecycle events. Android 7.0 will call lifecycle methods on your activity as appropriate during the transition to and from multi-window mode, and sometimes based on size changes of your window. Neither Samsung's nor LG's legacy multi-window does this.

Freeform Multi-Window Mode

Freeform multi-window mode — with desktop-style overlapping resizable windows — is not presently available in an official fashion. However, there are tricks for making it work, even without rooting a device. As a result, some power users will start playing with your app in freeform windows, despite the lack of official support.

Playing with Freeform

If you would like to play with the unofficial freeform multi-window mode, there are a few ways of going about it.

The Taskbar App

There are some apps out on the Play Store and other distribution channels that allow you to launch apps in freeform mode, such as Braden Farmer's Taskbar app.

Freeform support requires you to go into the "Developer options" area of the Settings app and enable "Force activities to be resizable":

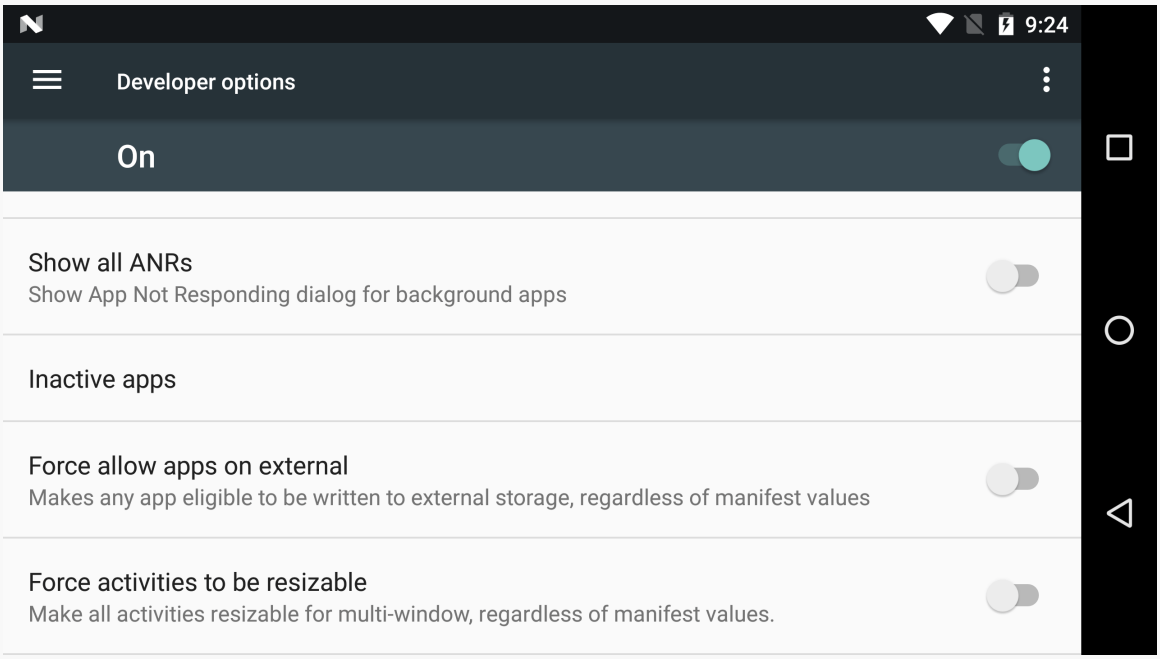

Figure 444: Resizable Windows Developer Setting

If you allow Taskbar to be your home screen, it can launch freeform windows reliably. If you use Taskbar solely as a floating launcher bar – the default — it can launch freeform windows from the overview screen (a.k.a., recent-tasks list) or the home screen, but not elsewhere, and occasionally there will be hiccups where the activity will be launched normally (not freeform).

The adb Setting

If you prefer, you can enable freeform multi-window mode for your device or emulator via:

```
adb shell settings put global enable_freeform_support 1
```

Then, after a reboot, when you visit the overview screen, you will see a window-inset icon in the title bar of the overview cards:

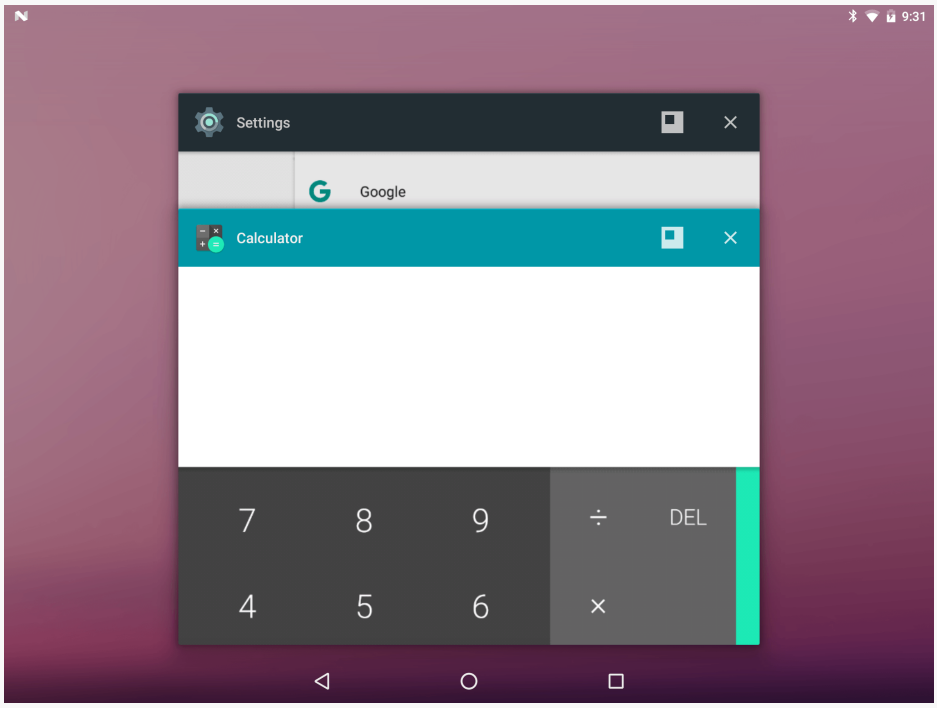

Figure 445: Overview Screen, Showing Freeform Title Bar Icons

Tapping that freeform-window icon will open that particular task in a freeform window:

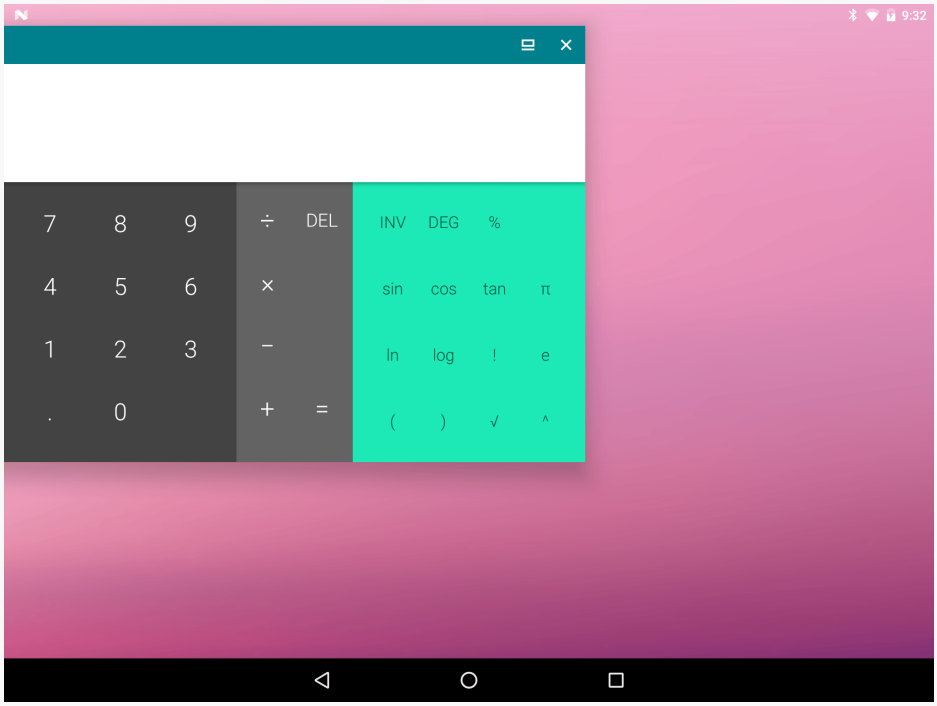

Figure 446: Calculator in Freeform Window

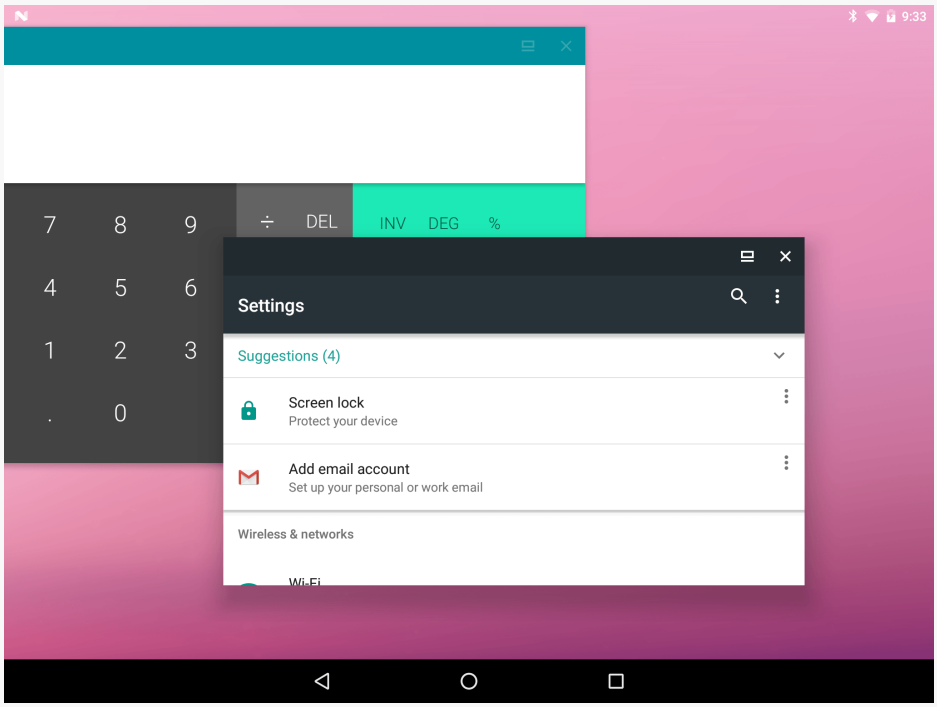

Figure 447: Calculator and Settings in Freeform Window

To undo this change, run:

```
adb shell settings put global enable_freeform_support 0
```

After a reboot, platform-level freeform multi-window support will be disabled again.

The Freecar App

Braden Farmer's Taskbar app is open source. All that it is doing is using documented APIs to describe how a window should be displayed in freeform mode, so one can imagine that home screen app developers might start offering a similar capability.

The `Introspection/Freecar` sample application is a simpler demonstration of launching freeform windows on devices where either "Force activities to be resizable" or the `enable_freeform_support` global setting is enabled. This is a clone of the earlier `Sidecar` sample, except this time the notification shade tile will launch the chosen activity in freeform mode.

API Level 16 added a version of `startActivity()` that takes both an `Intent` and a `Bundle` as parameters. The `Bundle` is a way of providing additional information to Android describing how the activity should be started. That `Bundle` is typically created via an `ActivityOptions` object, where you configure a set of options, call `toBundle()` on it to convert the options into a `Bundle`, then pass that `Bundle` to `startActivity()`.
